```

Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

TransformFunction implementation

The following code shows the [StringTokenizer](#) class.

```

class StringTokenizer : public TransformFunction
{
 virtual void processPartition(ServerInterface &srvInterface,
 PartitionReader &inputReader,
 PartitionWriter &outputWriter)
 {
 try {
 if (inputReader.getNumCols() != 1)
 vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputReader.getNumCols());

 do {
 const VString &sentence = inputReader.getStringRef(0);

 // If input string is NULL, then output is NULL as well
 if (sentence.isNull())
 {
 VString &word = outputWriter.getStringRef(0);
 word.setNull();
 outputWriter.next();
 }
 else
 {
 // Otherwise, let's tokenize the string and output the words
 std::string tmp = sentence.str();
 std::istringstream ss(tmp);

 do
 {
 std::string buffer;
 ss >> buffer;

 // Copy to output
 if (!buffer.empty()) {
 VString &word = outputWriter.getStringRef(0);
 word.copy(buffer);
 outputWriter.next();
 }
 } while (ss);
 }
 } while (inputReader.next() && !isCanceled());
 } catch(std::exception& e) {
 // Standard exception. Quit.
 vt_report_error(0, "Exception while processing partition: [%s]", e.what());
 }
 }
};

```

The `processPartition()` function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row and checking for cancellation before advancing. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, `processPartition()` first extracts the `VString` containing the text from the `PartitionReader` object. The `VString` class represents a Vertica string value (VARCHAR or CHAR). If there is input, it then tokenizes it and adds it to the output using the `PartitionWriter` object.

Similarly to reading input columns, the `PartitionWriter` class has functions for writing each type of data to the output row. In this case, the example calls the `PartitionWriter` object's `getStringRef()` function to allocate a new `VString` object to hold the token to output for the first column, and then copies the token's value into the `VString`.

TransformFunctionFactory implementation

The following code shows the factory class.

```

class TokenFactory : public TransformFunctionFactory
{
 // Tell Vertica that we take in a row with 1 string, and return a row with 1 string
 virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
 {
 argTypes.addVarchar();
 returnType.addVarchar();
 }

 // Tell Vertica what our return string length will be, given the input
 // string length
 virtual void getReturnType(ServerInterface &srvInterface,
 const SizedColumnTypes &inputTypes,
 SizedColumnTypes &outputTypes)
 {
 // Error out if we're called with anything but 1 argument
 if (inputTypes.getColumnCount() != 1)
 vt_report_error(0, "Function only accepts 1 argument, but %zu provided", inputTypes.getColumnCount());

 int input_len = inputTypes.getColumnType(0).getStringLength();

 // Our output size will never be more than the input size
 outputTypes.addVarchar(input_len, "words");
 }

 virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
 { return vt_createFuncObject<StringTokenizer>(srvInterface.allocator); }
};

```

In this example:

- The UDTF takes a VARCHAR column as input. To define the input column, `getPrototype()` calls `addVarchar()` on the `ColumnTypes` object that represents the input table.
- The UDTF returns a VARCHAR as output. The `getPrototype()` function calls `addVarchar()` to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length of the input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "words".

#### Note

You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, `getReturnType()` sets the column name to "". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the `createTransformFunction()` function in the example is boilerplate code. It just calls the `vt_returnFuncObj` macro with the name of the `TransformFunction` class associated with this factory class. This macro takes care of instantiating a copy of the `TransformFunction` class that Vertica can use to process data.

The `RegisterFactory` macro

The final step in creating your UDTF is to call the `RegisterFactory` macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The `RegisterFactory` macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```

Python example: string tokenizer

The following example shows a transform function that breaks an input string into tokens (based on whitespace). It is similar to the tokenizer examples for C++ and Java.

Loading and using the example

Create the library and function:

```
=> CREATE LIBRARY pyudtf AS '/home/dbadmin/udx/tokenize.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize AS NAME 'StringTokenizerFactory' LIBRARY pyudtf;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```
=> CREATE TABLE words (w VARCHAR);
CREATE TABLE
=> COPY words FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> this is a test of the python udtf
>> \.

=> SELECT tokenize(w) OVER () FROM words;
 token

this
is
a
test
of
the
python
udtf
(8 rows)
```

Setup

All Python UDXs must import the Vertica SDK.

```
import vertica_sdk
```

UDTF Python code

The following code defines the tokenizer and its factory.

```

class StringTokenizer(vertica_sdk.TransformFunction):
 """
 Transform function which tokenizes its inputs.
 For each input string, each of the whitespace-separated tokens of that
 string is produced as output.
 """
 def processPartition(self, server_interface, input, output):
 while True:
 for token in input.getString(0).split():
 output.setString(0, token)
 output.next()
 if not input.next():
 break

class StringTokenizerFactory(vertica_sdk.TransformFunctionFactory):
 def getPrototype(self, server_interface, arg_types, return_type):
 arg_types.addVarchar()
 return_type.addVarchar()
 def getReturnType(self, server_interface, arg_types, return_type):
 return_type.addColumn(arg_types.getColumnType(0), "tokens")
 def createTransformFunction(cls, server_interface):
 return StringTokenizer()

```

R example: log tokenizer

The **LogTokenizer** transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDX examples in the Vertica Github repository, <https://github.com/vertica/UDx-Examples>.

Load the function and library

Create the library and the function.

```

=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory' LIBRARY rLib FENCED;
CREATE FUNCTION

```

Querying data with the function

The following query shows how you can run a query with the UDTF.

```
=> SELECT machine,
 LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
FROM error_logs;
machine | Token
-----+-----
node001 | ERROR
node001 | 345
node001 | -
node001 | Broken
node001 | pipe
node001 | WARN
node001 | -
node001 | Nearly
node001 | filled
node001 | disk
node002 | ERROR
node002 | 111
node002 | -
node002 | Flooded
node002 | roads
node003 | ERROR
node003 | 222
node003 | -
node003 | Plain
node003 | old
node003 | broken
(21 rows)
```

UDTF R code

```

LogTokenizer <- function(input.data.frame, parameters.data.frame) {
 # Take the spliton parameter passed by the user and assign it to a variable
 # in the function so we can use that as our tokenizer.
 if (is.null(parameters.data.frame[["spliton"]])) {
 stop("NULL value for spliton! Token cannot be NULL.")
 } else {
 split.on <- as.character(parameters.data.frame[["spliton"]])
 }
 # Tokenize the string.
 tokens <- vector(length=0)
 for (string in input.data.frame[, 1]) {
 tokenized.string <- strsplit(string, split.on)
 for (token in tokenized.string) {
 tokens <- append(tokens, token)
 }
 }
 final.output <- data.frame(tokens)
 return(final.output)
}

```

```

LogTokenizerFactory <- function() {
 list(name = LogTokenizer,
 udxtype = c("transform"),
 intype = c("varchar"),
 outtype = c("varchar"),
 outtypecallback=LogTokenizerReturn,
 parameterstypecallback=LogTokenizerParameters)
}

```

```

LogTokenizerParameters <- function() {
 parameters <- list(datatype = c("varchar"),
 length = c("NA"),
 scale = c("NA"),
 name = c("spliton"))
 return(parameters)
}

```

```

LogTokenizerReturn <- function(arg.data.frame, parm.data.frame) {
 output.return.type <- data.frame(datatype = rep(NA,1),
 length = rep(NA,1),
 scale = rep(NA,1),
 name = rep(NA,1))
 output.return.type$datatype <- c("varchar")
 output.return.type$name <- c("Token")
 return(output.return.type)
}

```

### C++ example: multi-phase indexer

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the `MultiPhaseTransformFunctionFactory` including two `TransformFunctionPhase` subclasses that define the two phases in this UDTF.

```

class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory
{
public:
 /**
 * Extracts terms from documents.
 */
 class ForwardIndexPhase : public TransformFunctionPhase
 {

```

```

 outputTypes.addInt("corp_freq");
}

virtual TransformFunction *createTransformFunction(ServerInterface
 &srvInterface)
{ return vt_createFuncObj(srvInterface allocator, InvertedIndexBuilder); }
};
ForwardIndexPhase fwardIdxPh;
InvertedIndexPhase invIdxPh;
virtual void getPhases(ServerInterface &srvInterface,
 std::vector<TransformFunctionPhase *> &phases)
{
 fwardIdxPh.setPrepass(); // Process documents wherever they're originally stored.
 phases.push_back(&fwardIdxPh);
 phases.push_back(&invIdxPh);
}
virtual void getPrototype(ServerInterface &srvInterface,
 ColumnTypes &argTypes,
 ColumnTypes &returnType)
{
 // Expected input: (doc_id INTEGER, text VARCHAR).
 argTypes.addInt();
 argTypes.addVarchar();
 // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
 returnType.addVarchar();
 returnType.addInt();
 returnType.addInt();
 returnType.addInt();
}
};
RegisterFactory(InvertedIndexFactory);

```

Most of the code in this example is similar to the code in a [TransformFunctionFactory](#) class:

- Both [TransformFunctionPhase](#) subclasses implement the [getReturnType\(\)](#) function, which describes the output of each stage. This is similar to the [getReturnType\(\)](#) function from the [TransformFunctionFactory](#) class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF. The first phase calls [SizedColumnTypes::addVarcharPartitionColumn\(\)](#) (rather than just [addVarcharColumn\(\)](#) ) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls [SizedColumnTypes::addOrderColumn\(\)](#) to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as [addIntOrderColumn\(\)](#) ) so it can pass the data type of the original column through to the output column.

#### Note

Any order by column or partition by column set by the final phase of the UDTF in its [getReturnType\(\)](#) function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The [MultiPhaseTransformFunctionFactory](#) class implements the [getPrototype\(\)](#) function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the [TransformFunctionFactory::getPrototype\(\)](#) function.

The unique function implemented by the [MultiPhaseTransformFunctionFactory](#) class is [getPhases\(\)](#) . This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

The [MultiPhaseTransformFunctionFactory.getPhases\(\)](#) function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

#### Note

Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the `TransformFunctionPhase::setPrepass()` function of the first phase's `TransformFunctionPhase` instance from within the `getPhase()` function.

#### Notes

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each `TransformFunctionPhase::getReturnType()` implementation performs a sanity check on its input and output schemas. Your `TransformFunction` subclasses can also perform these checks in their `processPartition()` function.
- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode, Vertica may terminate UDTFs that use too much memory. See [Resource use for C++ UDXs](#).

#### Python example: multi-phase calculation

The following example shows a multi-phase transform function that computes the average value on a column of numbers in an input table. It first defines two transform functions, and then defines a factory that creates the phases using them.

See [AvgMultiPhaseUDT.py](#) in the examples distribution for the complete code.

#### Loading and using the example

Create the library and function:

```
=> CREATE LIBRARY pylib_avg AS '/home/dbadmin/udx/AvgMultiPhaseUDT.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION myAvg AS NAME 'MyAvgFactory' LIBRARY pylib_avg;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SELECT statements:

```
=> CREATE TABLE IF NOT EXISTS numbers(num FLOAT);
CREATE TABLE

=> COPY numbers FROM STDIN delimiter ',';
1
2
3
4
\

=> SELECT myAvg(num) OVER() FROM numbers;
average | ignored_rows | total_rows
-----+-----+-----
 2.5 | 0 | 4
(1 row)
```

#### Setup

All Python UDXs must import the Vertica SDK. This example also imports another library.

```
import vertica_sdk
import math
```

#### Component transform functions

A multi-phase transform function must define two or more `TransformFunction` subclasses to be used in the phases. This example uses two classes: `LocalCalculation`, which does calculations on local partitions, and `GlobalCalculation`, which aggregates the results of all `LocalCalculation` instances to calculate a final result.

In both functions, the calculation is done in the `processPartition()` function:

```

class LocalCalculation(vertica_sdk.TransformFunction):
 """
 This class is the first phase and calculates the local values for sum, ignored_rows and total_rows.
 """

 def setup(self, server_interface, col_types):
 server_interface.log("Setup: Phase0")
 self.local_sum = 0.0
 self.ignored_rows = 0
 self.total_rows = 0

 def processPartition(self, server_interface, input, output):
 server_interface.log("Process Partition: Phase0")

 while True:
 self.total_rows += 1

 if input.isNull(0) or math.isinf(input.getFloat(0)) or math.isnan(input.getFloat(0)):
 # Null, Inf, or Nan is ignored
 self.ignored_rows += 1
 else:
 self.local_sum += input.getFloat(0)

 if not input.next():
 break

 output.setFloat(0, self.local_sum)
 output.setInt(1, self.ignored_rows)
 output.setInt(2, self.total_rows)
 output.next()

```

```

class GlobalCalculation(vertica_sdk.TransformFunction):
 """
 This class is the second phase and aggregates the values for sum, ignored_rows and total_rows.
 """

 def setup(self, server_interface, col_types):
 server_interface.log("Setup: Phase1")
 self.global_sum = 0.0
 self.ignored_rows = 0
 self.total_rows = 0

 def processPartition(self, server_interface, input, output):
 server_interface.log("Process Partition: Phase1")

 while True:
 self.global_sum += input.getFloat(0)
 self.ignored_rows += input.getInt(1)
 self.total_rows += input.getInt(2)

 if not input.next():
 break

 average = self.global_sum / (self.total_rows - self.ignored_rows)

 output.setFloat(0, average)
 output.setInt(1, self.ignored_rows)
 output.setInt(2, self.total_rows)
 output.next()

```

A `MultiPhaseTransformFunctionFactory` ties together the individual functions as phases. The factory defines a `TransformFunctionPhase` for each function. Each phase defines `createTransformFunction()`, which calls the constructor for the corresponding `TransformFunction`, and `getReturnType()`.

The first phase, `LocalPhase`, follows.

```
class MyAvgFactory(vertica_sdk.MultiPhaseTransformFunctionFactory):
 """ Factory class """

 class LocalPhase(vertica_sdk.TransformFunctionPhase):
 """ Phase 1 """
 def getReturnType(self, server_interface, input_types, output_types):
 # sanity check
 number_of_cols = input_types.getColumnCount()
 if (number_of_cols != 1 or not input_types.getColumnType(0).isFloat()):
 raise ValueError("Function only accepts one argument (FLOAT)")

 output_types.addFloat("local_sum");
 output_types.addInt("ignored_rows");
 output_types.addInt("total_rows");

 def createTransformFunction(cls, server_interface):
 return LocalCalculation()
```

The second phase, `GlobalPhase`, does not check its inputs because the first phase already did. As with the first phase, `createTransformFunction` merely constructs and returns the corresponding `TransformFunction`.

```
class GlobalPhase(vertica_sdk.TransformFunctionPhase):
 """ Phase 2 """
 def getReturnType(self, server_interface, input_types, output_types):
 output_types.addFloat("average");
 output_types.addInt("ignored_rows");
 output_types.addInt("total_rows");

 def createTransformFunction(cls, server_interface):
 return GlobalCalculation()
```

After defining the `TransformFunctionPhase` subclasses, the factory instantiates them and chains them together in `getPhases()`.

```
ph0Instance = LocalPhase()
ph1Instance = GlobalPhase()

def getPhases(cls, server_interface):
 cls.ph0Instance.setPrepass()
 phases = [cls.ph0Instance, cls.ph1Instance]
 return phases
```

Python example: count elements

The following example details a UDTF that takes a partition of arrays, computes the count of each distinct array element in the partition, and outputs each element and its count as a row value. You can call the function on tables that contain multiple partitions of arrays.

The complete source code is in `/opt/vertica/sdk/examples/python/TransformFunctions.py`.

Loading and using the example

Load the library and create the transform function as follows:

```
=> CREATE OR REPLACE LIBRARY TransformFunctions AS '/home/dbadmin/examples/python/TransformFunctions.py' LANGUAGE 'Python';
=> CREATE TRANSFORM FUNCTION CountElements AS LANGUAGE 'Python' NAME 'countElementsUDTFactor' LIBRARY TransformFunctions;
```

You can create some data and then call the function on it, for example:

```

=> CREATE TABLE orders (storeID int, productIDs array[int]);
CREATE TABLE

=> INSERT INTO orders VALUES
 (1, array[101, 102, 103]),
 (1, array[102, 104]),
 (1, array[101, 102, 102, 201, 203]),
 (2, array[101, 202, 203, 202, 203]),
 (2, array[203]),
 (2, array[]);
OUTPUT

6
(1 row)

=> COMMIT;
COMMIT

=> SELECT storeID, CountElements(productIDs) OVER (PARTITION BY storeID) FROM orders;
storeID | element_count
-----+-----
 1 | {"element":101,"count":2}
 1 | {"element":102,"count":4}
 1 | {"element":103,"count":1}
 1 | {"element":104,"count":1}
 1 | {"element":201,"count":1}
 1 | {"element":202,"count":1}
 2 | {"element":101,"count":1}
 2 | {"element":202,"count":2}
 2 | {"element":203,"count":3}
(9 rows)

```

## Setup

All Python UDxs must import the Vertica SDK library:

```
import vertica_sdk
```

## Factory implementation

The `getPrototype()` method declares that the inputs and outputs can be of any type, which means that type enforcement must be done elsewhere:

```
def getPrototype(self, srv_interface, arg_types, return_type):
 arg_types.addAny()
 return_type.addAny()
```

`getReturnType()` validates that the only argument to the function is an array and that the return type is a row with 'element' and 'count' fields:

```
def getReturnType(self, srv_interface, arg_types, return_type):

 if arg_types.getColumnCount() != 1:
 srv_interface.reportError(1, 'countElements UDT should take exactly one argument')

 if not arg_types.getColumnType(0).isArrayType():
 srv_interface.reportError(2, 'Argument to countElements UDT should be an ARRAY')

 retRowFields = vertica_sdk.SizedColumnTypes.makeEmpty()
 retRowFields.addColumn(arg_types.getColumnType(0).getElementType(), 'element')
 retRowFields.addInt('count')
 return_type.addRowType(retRowFields, 'element_count')
```

The `countElementsUDTFFactory` class also contains a `createTransformFunction()` method that instantiates and returns the transform function.

#### Function implementation

The `processBlock()` method is called with a `BlockReader` and a `BlockWriter`, named `arg_reader` and `res_writer` respectively. The function loops through all the input arrays in a partition and uses a dictionary to collect the frequency of each element. To access elements of each input array, the method instantiates an `ArrayReader`. After collecting the element counts, the function writes each element and its count to a row. This process is repeated for each partition.

```
def processPartition(self, srv_interface, arg_reader, res_writer):

 elemCounts = dict()
 # Collect element counts for entire partition
 while (True):
 if not arg_reader.isNull(0):
 arr = arg_reader.getArray(0)
 for elem in arr:
 elemCounts[elem] = elemCounts.setdefault(elem, 0) + 1

 if not arg_reader.next():
 break

 # Write at least one value for each partition
 if len(elemCounts) == 0:
 elemCounts[None] = 0

 # Write out element counts as (element, count) pairs
 for pair in elemCounts.items():
 res_writer.setRow(0, pair)
 res_writer.next()
```

#### Python example: explode

The following example details a UDTF that accepts a one-dimensional array as input and outputs each element of the array as a separate row, similar to functions commonly known as [EXPLODE](#). Because this UDTF always accepts one array as input, you can explicitly mark it as a [one-to-many UDTF](#) in the factory function, which helps Vertica optimize query plans and allows users to write SELECT queries that include any expression and do not require an OVER clause.

The complete source code is in [/opt/vertica/sdk/examples/python/TransformFunctions.py](#).

#### Loading and using the example

Load the library and create the transform function as follows:

```
=> CREATE OR REPLACE LIBRARY PyTransformFunctions AS '/opt/vertica/sdk/examples/python/TransformFunctions.py' LANGUAGE 'Python';
CREATE LIBRARY

=> CREATE TRANSFORM FUNCTION py_explode AS LANGUAGE 'Python' NAME 'ExplodeFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```

=> CREATE TABLE reviews (id INTEGER PRIMARY KEY, sentiment VARCHAR(16), review ARRAY[VARCHAR(16), 32]);
CREATE TABLE

=> INSERT INTO reviews VALUES(1, 'Very Negative', string_to_array('This was the worst restaurant I have ever had the misfortune of eating at' USING
PARAMETERS collection_delimiter = ' ')),
 (2, 'Neutral', string_to_array('This restaurant is pretty decent' USING PARAMETERS collection_delimiter = ' ')),
 (3, 'Very Positive', string_to_array('Best restaurant in the Western Hemisphere' USING PARAMETERS collection_delimiter = ' ')),
 (4, 'Positive', string_to_array('Prices low for the area' USING PARAMETERS collection_delimiter = ' '));
OUTPUT

4
(1 row)

=> COMMIT;
COMMIT

=> SELECT id, sentiment, py_explode(review) FROM reviews; --no OVER clause because "is_exploder = True", see below
id | sentiment | element
-----+-----+-----
1 | Very Negative | This
1 | Very Negative | was
1 | Very Negative | the
1 | Very Negative | worst
1 | Very Negative | restaurant
1 | Very Negative | I
1 | Very Negative | have
...
3 | Very Positive | Western
3 | Very Positive | Hemisphere
4 | Positive | Prices
4 | Positive | low
4 | Positive | for
4 | Positive | the
4 | Positive | area
(30 rows)

```

## Setup

All Python UDxs must import the Vertica SDK library:

```
import vertica_sdk
```

## Factory implementation

The following code shows the `ExplodeFactory` class.

```

class ExplodeFactory(vertica_sdk.TransformFunctionFactory):
 def getPrototype(self, srv_interface, arg_types, return_type):
 arg_types.addAny()
 return_type.addAny()

 def getTransformFunctionProperties(cls, server_interface, arg_types):
 props = vertica_sdk.TransformFunctionFactory.Properties()
 props.is_exploder = True
 return props

 def getReturnType(self, srv_interface, arg_types, return_type):
 if arg_types.getColumnCount() != 1:
 srv_interface.reportError(1, 'explode UDT should take exactly one argument')
 if not arg_types.getColumnType(0).isArrayType():
 srv_interface.reportError(2, 'Argument to explode UDT should be an ARRAY')

 return_type.addColumn(arg_types.getColumnType(0).getElementType(), 'element')

 def createTransformFunction(cls, server_interface):
 return Explode()

```

In this example:

- The `getTransformFunctionProperties` method sets the `is_exploder` class property to True, explicitly marking the UDTF as one-to-many. This indicates that the function uses an OVER(PARTITION ROW) clause by default and thereby removes the need to specify an OVER clause when calling the UDTF. With `is_exploder` set to True, users can write SELECT queries that include any expression, unlike queries that use PARTITION BEST or PARTITION NODES.
- The `getReturnType` method verifies that the input contains only one argument and is of type ARRAY. The method also sets the return type to that of the elements in the input array.

Function implementation

The following code shows the `Explode` class:

```

class Explode(vertica_sdk.TransformFunction):
 """
 Transform function that turns an array into one row
 for each array element.
 """

 def processPartition(self, srv_interface, arg_reader, res_writer):
 while True:
 arr = arg_reader.getArrayReader(0)
 for elt in arr:
 res_writer.copyRow(elt)
 res_writer.next()
 if not arg_reader.next():
 break;

```

The `processPartition()` method accepts a single row of the input data, processes each element of the array, and then breaks the loop. The method accesses the elements of the array with an `ArrayReader` object and then uses an `ArrayWriter` object to write each element of the array to a separate output row. The UDTF calls `processPartition()` for each row of the input data.

User-defined load (UDL)

[COPY](#) offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The user-defined load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process. .

You use three types of UDL functions during development, one for each stage of the data-load process:

- [User-defined source](#) (UDSource): Controls how COPY obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.  
API support: C++, Java.
- [User-defined filter](#) (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple user-defined filters together, for example unzipping and then converting.  
API support: C++, Java, Python.
- [User-defined parser](#) (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a user-defined chunker (UDChunker, C++ only), to have the parser perform parallel parsing.  
API support: C++, Java, Python.

After the final step, COPY inserts the data into a table, or rejects it if the format is incorrect.

User-defined source

A user-defined source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a user-defined source to access the data from an HTTP source using cURL. While a given [COPY](#) statement can use specify only one user-defined source statement, the source function itself can pull data from multiple sources.

The [UDSource](#) class acquires data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a [UDSource](#), you must also implement a corresponding [SourceFactory](#).

In this section

- [UDSource class](#)
- [SourceFactory class](#)
- [C++ example: CurlSource](#)
- [C++ example: concurrent load](#)
- [Java example: FileSource](#)

UDSource class

You can subclass the [UDSource](#) class when you need to load data from a source type that COPY does not already support.

Each instance of your [UDSource](#) subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

UDSource methods

Your [UDSource](#) subclass must override [process\(\)](#) or [processWithMetadata\(\)](#) :

#### Note

[processWithMetadata\(\)](#) is available only for user-defined extensions (UDxs) written in the C++ programming language.

- [process\(\)](#) reads the raw input stream as one large file. If there are any errors or failures, the entire load fails.
- [processWithMetadata\(\)](#) is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data. By implementing [processWithMetadata\(\)](#) instead of [process\(\)](#) in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. [KafkaSource](#) and the Kafka parsers ( [KafkaAvroParser](#), [KafkaJSONParser](#), and [KafkaParser](#) ) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are cannot be parsed.

## Note

To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Additionally, you can override the other `UDSource` class methods.

### Source execution

The following sections detail the execution sequence each time a user-defined source is called. The following example overrides the `process()` method.

#### Setting Up

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the `UDSource` can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

#### Processing a Source

COPY calls `process()` repeatedly during query execution to read data and write it to the `DataBuffer` passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value `StreamState.OUTPUT_NEEDED`. When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in the data-load process. Returning `StreamState.DONE` indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

#### Tearing Down

COPY calls `destroy()` after the last time that `process()` is called. This method frees any resources reserved by the `setup()` or `process()` methods, such as file handles or network connections that the `setup()` method allocated.

### Accessors

A source can define two accessors, `getSize()` and `getUri()`.

COPY might call `getSize()` to estimate the number of bytes of data to be read before calling `process()`. This value is an estimate only and is used to indicate the file size in the `LOAD_STREAMS` table. Because Vertica can call this method before calling `setup()`, `getSize()` must not rely on any resources allocated by `setup()`.

This method should not leave any resources open. For example, do not save any file handles opened by `getSize()` for use by the `process()` method. Doing so can exhaust the available resources, because Vertica calls `getSize()` on all instances of your `UDSource` subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls `getUri()` during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this `UDSource`.

### API

[C++](#)

[Java](#)

The [UDSource](#) API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &output, LengthBuffer &output_lengths)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface);

virtual vint getSize();

virtual std::string getUri();
```

## SourceFactory class

If you write a source, you must also write a source factory. Your subclass of the `SourceFactory` class is responsible for:

- Performing the initial validation of the parameters passed to your `UDSource`.
- Setting up any data structures your `UDSource` instances need to perform their work. This information can include recording which nodes will read which data source.
- Creating one instance of your `UDSource` subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one `UDSource` instance per data source per executor node. You can also use multiple concurrent `UDSource` instances on each node. This behavior is called *concurrent load*. To support both options, `SourceFactory` has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

## SourceFactory methods

The `SourceFactory` class defines several methods. Your class must override `prepareUDSources()`; it may override the other methods.

## Setting up

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into the `plan()` method.
- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's file system, can be read only by a single specified host. You store the list of hosts to read the data source by calling the `setTargetNodes()` method on the `NodeSpecifyingPlanContext` object. This object is passed into your `plan()` method.
- Store any information that the individual hosts need to process the data sources in the `NodeSpecifyingPlanContext` instance passed to the `plan()` method. For example, you could store assignments that tell each host which data sources to process. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them. You store data in the `NodeSpecifyingPlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString()`.

### Note

`ParamWriter` offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.

## Creating sources

Vertica calls `prepareUDSources()` on all hosts that the `plan()` method selected to load data. This call instantiates and returns a list of `UDSource` subclass

instances. If you are not using concurrent load, return one `UDSource` for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an `ExecutorPlanContext` as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

#### Note

In the C++ API, the function that supports concurrent load is named `prepareUDSourcesExecutor()`. In the Java API the class provides two overloads of `prepareUDSources()`.

For concurrent load, you can find out how many threads are available on the node to run `UDSource` instances by calling `getLoadConcurrency()` on the `ExecutorPlanContext` that is passed in.

#### Defining parameters

Implement `getParameterTypes()` to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

#### Requesting threads for concurrent load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement `getDesiredThreads()`. Vertica calls this method before it calls `prepareUDSources()`, so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The `FilePortionSourceFactory` example implements this method; see [C++ example: concurrent load](#).

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing `isSourceApportionable()`. Returning `true` from this method does not guarantee that the source *will* apportion the load. However, returning `false` indicates that it will not try to do so. See [Apportioned load](#) for more information.

Often, a `SourceFactory` that implements `getDesiredThreads()` also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without ssapportioning.

#### API

[C++](#)

[Java](#)

The [SourceFactory](#) API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &svInterface, NodeSpecifyingPlanContext &planCtx);

// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
virtual std::vector< UDSource * > prepareUDSources(ServerInterface &svInterface,
 NodeSpecifyingPlanContext &planCtx);

virtual std::vector< UDSource * > prepareUDSourcesExecutor(ServerInterface &svInterface,
 ExecutorPlanContext &planCtx);

virtual void getParameterType(ServerInterface &svInterface,
 SizedColumnTypes ¶meterTypes);

virtual bool isSourceApportionable();

ssize_t getDesiredThreads(ServerInterface &svInterface,
 ExecutorPlanContext &planContext);
```

After creating your `SourceFactory`, you must register it with the `RegisterFactory` macro.

#### C++ example: CurlSource

The `CurlSource` example allows you to use cURL to open and read in a file over HTTP. The example provided is part of:

[/opt/vertica/sdk/examples/SourceFunctions/cURL.cpp](#) .

## Source implementation

This example uses the helper library available in [/opt/vertica/sdk/examples/HelperLibraries/](#) .

CurlSource loads the data in chunks. If the parser encounters an EndOfFile marker, then the `process()` method returns DONE. Otherwise, the method returns OUTPUT\_NEEDED and processes another chunk of data. The functions included in the helper library (such as `url_fread()` and `url_fopen()` ) are based on examples that come with the libcurl library. For an example, see <http://curl.haxx.se/libcurl/c/fopen.html>.

The `setup()` function opens a file handle and the `destroy()` function closes it. Both use functions from the helper library.

```
class CurlSource : public UDSource {private:
 URL_FILE *handle;
 std::string url;
 virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
 output.offset = url_fread(output.buf, 1, output.size, handle);
 return url_feof(handle) ? DONE : OUTPUT_NEEDED;
 }
public:
 CurlSource(std::string url) : url(url) {}
 void setup(ServerInterface &srvInterface) {
 handle = url_fopen(url.c_str(), "r");
 }
 void destroy(ServerInterface &srvInterface) {
 url_fclose(handle);
 }
};
```

## Factory implementation

`CurlSourceFactory` produces `CurlSource` instances.

```
class CurlSourceFactory : public SourceFactory {public:
 virtual void plan(ServerInterface &srvInterface,
 NodeSpecifyingPlanContext &planCtx) {
 std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
 /* Check parameters */
 if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
 vt_report_error(0, "You must provide a single URL.");
 }
 /* Populate planData */
 planCtx.getWriter().getStringRef("url").copy(
 srvInterface.getParamReader().getStringRef("url"));

 /* Assign Nodes */
 std::vector<std::string> executionNodes = planCtx.getClusterNodes();
 while (executionNodes.size() > 1) executionNodes.pop_back();
 // Only run on the first node in the list.
 planCtx.setTargetNodes(executionNodes);
 }
 virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface,
 NodeSpecifyingPlanContext &planCtx) {
 std::vector<UDSource*> retVal;
 retVal.push_back(vt_createFuncObj(srvInterface.allocator, CurlSource,
 planCtx.getReader().getStringRef("url").str()));
 return retVal;
 }
 virtual void getParameterType(ServerInterface &srvInterface,
 SizedColumnTypes ¶meterTypes) {
 parameterTypes.addVarchar(65000, "url");
 }
};
RegisterFactory(CurlSourceFactory);
```

C++ example: concurrent load

The `FilePortionSource` example demonstrates the use of concurrent load. This example is a refinement of the `FileSource` example. Each input file is divided into portions and distributed to `FilePortionSource` instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on `FilePortionSourceFactory`. The full code for the example is located in `/opt/vertica/sdk/examples/ApportionLoadFunctions`. The distribution also includes a Java version of this example.

Loading and using the example

Load and use the `FilePortionSource` example as follows.

```
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';

=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
-> NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;

=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets = '0,380000,820000');

=> COPY t WITH SOURCE FilePortionSource(file='g2/*.dat', nodes='e0,e1,e2', local_min_portion_size = 2097152);
```

Implementation

Concurrent load affects the source factory in two places, `getDesiredThreads()` and `prepareUDSourcesExecutor()`.

`getDesiredThreads()`

The `getDesiredThreads()` member function determines the number of threads to request. Vertica calls this member function on each executor node before calling `prepareUDSourcesExecutor()`.

The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
 ExecutorPlanContext &planCtx) {
 const std::string filename = srvInterface.getParamReader().getStringRef("file").str();

 std::vector<std::string> paths;
 // expand the glob - at least one thread per source.
 ...

 // figure out how to assign files to sources
 const std::string nodeName = srvInterface.getCurrentNodeName();
 const size_t nodeId = planCtx.getWriter().getIntRef(nodeName);
 const size_t numNodes = planCtx.getTargetNodes().size();

 if (!planCtx.canApportionSource()) {
 /* no apportioning, so the number of files is the final number of sources */
 std::vector<std::string> *expanded =
 vt_createFuncObject<std::vector<std::string> >(srvInterface.allocator, paths);
 /* save expanded paths so we don't have to compute expansion again */
 planCtx.getWriter().setPointer("expanded", expanded);
 return expanded->size();
 }
 // ...
}
```

If the source can be apportioned, then `getDesiredThreads()` uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.

```

else if (srvInterface.getParamReader().containsParameter("offsets")) {

 // if the offsets are specified, then we will have a fixed number of portions per file.
 // Round-robin assign offsets to nodes.
 // ...

 /* Construct the portions that this node will actually handle.
 * This isn't changing (since the offset assignments are fixed),
 * so we'll build the Portion objects now and make them available
 * to prepareUDSourcesExecutor() by putting them in the ExecutionContext.
 */
 /* We don't know the size of the last portion, since it depends on the file
 * size. Rather than figure it out here we will indicate it with -1 and
 * defer that to prepareUDSourcesExecutor().
 */
 std::vector<Portion> *portions =
 vt_createFuncObject<std::vector<Portion>>(srvInterface.allocator);

 for (std::vector<size_t>::const_iterator offset = offsets.begin();
 offset != offsets.end(); ++offset) {
 Portion p(*offset);
 p.is_first_portion = (offset == offsets.begin());
 p.size = (offset + 1 == offsets.end() ? -1 : (*(offset + 1) - *offset));

 if ((offset - offsets.begin()) % numNodes == nodeId) {
 portions->push_back(p);
 srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %ld, size = %ld]",
 offset - offsets.begin(), p.offset, p.size);
 }
 }
}

```

The function now has all the portions and thus the number of portions:

```

planCtxt.getWriter().setPointer("portions", portions);

/* total number of threads we want is the number of portions per file, which is fixed */
return portions->size() * expanded->size();
} // end of "offsets" parameter

```

If offsets were not provided, the function divides the file into portions dynamically, one portion per thread. This discussion omits the details of this computation. There is no point in requesting more threads than are available, so the function calls [getMaxAllowedThreads\(\)](#) on the [PlanContext](#) (an argument to the function) to set an upper bound:

```

if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
 return paths.size();
}

```

See the full example for the details of how this function divides the file into portions.

This function uses the [vt\\_createFuncObject](#) template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in [prepareUDSourcesExecutor\(\)](#).

[prepareUDSourcesExecutor\(\)](#)

The [prepareUDSourcesExecutor\(\)](#) member function, like [getDesiredThreads\(\)](#), has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates [UDSource](#) instances for them.

If the function is called with offsets, [prepareUDSourcesExecutor\(\)](#) calls [prepareCustomizedPortions\(\)](#). This function follows.

```

/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
 ExecutorPlanContext &planCtx,
 std::vector<UDSource *> &sources,
 const std::vector<std::string> &expandedPaths,
 std::vector<Portion> &portions) {
 for (std::vector<std::string>::const_iterator filename = expandedPaths.begin();
 filename != expandedPaths.end(); ++filename) {
 /*
 * the "portions" vector contains the portions which were generated in
 * "getDesiredThreads"
 */
 const size_t fileSize = getFileSize(*filename);
 for (std::vector<Portion>::const_iterator portion = portions.begin();
 portion != portions.end(); ++portion) {
 Portion fportion(*portion);
 if (fportion.size == -1) {
 /* as described above, this means from the offset to the end */
 fportion.size = fileSize - portion->offset;
 sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
 *filename, fportion));
 } else if (fportion.size > 0) {
 sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
 *filename, fportion));
 }
 }
 }
}

```

If [prepareUDSourcesExecutor\(\)](#) is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then [prepareUDSourcesExecutor\(\)](#) calls [prepareGeneratedPortions\(\)](#) to create the portions. This function begins by calling [getLoadConcurrency\(\)](#) on the plan context to find out how many threads are available.

```

void prepareGeneratedPortions(ServerInterface &svrInterface,
 ExecutorPlanContext &planCtx,
 std::vector<UDSource *> &sources,
 std::map<std::string, Portion> initialPortions) {

 if ((ssize_t) initialPortions.size() >= planCtx.getLoadConcurrency()) {
 /* all threads will be used, don't bother splitting into portions */

 for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin();
 file != initialPortions.end(); ++file) {
 sources.push_back(vt_createFuncObject<FilePortionSource>(svrInterface.allocator,
 file->first, file->second));
 } // for
 return;
 } // if

 // Now we can split files to take advantage of potentially-unused threads.
 // First sort by size (descending), then we will split the largest first.

 // details elided...
}

```

For more information

See the source code for the full implementation of this example.

## Java example: FileSource

The example shown in this section is a simple UDL Source function named `FileSource`. This function loads data from files stored on the host's file system (similar to the standard `COPY` statement). To call `FileSource`, you must supply a parameter named `file` that contains the absolute path to one or more files on the host file system. You can specify multiple files as a comma-separated list.

The `FileSource` function also accepts an optional parameter, named `nodes`, that indicates which nodes should load the files. If you do not supply this parameter, the function defaults to loading data on the initiator node only. Because this example is simple, the nodes load only the files from their own file systems. Any files in the `file` parameter must exist on all of the hosts in the `nodes` parameter. The `FileSource` UDSOURCE attempts to load all of the files in the `file` parameter on all of the hosts in the `nodes` parameter.

## Generating files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example `UDSource` function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```

#!/usr/bin/python
Save this file as UDLDataGen.py
import string
import random
import sys
import os

Read in the dictionary file to provide random words. Assumes the words
file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
 if len(line) > 6:
 wordDict.append(line.strip())

MAXSTR = 4 # Maximum number of words to concatenate
NUMROWS = 1000 # Number of rows of data to generate
#FILEPATH = '/tmp/UDLdata.txt' # Final filename to use for UDL source
TMPFILE = '/tmp/UDLtemp.txt' # Temporary filename.

Generate a random string by concatenating several words together. Max
number of words set by MAXSTR
def randomWords():
 words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
 sentence = " ".join(words)
 return sentence

Create a temporary data file that will be moved to a node. Number of
rows for the file is set by NUMROWS. Adds the name of the node which will
get the file, to show which node loaded the data.
def generateFile(node):
 outFile = open(TMPFILE, 'w')
 for line in xrange(NUMROWS):
 outFile.write('{0}|{1}|{2}\n'.format(line,randomWords(),node))
 outFile.close()

Copy the temporary file to a node. Only works if passwordless SSH login
is enabled, which it is for the database administrator account on
Vertica hosts.
def copyFile(fileName,node):
 os.system('scp "%s" "%s:%s"' % (TMPFILE, node, fileName))

Loop through the comma-separated list of nodes given in the first
parameter, creating and copying data files whose full comma-separated
paths are passed in the second parameter
for node in [x.strip() for x in sys.argv[1].split(',')]:
 for fileName in [y.strip() for y in sys.argv[2].split(',')]:
 print "generating file", fileName, "for", node
 generateFile(node)
 print "Copying file to",node
 copyFile(fileName,node)

```

You call this script by giving it a comma-separated list of hosts to receive the files and a comma-separated list of absolute paths of files to generate. For example:

```
$ python UDLDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003 /tmp/UDLdata01.txt,/tmp/UDLdata02.txt,UDLdata03.txt
```

This script generates files that contain a thousand rows of columns delimited with the pipe character (|). These columns contain an index value, a set of random words, and the node for which the file was generated, as shown in the following output sample:

```
0|megabits embanks|v_vmart_node0001
1|unneatly|v_vmart_node0001
2|self-precipitation|v_vmart_node0001
3|antihistamine scalados Vatter|v_vmart_node0001
```

Loading and using the example

Load and use the [FileSource](#) UDSOURCE as follows:

```
=> --Load library and create the source function
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLib.jar'
-> LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE SOURCE File as LANGUAGE 'JAVA' NAME
-> 'com.mycompany.UDL.FileSourceFactory' LIBRARY JavaLib;
CREATE SOURCE FUNCTION
=> --Create a table to hold the data loaded from files
=> CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
=> -- Copy a single file from the currently host using the FileSource
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt');
Rows Loaded

 1000
(1 row)

=> --See some of what got loaded.
=> SELECT * FROM t WHERE i < 5 ORDER BY i;
i| text | node
-----+-----+-----
0 | megabits embanks | v_vmart_node0001
1 | unneatly | v_vmart_node0001
2 | self-precipitation | v_vmart_node0001
3 | antihistamine scalados Vatter | v_vmart_node0001
4 | fate-menaced toilworn | v_vmart_node0001
(5 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Now load a file from three hosts. All of these hosts must have a file
=> -- named /tmp/UDLdata01.txt, each with different data
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt',
-> nodes='v_vmart_node0001,v_vmart_node0002,v_vmart_node0003');
Rows Loaded

 3000
(1 row)

=> --Now see what has been loaded
=> SELECT * FROM t WHERE i < 5 ORDER BY i,node ;
i| text | node
-----+-----+-----
0 | megabits embanks | v_vmart_node0001
0 | nimble-eyed undupability frowsier | v_vmart_node0002
0 | Circean nonrepellence nonnasality | v_vmart_node0003
1 | unneatly | v_vmart_node0001
1 | floatmaker trabacolos hit-in | v_vmart_node0002
1 | revelrous treatableness Halleck | v_vmart_node0003
2 | self-precipitation | v_vmart_node0001

## Parser implementation

The following code shows the source of the `FileSource` class that reads a file from the host file system. The constructor, which is called by `FileSourceFactory.prepareUDSources()`, gets the absolute path for the file containing the data to be read. The `setup()` method opens the file and the `destroy()` method closes it. The `process()` method reads from the file into a buffer provided by the instance of the `DataBuffer` class passed to it as a parameter. If the read operation filled the output buffer, it returns `OUTPUT_NEEDED`. This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then `process()` returns `DONE` to indicate it has finished processing the data source.

```

package com.mycompany.UDL;

import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileReader;
import java.io.IOException;
import java.io.RandomAccessFile;

import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSource extends UDSource {

 private String filename; // The file for this UDSource to read
 private RandomAccessFile reader; // handle to read from file

 // The constructor just stores the absolute filename of the file it will

```

```
return StreamState.OUTPUT_NEEDED;
```

## Factory implementation

The following code is a modified version of the example Java UDSOURCE function provided in the Java UDX support package. You can find the full example in `/opt/vertica/sdk/examples/JavaUDx/UDLFuctions/com/vertica/JavaLibs/FileSourceFactory.java`. Its override of the `plan()` method verifies that the user supplied the required `file` parameter. If the user also supplied the optional `nodes` parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the `plan()` method stores their values in the plan context object.

```
package com.mycompany.UDL;

import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.NodeSpecifyingPlanContext;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.SourceFactory;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSourceFactory extends SourceFactory {

 // Called once on the initiator host to do initial setup. Checks
 // parameters and chooses which nodes will do the work.
 @Override
 public void plan(ServerInterface srvInterface,
 NodeSpecifyingPlanContext planCtx) throws UdfException {

 String nodes; // stores the list of nodes that will load data

 // Get copy of the parameters the user supplied to the UDSOURCE
 // function call.
 ParamReader args = srvInterface.getParamReader();

 // A list of nodes that will perform work. This gets saved as part
 // of the plan context.
 ArrayList<String> executionNodes = new ArrayList<String>();

 // First, ensure the user supplied the file parameter
 if (!args.containsParameter("file")) {
 // Without a file parameter, we cannot continue. Throw an
 // exception that will be caught by the Java UDX framework.
 throw new UdfException(0, "You must supply a file parameter");
 }

 // If the user specified nodes to read the file, parse the
 // comma-separated list and save. Otherwise, assume just the
 // Initiator node has the file to read.
 if (args.containsParameter("nodes")) {
 nodes = args.getString("nodes");

 // Get list of nodes in cluster, to ensure that the node the
 // user specified actually exists. The list of nodes is available
 // from the planCtx (plan context) object.
 ArrayList<String> clusterNodes = planCtx.getClusterNodes();
```

```

String fileNames = params.getString("filesFor" + myName);

// Note that you can also be lazy and directly grab the parameters
// the user passed to the UDSource function in the COPY statement directly
// by getting parameters from the ServerInterface object. I.e.:

//String fileNames = srvInterface.getParamReader().getString("file");

// Split comma-separated list into a single list.
String[] fileList = fileNames.split(",");
for (int i = 0; i < fileList.length; i++){
 // Instantiate a FileSource object (which is a subclass of UDSource)
 // to read each file. The constructor for FileSource takes the
 // file name of the
 retVal.add(new FileSource(fileList[i]));
}

// Return the collection of FileSource objects. They will be called,
// in turn, to read each of the files.
return retVal;
}

// Declares which parameters that this factory accepts.
@Override
public void getParameterTypes(ServerInterface srvInterface,
 SizedColumnTypes parameterTypes) {
 parameterTypes.addVarchar(65000, "file");
 parameterTypes.addVarchar(65000, "nodes");
}

```

## User-defined filter

User-defined filter functions allow you to manipulate data obtained from a source in various ways. For example, a filter can:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a [UDFilter](#) , you must also implement a corresponding [FilterFactory](#) .

See [UDFilter class](#) and [FilterFactory class](#) for API details.

### In this section

- [UDFilter class](#)
- [FilterFactory class](#)
- [Java example: ReplaceCharFilter](#)
- [C++ example: converting encoding](#)

## UDFilter class

The [UDFilter](#) class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A [UDFilter](#) is instantiated by a corresponding [FilterFactory](#) on each host in the Vertica cluster that is performing filtering for the data source.

### UDFilter methods

Your [UDFilter](#) subclass must override [process\(\)](#) or [processWithMetadata\(\)](#) :

## Note

`processWithMetadata()` is available only for user-defined extensions (UDxs) written in the C++ programming language.

- `process()` reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement `process()` when the upstream source implements `processWithMetadata()`, but it might result in parsing errors.
- `processWithMetadata()` is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data. By implementing `processWithMetadata()` instead of `process()` in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. [KafkaSource](#) and the Kafka parsers ( [KafkaAvroParser](#), [KafkaJSONParser](#), and [KafkaParser](#) ) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted. Using `processWithMetadata()` with your `UDFilter` subclass enables you to write an internal filter that integrates the record length metadata from the source into the data stream, producing a single byte stream with boundary information to help parsers extract and process individual messages. [KafkaInsertDelimiters](#) and [KafkaInsertLengths](#) use this mechanism to insert message boundary information into Kafka data streams.

## Note

To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Optionally, you can override other `UDFilter` class methods.

### Filter execution

The following sections detail the execution sequence each time a user-defined filter is called. The following example overrides the `process()` method.

### Setting Up

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

### Filtering Data

COPY calls `process()` repeatedly during query execution to filter data. The method receives two instances of the `DataBuffer` class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The `process()` method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by `StreamState`:

- `OUTPUT_NEEDED` if the filter needs more room in its output buffer.
- `INPUT_NEEDED` if the filter has run out of input data (but the data source has not yet been fully processed).
- `DONE` if the filter has processed all of the data in the data source.
- `KEEP_GOING` if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your `process()` method must set the `offset` property in each `DataBuffer`. In the input buffer, set it to the number of bytes that the method successfully read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to `process()` to resume reading and writing data at the correct points in the buffers.

Your `process()` method also needs to check the `InputState` object passed to it to determine if there is more data in the data source. When this object is equal to `END_OF_FILE`, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, `process()` must return `DONE`.

### Tearing Down

COPY calls `destroy()` after the last time it calls `process()`. This method frees any resources reserved by the `setup()` or `process()` methods. Vertica calls this method after the `process()` method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call `setup()` on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your `destroy()` method should leave an object of your `UDFilter` subclass in a state where the `setup()` method can prepare it to be reused.

[C++](#)

[Java](#)

[Python](#)

The [UDFilter](#) API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state, DataBuffer &output, LengthBuffer &output_lengths);

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input, LengthBuffer &input_lengths, InputState input_state, DataBuffer &output, LengthBuffer &output_lengths)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface);
```

### FilterFactory class

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the [FilterFactory](#) class.

Your subclass performs the initial validation and planning of the function execution and instantiates [UDFilter](#) objects on each host that will be filtering data.

Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

### FilterFactory methods

The [FilterFactory](#) class defines the following methods. Your subclass must override the [prepare\(\)](#) method. It may override the other methods.

### Setting up

Vertica calls [plan\(\)](#) once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a [ParamReader](#) object from the instance of [ServerInterface](#) passed into your [plan\(\)](#) method.
- Store any information that the individual hosts need in order to filter data in the [PlanContext](#) instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The [plan\(\)](#) method runs only on the initiator node, and the [prepare\(\)](#) method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the [PlanContext](#) by getting a [ParamWriter](#) object from the [getWriter\(\)](#) method. You then write parameters by calling methods on the [ParamWriter](#) such as [setString](#) .

### Note

[ParamWriter](#) offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

### Creating filters

Vertica calls [prepare\(\)](#) to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.

### Defining parameters

Implement [getParameterTypes\(\)](#) to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

[C++](#)

[Java](#)

[Python](#)

The [FilterFactory](#) API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PlanContext &planCtx);

virtual UDFilter * prepare(ServerInterface &srvInterface, PlanContext &planCtx)=0;

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes ¶meterTypes);
```

After creating your [FilterFactory](#) , you must register it with the [RegisterFactory](#) macro.

Java example: [ReplaceCharFilter](#)

The example in this section demonstrates creating a [UDFilter](#) that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.

Always remember that the input and output streams in a [UDFilter](#) are actually binary data. If you are performing character transformations using a [UDFilter](#) , convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

Loading and using the example

The example [UDFilter](#) has two required parameters. The [from\\_char](#) parameter specifies the character to be replaced, and the [to\\_char](#) parameter specifies the replacement character. Load and use the [ReplaceCharFilter](#) UDFilter as follows:

```

=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLib.jar'
->LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'
->name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;
CREATE FILTER FUNCTION
=> CREATE TABLE t (text VARCHAR);
CREATE TABLE
=> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Mary had a little lamb
>> a man, a plan, a canal, Panama
>> \.

=> SELECT * FROM t;
 text

Mzry hzd z little lzmb
z mzn, z plzn, z cznzl, Pznmz
(2 rows)

=> --Calling the filter with incorrect parameters returns errors
=> COPY t from stdin with filter ReplaceCharFilter();
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [
ReplaceCharFilter], error code: 0

```

#### Parser implementation

The [ReplaceCharFilter](#) class reads the data stream, replacing each occurrence of a user-specified character with another character.

## Factory implementation

**ReplaceCharFilterFactory** requires two parameters ( **from\_char** and **to\_char** ). The **plan()** method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The **prepare()** method gets the parameter values and passes them to the **ReplaceCharFilter** objects, which it instantiates, to perform the filtering.

```
package com.vertica.JavaLibs;

import java.util.ArrayList;
import java.util.Vector;

import com.vertica.sdk.FilterFactory;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDFilter;
import com.vertica.sdk.UdfException;

public class ReplaceCharFilterFactory extends FilterFactory {

 // Run on the initiator node to perform verification and basic setup.
 @Override
 public void plan(ServerInterface srvInterface, PlanContext planCtx)
 throws UdfException {
 ArrayList<String> args =
 srvInterface.getParamReader().getParamNames();

 // Ensure user supplied two arguments
 if (!(args.contains("from_char") && args.contains("to_char"))) {
 throw new UdfException(0, "You must supply two parameters" +
 " to ReplaceChar: 'from_char' and 'to_char'");
 }

 // Verify that the from_char is a single character.
 String fromChar = srvInterface.getParamReader().getString("from_char");
 if (fromChar.length() != 1) {
 String message = String.format("Replacechar expects a single " +
 "character in the 'from_char' parameter. Got length %d",
 fromChar.length());
 throw new UdfException(0, message);
 }

 // Save the from character in the plan context, to be read by
 // prepare() method.
 planCtx.getWriter().setString("fromChar", fromChar);

 // Ensure to character parameter is a single character
 String toChar = srvInterface.getParamReader().getString("to_char");
 if (toChar.length() != 1) {
 String message = String.format("Replacechar expects a single " +
 "character in the 'to_char' parameter. Got length %d",
 toChar.length());
 throw new UdfException(0, message);
 }

 // Save the to character in the plan data
 planCtx.getWriter().setString("toChar", toChar);
 }

 // Called on every host that will filter data. Must instantiate the
 // UDFilter subclass.
 @Override
 public UDFilter prepare(ServerInterface srvInterface, PlanContext planCtx)
```

```

 throws UdiException {
// Get data stored in the context by the plan() method.
String fromChar = planCtx.getWriter().getString("fromChar");
String toChar = planCtx.getWriter().getString("toChar");

// Instantiate a filter object to perform filtering.
return new ReplaceCharFilter(fromChar, toChar);
}

// Describe the parameters accepted by this filter.
@Override
public void getParameterType(ServerInterface srvInterface,
 SizedColumnTypes parameterTypes) {
 parameterTypes.addVarchar(1, "from_char");
 parameterTypes.addVarchar(1, "to_char");
}
}

```

### C++ example: converting encoding

The following example shows how you can convert encoding for a file from one type to another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at </opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp> .

### Filter implementation

```

class Iconverter : public UDFilter{
private:
 std::string fromEncoding, toEncoding;
 iconv_t cd; // the conversion descriptor opened
 uint converted; // how many characters have been converted
protected:
 virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
 InputState input_state, DataBuffer &output)
 {
 char *input_buf = (char *)input.buf + input.offset;
 char *output_buf = (char *)output.buf + output.offset;
 size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;
 // end of input
 if (input_state == END_OF_FILE && inBytesLeft == 0)
 {
 // Gnu libc iconv doc says, it is good practice to finalize the
 // outbuffer for stateful encodings (by calling with null inbuffer).
 //
 // http://www.gnu.org/software/libc/manual/html_node/Generic-Conversion-Interface.html
 iconv(cd, NULL, NULL, &output_buf, &outBytesLeft);
 // output buffer can be updated by this operation
 output.offset = output.size - outBytesLeft;
 return DONE;
 }
 size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
 // if conversion is successful, we ask for more input, as input has not reached EOF.
 StreamState retStatus = INPUT_NEEDED;
 if (ret == (size_t)(-1))
 {
 // seen an error
 switch (errno)
 {
 {
 case E2BIG:
 // input size too big, not a problem, ask for more output.
 retStatus = OUTPUT_NEEDED;
 break;
 case EINVAL:

```

```

 // input stops in the middle of a byte sequence, not a problem, ask for more input
 retStatus = input_state == END_OF_FILE ? DONE : INPUT_NEEDED;
 break;
case EILSEQ:
 // invalid sequence seen, throw
 // TODO: reporting the wrong byte position
 vt_report_error(1, "Invalid byte sequence when doing %u-th conversion", converted);
case EBADF:
 // something wrong with descriptor, throw
 vt_report_error(0, "Invalid descriptor");
default:
 vt_report_error(0, "Uncommon Error");
 break;
}
}
else converted += ret;
// move position pointer
input.offset = input.size - inBytesLeft;
output.offset = output.size - outBytesLeft;
return retStatus;
}
public:
 lconverter(const std::string &from, const std::string &to)
 : fromEncoding(from), toEncoding(to), converted(0)
 {
 // note "to encoding" is first argument to iconv...
 cd = iconv_open(to.c_str(), from.c_str());
 if (cd == (iconv_t)(-1))
 {
 // error when creating converters.
 vt_report_error(0, "Error initializing iconv: %m");
 }
 }
 ~lconverter()
 {
 // free iconv resources;
 iconv_close(cd);
 }
};

```

Factory implementation

```

class IconverterFactory : public FilterFactory{
public:
 virtual void plan(ServerInterface &srvInterface,
 PlanContext &planCtxt) {
 std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
 /* Check parameters */
 if (!(args.size() == 0 ||
 (args.size() == 1 && find(args.begin(), args.end(), "from_encoding")
 != args.end()) || (args.size() == 2
 && find(args.begin(), args.end(), "from_encoding") != args.end()
 && find(args.begin(), args.end(), "to_encoding") != args.end())) {
 vt_report_error(0, "Invalid arguments. Must specify either no arguments, or "
 "'from_encoding' alone, or 'from_encoding' and 'to_encoding'.");
 }
 /* Populate planData */
 // By default, we do UTF16->UTF8, and x->UTF8
 VString from_encoding = planCtxt.getWriter().getStringRef("from_encoding");
 VString to_encoding = planCtxt.getWriter().getStringRef("to_encoding");
 from_encoding.copy("UTF-16");
 to_encoding.copy("UTF-8");
 if (args.size() == 2)
 {

 to_encoding.copy(srvInterface.getParamReader().getStringRef("to_encoding"));
 }
 else if (args.size() == 1)
 {
 from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
 }
 if (!from_encoding.length()) {
 vt_report_error(0, "The empty string is not a valid from_encoding value");
 }
 if (!to_encoding.length()) {
 vt_report_error(0, "The empty string is not a valid to_encoding value");
 }
 }
 virtual UDFilter* prepare(ServerInterface &srvInterface,
 PlanContext &planCtxt) {
 return vt_createFuncObj(srvInterface.allocator, Iconverter,
 planCtxt.getReader().getStringRef("from_encoding").str(),
 planCtxt.getReader().getStringRef("to_encoding").str());
 }
 virtual void getParameterType(ServerInterface &srvInterface,
 SizedColumnTypes ¶meterTypes) {
 parameterTypes.addVarchar(32, "from_encoding");
 parameterTypes.addVarchar(32, "to_encoding");
 }
};
RegisterFactory(IconverterFactory);

```

## User-defined parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use user-defined parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you can load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

[COPY](#) supports a single user-defined parser that you can use with a [user-defined source](#) and zero or more instances of a [user-defined filter](#). If you implement a [UDParser class](#), you must also implement a corresponding [ParserFactory](#).

Sometimes, you can improve the performance of your parser by adding a *chunker*. A chunker divides up the input and uses multiple threads to parse it. Chunkers are available only in the C++ API. For details, see [Cooperative parse](#) and [UDChunker class](#). Under special circumstances you can further improve performance by using [apportioned load](#), an approach where multiple Vertica nodes parse the input.

In this section

- [UDParser class](#)
- [UDChunker class](#)
- [ParserFactory class](#)
- [C++ example: BasicIntegerParser](#)
- [C++ example: ContinuousIntegerParser](#)
- [Java example: numeric text](#)
- [Java example: JSON parser](#)
- [C++ example: delimited parser and chunker](#)
- [Python example: complex types JSON parser](#)

UDParser class

You can subclass the `UDParser` class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.

During parser execution, Vertica always calls three methods: `setup()`, `process()`, and `destroy()`. It might also call `getRejectedRecord()`.

UDParser constructor

The `UDParser` class performs important initialization required by all subclasses, including initializing the `StreamWriter` object used by the parser. Therefore, your constructor must call `super()`.

UDParser methods

Your `UDParser` subclass must override `process()` or `processWithMetadata()`:

#### Note

`processWithMetadata()` is available only for user-defined extensions (UDxs) written in the C++ programming language.

- `process()` reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement `process()` with a source or filter that implements `processWithMetadata()`, but it might result in parsing errors. You can implement `process()` when the upstream source or filter implements `processWithMetadata()`, but it might result in parsing errors.
- `processWithMetadata()` is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data. By implementing `processWithMetadata()` instead of `process()` in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. [KafkaSource](#) and Kafka parsers ([KafkaAvroParser](#), [KafkaJSONParser](#), and [KafkaParser](#)) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.

#### Note

To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Additionally, you must override `getRejectedRecord()` to return information about rejected records.

Optionally, you can override the other `UDParser` class methods.

Parser execution

The following sections detail the execution sequence each time a user-defined parser is called. The following example overrides the `process()` method.

Setting up

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the `process()` method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Parsing

COPY calls `process()` repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by `InputState` :

- **OK** : currently at the start of or in the middle of a stream
- **END\_OF\_FILE** : no further data is available.
- **END\_OF\_CHUNK** : the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
- **START\_OF\_PORTION** : the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the `getPortion()` method to access the offset and size of the portion.
- **END\_OF\_PORTION** : the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The `process()` method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is *not* automatically null-terminated.

A parser has an associated `StreamWriter` object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on `StreamWriter` to write that value to the output stream. See [Writing Data](#) for more information about these methods.

A single call to `process()` might write several rows of data. When your parser finishes processing a row of data, it must call `next()` on its `StreamWriter` to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your `process()` method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by `StreamState` :

- **INPUT\_NEEDED** : the parser has reached the end of the buffer and needs more data to parse.
- **DONE** : the parser has reached the end of the input data stream.
- **REJECT** : the parser has rejected the last row of data it read (see [Rejecting Rows](#)).

Tearing down

COPY calls `destroy()` after the last time that `process()` is called. It frees any resources reserved by the `setup()` or `process()` method.

Vertica calls this method after the `process()` method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call `setup()` on the object again and have it parse the data in a new data stream. Therefore, write your `destroy()` method so that it leaves an instance of your `UDParser` subclass in a state where `setup()` can be safely called again.

Reporting rejections

If `process()` rejects a row, Vertica calls `getRejectedRecord()` to report it. Usually, this method returns an instance of the `RejectedRecord` class with details of the rejected row.

Writing data

A parser has an associated `StreamWriter` object, which you access by calling `getStreamWriter()` . In your `process()` implementation, use the `set Type ()` methods on the `StreamWriter` object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type `long` to the fourth column (index 3) in the current row:

```
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

`StreamWriter` provides methods for all the basic types, such as `setBooleanValue()` , `setStringValue()` , and so on. See the API documentation for a complete list of `StreamWriter` methods, including options that take primitive types or explicitly set entries to null.

Rejecting rows

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a `RejectedRecord` object, or in fields on your `UDParser` subclass, until they are needed.
2. Updating the row's position in the input buffer by updating `input.offset` so it can resume parsing with the next row.

3. Signaling that it has rejected a row by returning with the value `StreamState.REJECT`.
4. Returning an instance of the `RejectedRecord` class with the details about the rejected row.

### Breaking up large loads

Vertica provides two ways to break up large loads. [Apportioned load](#) allows you to distribute a load among several database nodes. [Cooperative parse](#) (C++ only) allows you to distribute a load among several threads on one node.

### API

[C++](#)

[Java](#)

[Python](#)

The `UDParser` API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
 LengthBuffer &input_lengths, InputState input_state)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual RejectedRecord getRejectedRecord();
```

### UDChunker class

You can subclass the `UDChunker` class to allow your parser to support [Cooperative parse](#). This class is available only in the C++ API.

Fundamentally, a `UDChunker` is a very simplistic parser. Like `UDParser`, it has the following three methods: `setup()`, `process()`, and `destroy()`. You must override `process()`; you may override the others. This class has one additional method, `alignPortion()`, which you must implement if you want to enable [Apportioned load](#) for your `UDChunker`.

### Setting up and tearing down

As with `UDParser`, you can define initialization and cleanup code for your chunker. Vertica calls `setup()` before the first call to `process()` and `destroy()` after the last call to `process()`. Your object might be reused among multiple load sources, so make sure that `setup()` completely initializes all fields.

### Chunking

Vertica calls `process()` to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- `OK`: the input buffer begins at the start of or in the middle of a stream.
- `END_OF_FILE`: no further data is available.
- `END_OF_PORTION`: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is `END_OF_FILE`, the chunker should set the `input.offset` marker to `input.size` and return `DONE`. Returning `INPUT_NEEDED` is an error.

If the input state is `OK`, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the `input.offset` marker with the byte after the end of the last record in the buffer and return `CHUNK_ALIGNED`. For example, if the input is "abc~def" and "~" is a record terminator, this method should set `input.offset` to 4, the position of "d". If `process()` reaches the end of the input without finding a record boundary, it should return `INPUT_NEEDED`.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is `END_OF_PORTION`, the chunker should behave as it does for an input state of `OK`, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The `process()` method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return `KEEP_GOING`. Failing to return `KEEP_GOING` has several consequences, such as preventing your user from being able to cancel the query.

See [C++ example: delimited parser and chunker](#) for an example of the `process()` method using chunking.

### Aligning portions

If your chunker supports apportioned load, implement the `alignPortion()` method. Vertica calls this method one or more times, before calling `process()`, to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- `START_OF_PORTION`: the beginning of the buffer corresponds to the start of the portion. You can use the `getPortion()` method to access the offset and size of the portion.
- `OK`: the input buffer is in the middle of a portion.
- `END_OF_PORTION`: the end of the buffer corresponds to the end of the portion or beyond the end of a portion.
- `END_OF_FILE`: no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set `input.offset` to this position and return one of the following values:

- `DONE`, if it found a chunk. `input.offset` is the first byte of the chunk.
- `INPUT_NEEDED`, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of `END_OF_FILE`.
- `REJECT`, if the portion (not buffer) does not contain the start of any chunk.

### API

The [UDChunker](#) API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &svInterface,
 SizedColumnTypes &returnType);

virtual StreamState alignPortion(ServerInterface &svInterface,
 DataBuffer &input, InputState state);

virtual StreamState process(ServerInterface &svInterface,
 DataBuffer &input, InputState input_state)=0;

virtual void cancel(ServerInterface &svInterface);

virtual void destroy(ServerInterface &svInterface,
 SizedColumnTypes &returnType);
```

### ParserFactory class

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the `ParserFactory` class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The `ParserFactory` class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

### Setting up

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.
- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the `PlanContext`

instance passed in through the `planCtxt` parameter. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them. You store data in the `PlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString`.

#### Note

`ParamWriter` offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

### Creating parsers

Vertica calls `prepare()` on each node to create and initialize your parser, using data stored by the `plan()` method.

### Defining parameters

Implement `getParameterTypes()` to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

### Defining parser outputs

Implement `getParserReturnType()` to define the data types of the table columns that the parser outputs. If applicable, `getParserReturnType()` also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the `argType` and `perColumnParamReader` arguments and verifies that it can output the appropriate data types. If `getParserReturnType()` is prepared to output the data types, it calls methods on the `SizedColumnTypes` object passed in the `returnType` argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARBINARY), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
- For Time/Timestamp types (with or without time zone), specify its precision (-1 means unspecified).
- For ARRAY types, specify the maximum number of elements.
- For all other types, no length or precision specification is required.

### Supporting cooperative parse

To support [Cooperative parse](#), implement `prepareChunker()` and return an instance of your `UDChunker` subclass. If `isChunkerApportionable()` returns `true`, then it is an error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

### Supporting apportioned load

To support [Apportioned load](#), your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement `isParserApportionable()` and return `true`. To indicate that the chunker can apportion a load, implement `isChunkerApportionable()` and return `true`.

The `isChunkerApportionable()` method takes a `ServerInterface` as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return `true` from this method if and only if the factory can create a chunker for this input.

### API

[C++](#)

[Java](#)

[Python](#)

The [ParserFactory](#) API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planContext, const SizedColumnTypes &returnTypes)=0;

virtual UDFParser * prepare(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtx, const SizedColumnTypes &returnTypes)=0;

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes ¶meterTypes);

virtual void getParserReturnType(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtx, const SizedColumnTypes &argTypes, SizedColumnTypes &returnTypes);

virtual bool isParserApportionable();

// C++ API only:
virtual bool isChunkerApportionable(ServerInterface &srvInterface);

virtual UDChunker * prepareChunker(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, PlanContext &planCtx, const SizedColumnTypes &returnTypes);
```

If you are using [Apportioned load](#) to divide a single input into multiple load streams, implement [isParserApportionable\(\)](#) and/or [isChunkerApportionable\(\)](#) and return **true** . Returning **true** from these methods does not guarantee that Vertica *will* apportion the load. However, returning **false** from both indicates that it will not try to do so.

If you are using [Cooperative parse](#) , implement [prepareChunker\(\)](#) and return an instance of your [UDChunker](#) subclass. Cooperative parse is supported only for the C++ API.

Vertica calls the [prepareChunker\(\)](#) method *only* for unfenced functions. This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement [isChunkerApportionable\(\)](#) and return **true** .

After creating your [ParserFactory](#) , you must register it with the [RegisterFactory](#) macro.

#### C++ example: BasicIntegerParser

The [BasicIntegerParser](#) example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see [C++ example: ContinuousIntegerParser](#) .

Loading and using the example

Load and use the [BasicIntegerParser](#) example as follows.

```
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';

=> CREATE PARSE BasicIntegerParser AS
LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;

=> CREATE TABLE t (i integer);

=> COPY t FROM stdin WITH PARSE BasicIntegerParser();
0
1
2
3
4
5
\.
```

#### Implementation

The `BasicIntegerParser` class implements only the `process()` method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the `input.offset` marker and checks the input state. It then writes the output.

```
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
 InputState input_state) {
 // WARNING: This implementation is not trying for efficiency.
 // It is trying for simplicity, for demonstration purposes.

 size_t start = input.offset;
 const size_t end = input.size;

 do {
 bool found_newline = false;
 size_t numEnd = start;
 for (; numEnd < end; numEnd++) {
 if (input.buf[numEnd] < '0' || input.buf[numEnd] > '9') {
 found_newline = true;
 break;
 }
 }

 if (!found_newline) {
 input.offset = start;
 if (input_state == END_OF_FILE) {
 // If we're at end-of-file,
 // emit the last integer (if any) and return DONE.
 if (start != end) {
 writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
 writer->next();
 }
 return DONE;
 } else {
 // Otherwise, we need more data.
 return INPUT_NEEDED;
 }
 }

 writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
 writer->next();

 start = numEnd + 1;
 } while (true);
}
```

In the factory, the `plan()` method is a no-op; there are no parameters to check. The `prepare()` method instantiates the parser using the macro provided by the SDK:

```
virtual UDParser* prepare(ServerInterface &srvInterface,
 PerColumnParamReader &perColumnParamReader,
 PlanContext &planCtx,
 const SizedColumnTypes &returnType) {

 return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);
}
```

The `getParserReturnType()` method declares the single output:

```

virtual void getParserReturnType(ServerInterface &srvInterface,
 PerColumnParamReader &perColumnParamReader,
 PlanContext &planCtx,
 const SizedColumnTypes &argTypes,
 SizedColumnTypes &returnType) {
 // We only and always have a single integer column
 returnType.addInt(argTypes.getColumn(0));
}

```

As for all UDxs written in C++, the example ends by registering its factory:

```
registerFactory(BasicIntegerParserFactory);
```

C++ example: ContinuousIntegerParser

The [ContinuousIntegerParser](#) example is a variation of [BasicIntegerParser](#) . Both examples parse integers from input strings. [ContinuousIntegerParser](#) uses [Continuous load](#) to read data.

Loading and using the example

Load the [ContinuousIntegerParser](#) example as follows.

```

=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';

=> CREATE PARSER ContinuousIntegerParser AS
LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
LIBRARY ContinuousIntegerParserLib;

```

Use it in the same way that you use [BasicIntegerParser](#) . See [C++ example: BasicIntegerParser](#) .

Implementation

[ContinuousIntegerParser](#) is a subclass of [ContinuousUDParser](#) . Subclasses of [ContinuousUDParser](#) place the processing logic in the `run()` method.

```

virtual void run() {

 // This parser assumes a single-column input, and
 // a stream of ASCII integers split by non-numeric characters.
 size_t pos = 0;
 size_t reserved = cr.reserve(pos+1);
 while (!cr.isEof() || reserved == pos + 1) {
 while (reserved == pos + 1 && isdigit(*ptr(pos))) {
 pos++;
 reserved = cr.reserve(pos + 1);
 }

 std::string st(ptr(), pos);
 writer->setInt(0, strToInt(st));
 writer->next();

 while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
 pos++;
 reserved = cr.reserve(pos + 1);
 }
 cr.seek(pos);
 pos = 0;
 reserved = cr.reserve(pos + 1);
 }
}

```

For a more complex example of a [ContinuousUDParser](#) , see [ExampleDelimitedParser](#) in the examples. (See [Downloading and running Udx example code](#).) [ExampleDelimitedParser](#) uses a chunker; see [C++ example: delimited parser and chunker](#) .

## Java example: numeric text

This `NumericTextParser` example parses integer values spelled out in words rather than digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The separator defaults to the pipe (|) character.
- Ignores extra spaces and the capitalization of the words used to spell out the digits.
- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven, eight, nine.
- Assumes that the words spelling out an integer are separated by at least one space.
- Rejects any row of data that cannot be completely parsed into integers.
- Generates an error, if the output table has a non-integer column.

## Loading and using the example

Load and use the parser as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSEr NumericTextParser AS LANGUAGE 'java'
-> NAME 'com.myCompany.UDParser.NumericTextParserFactory'
-> LIBRARY JavaLib;
CREATE PARSEr FUNCTION
=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSEr NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> One
>> Two
>> One Two Three
>> \
=> SELECT * FROM t ORDER BY i;
|

| 1
| 2
| 123
(3 rows)

=> DROP TABLE t;
DROP TABLE
=> -- Parse multi-column input
=> CREATE TABLE t (i INTEGER, j INTEGER);
CREATE TABLE
=> COPY t FROM stdin WITH PARSEr NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> One | Two
>> Two | Three
>> One Two Three | four Five Six

## Parser implementation

The following code implements the parser.

```

 }
 return value;
}

// Vertica calls this method if the parser rejected a row of data
// to find out what went wrong and add to the proper logs. Just gathers
// information stored in fields and returns it in an object.
@Override
public RejectedRecord getRejectedRecord() throws UdfException {
 return new RejectedRecord(rejectedReason,rejectedRow.toCharArray(),
 rejectedRow.length(), "\n");
}

```

## ParserFactory implementation

The following code implements the parser factory.

**NumericTextParser** accepts a single optional parameter named **separator** . This parameter is defined in the **getParameterType()** method, and the **plan()** method stores its value. **NumericTextParser** outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the **getParserReturnType()** method throws an exception.

```

package com.myCompany.UDParser;

import java.util.regex.Pattern;

import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ParserFactory;
import com.vertica.sdk.PerColumnParamReader;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;
import com.vertica.sdk.VerticaType;

public class NumericTextParserFactory extends ParserFactory {

 // Called once on the initiator host to check the parameters and set up the
 // context data that hosts performing processing will need later.
 @Override
 public void plan(ServerInterface srvInterface,
 PerColumnParamReader perColumnParamReader,
 PlanContext planCtx) {

 String separator = "|"; // assume separator is pipe character

 // See if a parameter was given for column separator
 ParamReader args = srvInterface.getParamReader();
 if (args.containsParameter("separator")) {
 separator = args.getString("separator");
 if (separator.length() > 1) {
 throw new UdfException(0,
 "Separator parameter must be a single character");
 }
 if (Pattern.quote(separator).matches("[a-zA-Z]")) {
 throw new UdfException(0,
 "Separator parameter cannot be a letter");
 }
 }
 }
}

```

```

// Save separator character in the Plan Data
ParamWriter context = planCtxt.getWriter();
context.setString("separator", separator);
}

// Define the data types of the output table that the parser will return.
// Mainly, this just ensures that all of the columns in the table which
// is the target of the data load are integer.
@Override
public void getParserReturnType(ServerInterface srvInterface,
 PerColumnParamReader perColumnParamReader,
 PlanContext planCtxt,
 SizedColumnTypes argTypes,
 SizedColumnTypes returnType) {

 // Get access to the output table's columns
 for (int i = 0; i < argTypes.getColumnCount(); i++) {
 if (argTypes.getColumnType(i).isInt()) {
 // Column is integer... add it to the output
 returnType.addInt(argTypes.getColumnType(i));
 } else {
 // Column isn't an int, so throw an exception.
 // Technically, not necessary since the
 // UDX framework will automatically error out when it sees a
 // discrepancy between the type in the target table and the
 // types declared by this method. Throwing this exception will
 // provide a clearer error message to the user.
 String message = String.format(
 "Column %d of output table is not an Int", i + 1);
 throw new UdfException(0, message);
 }
 }
}

// Instantiate the UDXParser subclass named NumericTextParser. Passes the
// separator character as a parameter to the constructor.
@Override
public UDXParser prepare(ServerInterface srvInterface,
 PerColumnParamReader perColumnParamReader, PlanContext planCtxt,
 SizedColumnTypes returnType) throws UdfException {
 // Get the separator character from the context
 String separator = planCtxt.getReader().getString("separator");
 return new NumericTextParser(separator);
}

// Describe the parameters accepted by this parser.
@Override
public void getParameterType(ServerInterface srvInterface,
 SizedColumnTypes parameterTypes) {
 parameterTypes.addVarchar(1, "separator");
}
}

```

#### Java example: JSON parser

The JSON Parser consumes a stream of JSON objects. Each object must be well formed and on a single line in the input. Use line breaks to delimit the objects. The parser uses the field names as keys in a map, which become column names in the table. You can find the code for this example in `/opt/vertica/packages/flexible/examples`. This directory also contains an example data file.

This example uses the `setRowFromMap()` method to write data.

Loading and using the example

Load the library and define the JSON parser, using the third-party library ( [gson-2.2.4.jar](#) ) as follows. See the comments in `JsonParser.java` for a download URL:

```
-> CREATE LIBRARY json
-> AS '/opt/vertica/packages/flextable/examples/java/output/json.jar'
-> DEPENDS '/opt/vertica/bin/gson-2.2.4.jar' language 'java';
CREATE LIBRARY

-> CREATE PARSEr JsonParser AS LANGUAGE 'java'
-> NAME 'com.vertica.flex.JsonParserFactory' LIBRARY json;
CREATE PARSEr FUNCTION
```

You can now define a table and then use the JSON parser to load data into it, as follows:

```
-> CREATE TABLE mountains(name varchar(64), type varchar(32), height integer);
CREATE TABLE

-> COPY mountains FROM '/opt/vertica/packages/flextable/examples/mountains.json'
-> WITH PARSEr JsonParser();
{ RECORD 1 }--
Rows Loaded | 2

-> SELECT * from mountains;
{ RECORD 1 }-----
name | Everest
type | mountain
height | 29029
{ RECORD 2 }-----
name | Mt St Helens
type | volcano
height |
```

The data file contains a value (`hike_safety`) that was not loaded because the table definition did not include that column. The data file follows:

```
{ "name": "Everest", "type": "mountain", "height": 29029, "hike_safety": 34.1 }
{ "name": "Mt St Helens", "type": "volcano", "hike_safety": 15.4 }
```

### Implementation

The following code shows the `process()` method from `JsonParser.java`. The parser attempts to read the input into a `Map`. If the read is successful, the JSON Parser calls `setRowFromMap()` :

```

@Override
public StreamState process(ServerInterface srvInterface, DataBuffer input,
 InputState inputState) throws UdfException, DestroyInvocation {
 clearReject();
 StreamWriter output = getStreamWriter();

 while (input.offset < input.buf.length) {
 ByteBuffer lineBytes = consumeNextLine(input, inputState);

 if ((lineBytes == null) {
 return StreamState.INPUT_NEEDED;
 }

 String lineString = StringUtils.newString(lineBytes);

 try {
 Map<String, Object> map = gson.fromJson(lineString, parseType);

 if (map == null) {
 continue;
 }

 output.setRowFromMap(map);
 // No overrides needed, so just call next() here.
 output.next();
 } catch (Exception ex) {
 setReject(lineString, ex);
 return StreamState.REJECT;
 }
 }
}

```

The factory, `JsonParserFactory.java`, instantiates and returns a parser in the `prepare()` method. No additional setup is required.

#### C++ example: delimited parser and chunker

The `ExampleDelimitedUDChunker` class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input. `ExampleDelimitedParser` is a `ContinuousUDParser` subclass that uses this chunker.

#### Loading and using the example

Load and use the example as follows.

```

=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSE ExampleDelimitedParser AS
 LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
 LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSE ExampleDelimitedParser();
0
1
2
3
4
5
6
7
8
9
\.
```

Chunker implementation

This chunker supports apportioned load. The `alignPortion()` method finds the beginning of the first complete record in the current portion and aligns the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```
StreamState ExampleDelimitedUDChunker::alignPortion(
 ServerInterface &srvInterface,
 DataBuffer &input, InputState state)
{
 /* find the first record terminator. Its record belongs to the previous portion */
 void *buf = reinterpret_cast<void *>(input.buf + input.offset);
 void *term = memchr(buf, recordTerminator, input.size - input.offset);

 if (term) {
 /* record boundary found. Align to the start of the next record */
 const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
 input.offset += chunkSize
 + sizeof(char) /* length of record terminator */;

 /* input.offset points at the start of the first complete record in the portion */
 return DONE;
 } else if (state == END_OF_FILE || state == END_OF_PORTION) {
 return REJECT;
 } else {
 VIAssert(state == START_OF_PORTION || state == OK);
 return INPUT_NEEDED;
 }
}
```

The `process()` method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of `alignPortion()`, so the example calls it to do part of the division.

```

StreamState ExampleDelimitedUDChunker::process(
 ServerInterface &srvInterface,
 DataBuffer &input,
 InputState input_state)
{
 const size_t termLen = 1;
 const char *terminator = &recordTerminator;

 if (pastPortion) {
 /*
 * Previous state was END_OF_PORTION, and the last chunk we will produce
 * extends beyond the portion we started with, into the next portion.
 * To be consistent with alignPortion(), that means finding the first
 * record boundary, and setting the chunk to be at that boundary.
 * Fortunately, this logic is identical to aligning the portion (with
 * some slight accounting for END_OF_FILE!)
 */
 const StreamState findLastTerminator = alignPortion(srvInterface, input);

 switch (findLastTerminator) {
 case DONE:
 return DONE;
 case INPUT_NEEDED:
 if (input_state == END_OF_FILE) {
 /* there is no more input where we might find a record terminator */
 input.offset = input.size;
 return DONE;
 }
 return INPUT_NEEDED;
 default:
 VIAssert("Invalid return state from alignPortion()");
 }
 return findLastTerminator;
 }
}

```

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.

```

 size_t ret = input.offset, term_index = 0;
 for (size_t index = input.offset; index < input.size; ++index) {
 const char c = input.buf[index];
 if (c == terminator[term_index]) {
 ++term_index;
 if (term_index == termLen) {
 ret = index + 1;
 term_index = 0;
 }
 continue;
 } else if (term_index > 0) {
 index -= term_index;
 }

 term_index = 0;
 }

 if (input_state == END_OF_PORTION) {
 /*
 * Regardless of whether or not a record was found, the next chunk will extend
 * into the next portion.
 */
 pastPortion = true;
 }
}

```

Finally, `process()` moves the input offset and returns.

```
// if we were able to find some rows, move the offset to point at the start of the next (potential) row, or end of block
if (ret > input.offset) {
 input.offset = ret;
 return CHUNK_ALIGNED;
}

if (input_state == END_OF_FILE) {
 input.offset = input.size;
 return DONE;
}

return INPUT_NEEDED;
```

Factory implementation

The file `ExampleDelimitedParser.cpp` defines a factory that uses this `UDChunker`. The chunker supports apportioned load, so the factory implements `isChunkerApportionable()`:

```
virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
 ParamReader params = srvInterface.getParamReader();
 if (params.containsParameter("disable_chunker") && params.getBoolRef("disable_chunker")) {
 return false;
 } else {
 return true;
 }
}
```

The `prepareChunker()` method creates the chunker:

```
virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
 PerColumnParamReader &perColumnParamReader,
 PlanContext &planCtx,
 const SizedColumnTypes &returnType)
{
 ParamReader params = srvInterface.getParamReader();
 if (params.containsParameter("disable_chunker") && params.getBoolRef("disable_chunker")) {
 return NULL;
 }

 std::string recordTerminator("\n");

 ParamReader args(srvInterface.getParamReader());
 if (args.containsParameter("record_terminator")) {
 recordTerminator = args.getStringRef("record_terminator").str();
 }

 return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface, allo\
cator,
 recordTerminator[0]);
}
```

Python example: complex types JSON parser

The following example details a `UDParser` that takes a JSON object and parses it into complex types. For this example, the parser assumes the input data are arrays of rows with two integer fields. The input records should be separated by newline characters. If any row fields aren't specified by the JSON input, the function parses those fields as `NULL`.

The source code for this UDParser also contains a factory method for parsing rows that have an integer and an array of integer fields. The implementation of the parser is independent of the return type in the factory, so you can create factories with different return types that all point to the `ComplexJsonParser()` class in the `prepare()` method. The complete source code is in </opt/vertica/sdk/examples/python/UDParsers.py> .

Loading and using the example

Load the library and create the parser as follows:

```
=> CREATE OR REPLACE LIBRARY UDParsers AS '/home/dbadmin/examples/python/UDParsers.py' LANGUAGE 'Python';
=> CREATE PARSE ComplexJsonParser AS LANGUAGE 'Python' NAME 'ArrayJsonParserFactory' LIBRARY UDParsers;
```

You can now define a table and then use the JSON parser to load data into it, for example:

```
=> CREATE TABLE orders (a bool, arr array[row(a int, b int)]);
CREATE TABLE

=> COPY orders (arr) FROM STDIN WITH PARSER ComplexJsonParser();
[]
[{"a":1, "b":10}]
[{"a":1, "b":10}, {"a":null, "b":10}]
[{"a":1, "b":10}, {"a":10, "b":20}]
[{"a":1, "b":10}, {"a":null, "b":null}]
[{"a":1, "b":2}, {"a":3, "b":4}, {"a":5, "b":6}, {"a":7, "b":8}, {"a":9, "b":10}, {"a":11, "b":12}, {"a":13, "b":14}]
\

=> SELECT * FROM orders;
a | arr
-----+-----
| []
| [{"a":1,"b":10}]
| [{"a":1,"b":10},{"a":null,"b":10}]
| [{"a":1,"b":10},{"a":10,"b":20}]
| [{"a":1,"b":10},{"a":null,"b":null}]
| [{"a":1,"b":2}, {"a":3,"b":4}, {"a":5,"b":6}, {"a":7,"b":8}, {"a":9,"b":10}, {"a":11,"b":12}, {"a":13,"b":14}]
(6 rows)
```

Setup

All Python UDxs must import the Vertica SDK library. `ComplexJsonParser()` also requires the json library.

```
import vertica_sdk
import json
```

Factory implementation

The `prepare()` method instantiates and returns a parser:

```
def prepare(self, srvInterface, perColumnParamReader, planCtx, returnType):
 return ComplexJsonParser()
```

`getParserReturnType()` declares that the return type must be an array of rows that each have two integer fields:

```
def getParserReturnType(self, rvInterface, perColumnParamReader, planCtx, argTypes, returnType):
 fieldTypes = vertica_sdk.SizedColumnTypes.makeEmpty()
 fieldTypes.addInt('a')
 fieldTypes.addInt('b')
 returnType.addArrayType(vertica_sdk.SizedColumnTypes.makeRowType(fieldTypes, 'elements'), 64, 'arr')
```

Parser implementation

The `process()` method reads in data with an `InputBuffer` and then splits that input data on the newline character. The method then passes the processed data to the `writeRows()` method. `writeRows()` turns each data row into a JSON object, checks the type of that JSON object, and then writes the appropriate value or object to the output.

```
class ComplexJsonParser(vertica_sdk.UDParser):

 leftover = ""

 def process(self, srvInterface, input_buffer, input_state, writer):
 input_buffer.setEncoding('utf-8')

 self.count = 0
 rec = self.leftover + input_buffer.read()
 row_lst = rec.split('\n')
 self.leftover = row_lst[-1]
 self.writeRows(row_lst[:-1], writer)
 if input_state == InputState.END_OF_FILE:
 self.writeRows([self.leftover], writer)
 return StreamState.DONE
 else:
 return StreamState.INPUT_NEEDED

 def writeRows(self, str_lst, writer):
 for s in str_lst:
 stripped = s.strip()
 if len(stripped) == 0:
 return
 elif len(stripped) > 1 and stripped[0:2] == "//":
 continue
 jsonValue = json.loads(stripped)
 if type(jsonValue) is list:
 writer.setArray(0, jsonValue)
 elif jsonValue is None:
 writer.setNull(0)
 else:
 writer.setRow(0, jsonValue)
 writer.next()
```

## Load parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- **Distributed load:** Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.
- **Cooperative parse:** A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See [Cooperative parse](#).
- **Apportioned load:** Vertica divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See [Apportioned load](#).

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See [Combining cooperative parse and apportioned load](#).

In this section

- [Cooperative parse](#)
- [Apportioned load](#)
- [Combining cooperative parse and apportioned load](#)

## Cooperative parse

By default, Vertica parses a data source in a single thread on one database node. You can optionally use *cooperative parse* to parse a source using multiple threads on a node. More specifically, data from a source passes through a *chunker* that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See [Fenced and unfenced modes.](#))

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunkers are created by parser factories. At load time, Vertica first calls the `UDChunker` to divide the input into chunks and then calls the `UDParser` to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See [Combining cooperative parse and apportioned load.](#)

#### How Vertica divides a load

When Vertica receives data from a source, it calls the chunker's `process()` method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the `process()` method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the `process()` method on the parser.

#### Implementing cooperative parse

To implement cooperative parse, perform the following actions:

- Subclass `UDChunker` and implement `process()` .
- In your `ParserFactory` , implement `prepareChunker()` to return a `UDChunker` .

See [C++ example: delimited parser and chunker](#) for a `UDChunker` that also supports apportioned load.

#### Apportioned load

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apportioned load* . Among the parsers built into Vertica, the default (delimited) parser supports apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See [Combining cooperative parse and apportioned load.](#)

#### How Vertica apports a load

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The `SourceFactory` breaks the input into portions and assigns them to execution nodes. Each `Portion` consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a `UDSource` for the given portion.

The `UDParser` first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that *begin* in the assigned portion, regardless of where they end. Most of this work occurs within the `process()` method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses [Cooperative parse](#) , then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

#### Implementing apportioned load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your `SourceFactory` subclass:

- Implement `isSourceApportionable()` and return `true` .
- Implement `plan()` to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context ( `PlanContext::getWriter()` ).
- Implement `prepareUDSources()` . Vertica calls this method on each execution node with the plan context created by the factory. This method returns the `UDSource` instances to be used for this node's assigned portions.
- If sources can take advantage of parallelism, you can implement `getDesiredThreads()` to request a number of threads for each source. See [SourceFactory class](#) for more information about this method.

In your `UDSource` subclass, implement `process()` as you would for any other source, using the assigned portion. You can retrieve this portion with `getPortion()` .

In your `ParserFactory` subclass:

- Implement `isParserApportionable()` and return `true` .
- If your parser uses a `UDChunker` that supports apportioned load, implement `isChunkerApportionable()` .

In your `UDParser` subclass:

- Write your `UDParser` subclass to operate on portions rather than whole sources. You can do so by handling the stream states `PORTION_START` and `PORTION_END` , or by using the `ContinuousUDParser` API. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.
- Handle the special case of a portion containing no record start by returning without writing any output.

In your `UDChunker` subclass, implement `alignPortion()` . See [Aligning Portions](#) .

Example

The SDK provides a C++ example of apportioned load in the `ApportionLoadFunctions` directory:

- `FilePortionSource` is a subclass of `UDSource` .
- `DelimFilePortionParser` is a subclass of `ContinuousUDParser` .

Use these classes together. You could also use `FilePortionSource` with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';
=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';
=> CREATE SOURCE FilePortionSource AS
LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;
=> CREATE PARSER DelimFilePortionParser AS
LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter = '|',
record_terminator = '~');
```

Combining cooperative parse and apportioned load

You can enable both [Cooperative parse](#) and [Apportioned load](#) in the same parser, allowing Vertica to decide how to load data.

Deciding how to divide a load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires [SourceFactory](#) support. Given a suitable [UDSource](#) , at planning time Vertica calls the [isParserApportionable\(\)](#) method on the [ParserFactory](#) . If this method returns [true](#) , Vertica apports the load.

If [isParserApportionable\(\)](#) returns [false](#) but [isChunkerApportionable\(\)](#) returns [true](#) , then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apports the load.

If neither of these methods returns [true](#) , then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but [prepareChunker\(\)](#) does not return a [UDChunker](#) instance, Vertica reports an error.

Executing apportioned, cooperative loads

If a load uses both apportioned load and cooperative parse, Vertica uses the [SourceFactory](#) to break the input into portions. It then assigns the portions to execution nodes. See [How Vertica Apports a Load](#) .

On the execution node, Vertica calls the chunker's [alignPortion\(\)](#) method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's [process\(\)](#) method repeatedly. See [How Vertica Divides a Load](#) .

The chunks found by the chunker are then sent to the parser's [process\(\)](#) method for processing in the usual way.

Continuous load

The [ContinuousUDSource](#) , [ContinuousUDFilter](#) , and [ContinuousUDParser](#) classes allow you to write and process data as needed instead of having to iterate through the data. The Python API does not support continuous load.

Each class includes the following functions:

- [initialize\(\)](#) - Invoked before [run\(\)](#) . You can optionally override this function to perform setup and initialization.
- [run\(\)](#) - Processes the data.
- [deinitialize\(\)](#) - Invoked after [run\(\)](#) has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the [setup\(\)](#) , [process\(\)](#) , and [destroy\(\)](#) functions that are inherited from parent classes.

You can use the [yield\(\)](#) function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.

These three classes use associated [ContinuousReader](#) and [ContinuousWriter](#) classes to read input data and write output data.

ContinuousUDSource API (C++)

The [ContinuousUDSource](#) class extends [UDSource](#) and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

ContinuousUDFilter API (C++)

The [ContinuousUDFilter](#) class extends [UDFilter](#) and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

## ContinuousUDParser API

[C++](#)

[Java](#)

The [ContinuousUDParser](#) class extends [UDParser](#) and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

See the API documentation for additional utility methods.

## Buffer classes

Buffer classes are used as handles to the raw data stream for all UDL functions. The C++ and Java APIs use a single [DataBuffer](#) class for both input and output. The Python API has two classes, [InputBuffer](#) and [OutputBuffer](#) .

## DataBuffer API (C++, java)

[C++](#)

[Java](#)

The [DataBuffer](#) class has a pointer to a buffer and size, and an offset indicating how much of the stream has been consumed.

```
/**
 * A contiguous in-memory buffer of char *
 */
struct DataBuffer {
 // Pointer to the start of the buffer
 char * buf;

 // Size of the buffer in bytes
 size_t size;

 // Number of bytes that have been processed by the UDL
 size_t offset;
};
```

## InputBuffer and OutputBuffer APIs (python)

The Python [InputBuffer](#) and [OutputBuffer](#) classes replace the [DataBuffer](#) class in the C++ and Java APIs.

### InputBuffer class

The [InputBuffer](#) class decodes and translates raw data streams depending on the specified encoding. Python natively supports a [wide range of languages and codecs](#) . The [InputBuffer](#) is an argument to the [process\(\)](#) method for both [UDFilters](#) and [UDParsers](#). A user interacts with the UDL's data stream by calling methods of the [InputBuffer](#)

If you do not specify a value for [setEncoding\(\)](#) , Vertica assumes a value of [NONE](#).

```

class InputBuffer:
 def getSize(self):
 ...

 def getOffset(self):
 ...

 def setEncoding(self, encoding):
 """
 Set the encoding of the data contained in the underlying buffer
 """
 pass

 def peek(self, length = None):
 """
 Copy data from the input buffer into Python.
 If no encoding has been specified, returns a Bytes object containing raw data.
 Otherwise, returns data decoded into an object corresponding to the specified encoding
 (for example, 'utf-8' would return a string).
 If length is None, returns all available data.
 If length is not None then the length of the returned object is at most what is requested.
 This method does not advance the buffer offset.
 """
 pass

 def read(self, length = None):
 """
 See peek().
 This method does the same thing as peek(), but it also advances the
 buffer offset by the number of bytes consumed.
 """
 pass

 # Advances the DataBuffer offset by a number of bytes equal to the result
 # of calling "read" with the same arguments.
 def advance(self, length = None):
 """
 Advance the buffer offset by the number of bytes indicated by
 the length and encoding arguments. See peek().
 Returns the new offset.
 """
 pass

```

## OutputBuffer class

The OutputBuffer class encodes and outputs data from Python to Vertica. The OutputBuffer is an argument to the `process()` method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the OutputBuffer to manipulate and encode data.

The `write()` method transfers all data from the Python client to Vertica. The output buffer can accept any size object. If a user writes an object to the OutputBuffer larger than Vertica can immediately process, Vertica stores the overflow. During the next call to `process()`, Vertica checks for leftover data. If there is any, Vertica copies it to the DataBuffer before determining whether it needs to call `process()` from the Python UDL.

If you do not specify a value for `setEncoding()`, Vertica assumes a value of NONE.

```

class OutputBuffer:
def setEncoding(self, encoding):
 """
Specify the encoding of the data which will be written to the underlying buffer
 """
class
def write(self, data):
 """
Transfer bytes from the data object into Vertica.
If an encoding was specified via setEncoding(), the data object will be converted to bytes using the specified encoding.
Otherwise, the data argument is expected to be a Bytes object and is copied to the underlying buffer.
 """
class

```

## Apache Hadoop integration

Apache™ Hadoop™, like Vertica, uses a cluster of nodes for distributed processing. The primary component of interest is HDFS, the Hadoop Distributed File System.

You can use Vertica with HDFS in several ways:

- You can import HDFS data into locally-stored ROS files.
- You can access HDFS data in place using external tables. You can define the tables yourself or get schema information from Hive, a Hadoop component.
- You can use HDFS as a storage location for ROS files.
- You can export data from Vertica to share with other Hadoop components using a Hadoop columnar format. See [File export](#) for more information.

Hadoop file paths are expressed as URLs in the [webhdfs](#) or [hdfs](#) URL scheme. For more about using these schemes, see [HDFS file system](#).

## Hadoop distributions

Vertica can be used with Hadoop distributions from Hortonworks, Cloudera, and MapR. See [Hadoop integrations](#) for the specific versions that are supported.

If you are using Cloudera, you can manage your Vertica cluster using Cloudera Manager. See [Integrating with Cloudera Manager](#).

If you are using MapR, see [Integrating Vertica with the MapR distribution of Hadoop](#).

## WebHDFS requirement

By default, if you use a URL in the [hdfs](#) scheme, Vertica treats it as [webhdfs](#). If you instead use the (deprecated) LibHDFS++ library, you must still have a WebHDFS service available. LibHDFS++ does not support some WebHDFS features, such as encryption zones, wire encryption, or writes, and falls back to WebHDFS when needed.

For some uses, such as Eon Mode communal storage, you must use WebHDFS directly with the [webhdfs](#) scheme.

### Deprecated

Support for LibHDFS++ is deprecated. You can set the [HDFSUseWebHDFS](#) configuration parameter to 0 (disabled) to use LibHDFS++ until it is removed.

In this section

- [Configuring HDFS access](#)
- [Accessing kerberized HDFS data](#)
- [Using HDFS storage locations](#)
- [Using the HCatalog Connector](#)
- [Integrating with Cloudera Manager](#)
- [Integrating Vertica with the MapR distribution of Hadoop](#)
- [Hive primer for Vertica integration](#)

## Cluster layout

Vertica supports two cluster architectures for Hadoop integration. Which architecture you use affects the decisions you make about integration with HDFS. These options might also be limited by license terms.

- You can co-locate Vertica on some or all of your Hadoop nodes. Vertica can then take advantage of data locality.
- You can build a Vertica cluster that is separate from your Hadoop cluster. In this configuration, Vertica can fully use each of its nodes; it does not share resources with Hadoop.

With either architecture, if you are using the `hdfs` scheme to read ORC or Parquet files, you must do some additional configuration. See [Configuring HDFS access](#).

In this section

- [Co-located clusters](#)
- [Configuring Hadoop for co-located clusters](#)
- [Configuring rack locality](#)
- [Separate clusters](#)

### Co-located clusters

With co-located clusters, Vertica is installed on some or all of your Hadoop nodes. The Vertica nodes use a private network in addition to the public network used by all Hadoop nodes, as the following figure shows:

You might choose to place Vertica on all of your Hadoop nodes or only on some of them. If you are using HDFS Storage Locations you should use at least three Vertica nodes, the minimum number for [K-safety in an Enterprise Mode database](#).

Using more Vertica nodes can improve performance because the HDFS data needed by a query is more likely to be local to the node.

You can place Hadoop and Vertica clusters within a single rack, or you can span across many racks and nodes. If you do not co-locate Vertica on every node, you can improve performance by co-locating it on at least one node in each rack. See [Configuring rack locality](#).

Normally, both Hadoop and Vertica use the entire node. Because this configuration uses shared nodes, you must address potential resource contention in your configuration on those nodes. See [Configuring Hadoop for co-located clusters](#) for more information. No changes are needed on Hadoop-only nodes.

### Hardware recommendations

Hadoop clusters frequently do not have identical provisioning requirements or hardware configurations. However, Vertica nodes should be equivalent in size and capability, per the best-practice standards recommended in [Platform and hardware requirements and recommendations](#).

Because Hadoop cluster specifications do not always meet these standards, Vertica recommends the following specifications for Vertica nodes in your Hadoop cluster.

Specifications for...	Recommendation
Processor	For best performance, run: <ul style="list-style-type: none"><li>• Two-socket servers with 8–14 core CPUs, clocked at or above 2.6 GHz for clusters over 10 TB</li><li>• Single-socket servers with 8–12 cores clocked at or above 2.6 GHz for clusters under 10 TB</li></ul>

Memory	<p>Distribute the memory appropriately across all memory channels in the server:</p> <ul style="list-style-type: none"> <li>• <b>Minimum</b> —8 GB of memory per physical CPU core in the server</li> <li>• <b>High-performance applications</b> —12–16 GB of memory per physical core</li> <li>• <b>Type</b> —at least DDR3-1600, preferably DDR3-1866</li> </ul>
Storage	<p>Read/write:</p> <ul style="list-style-type: none"> <li>• <b>Minimum</b> —40 MB/s per physical core of the CPU</li> <li>• <b>For best performance</b> —60–80 MB/s per physical core</li> </ul> <p>Storage post RAID: Each node should have 1–9 TB. For a production setting, Vertica recommends RAID 10. In some cases, RAID 50 is acceptable.</p> <p>Because Vertica performs heavy compression and encoding, SSDs are not required. In most cases, a RAID of more, less-expensive HDDs performs just as well as a RAID of fewer SSDs.</p> <p>If you intend to use RAID 50 for your data partition, you should keep a spare node in every rack, allowing for manual failover of a Vertica node in the case of a drive failure. A Vertica node recovery is faster than a RAID 50 rebuild. Also, be sure to never put more than 10 TB compressed on any node, to keep node recovery times at an acceptable rate.</p>
Network	10 GB networking in almost every case. With the introduction of 10 GB over cat6a (Ethernet), the cost difference is minimal.

## Configuring Hadoop for co-located clusters

If you are co-locating Vertica on any HDFS nodes, there are some additional configuration requirements.

### Hadoop configuration parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

### WebHDFS

Hadoop has two services that can provide web access to HDFS:

- WebHDFS
- httpFS

For Vertica, you must use the WebHDFS service.

### YARN

The YARN service is available in newer releases of Hadoop. It performs resource management for Hadoop clusters. When co-locating Vertica on YARN-managed Hadoop nodes you must make some changes in YARN.

Vertica recommends reserving at least 16GB of memory for Vertica on shared nodes. Reserving more will improve performance. How you do this depends on your Hadoop distribution:

- If you are using Hortonworks, create a "Vertica" node label and assign this to the nodes that are running Vertica.
- If you are using Cloudera, enable and configure static service pools.

Consult the documentation for your Hadoop distribution for details. Alternatively, you can disable YARN on the shared nodes.

### Hadoop balancer

The Hadoop Balancer can redistribute data blocks across HDFS. For many Hadoop services, this feature is useful. However, for Vertica this can reduce performance under some conditions.

If you are using HDFS storage locations, the Hadoop load balancer can move data away from the Vertica nodes that are operating on it, degrading performance. This behavior can also occur when reading ORC or Parquet files if Vertica is not running on all Hadoop nodes. (If you are using separate Vertica and Hadoop clusters, all Hadoop access is over the network, and the performance cost is less noticeable.)

To prevent the undesired movement of data blocks across the HDFS cluster, consider excluding Vertica nodes from rebalancing. See the Hadoop documentation to learn how to do this.

#### Replication factor

By default, HDFS stores three copies of each data block. Vertica is generally set up to store two copies of each data item through K-Safety. Thus, lowering the replication factor to 2 can save space and still provide data protection.

To lower the number of copies HDFS stores, set `HadoopFSReplication`, as explained in [Troubleshooting HDFS storage locations](#).

#### Disk space for Non-HDFS use

You also need to reserve some disk space for non-HDFS use. To reserve disk space using Ambari, set `dfs.datanode.du.reserved` to a value in the `hdfs-site.xml` configuration file.

Setting this parameter preserves space for non-HDFS files that Vertica requires.

#### Configuring rack locality

##### Note

This feature is supported only for reading ORC and Parquet data on co-located clusters. It is only meaningful on Hadoop clusters that span multiple racks.

When possible, when planning a query Vertica automatically uses database nodes that are co-located with the HDFS nodes that contain the data. Moving query execution closer to the data reduces network latency and can improve performance. This behavior, called node locality, requires no additional configuration.

When Vertica is co-located on only a subset of HDFS nodes, sometimes there is no database node that is co-located with the data. However, performance is usually better if a query uses a database node in the same rack. If configured with information about Hadoop rack structure, Vertica attempts to use a database node in the same rack as the data to be queried.

For example, the following diagram illustrates a Hadoop cluster with three racks each containing three data nodes. (Typical production systems have more data nodes per rack.) In each rack, Vertica is co-located on one node.

If you configure rack locality, Vertica uses db01 to query data on dn1, dn2, or dn3, and uses db02 and db03 for data on rack2 and rack3 respectively. Because HDFS replicates data, any given data block can exist in more than one rack. If a data block is replicated on dn2, dn3, and dn6, for example, Vertica uses either db01 or db02 to query it.

Hadoop components are rack-aware, so configuration files describing rack structure already exist in the Hadoop cluster. To use this information in Vertica, configure fault groups that describe this rack structure. Vertica uses fault groups in query planning.

### Configuring fault groups

Vertica uses [Fault groups](#) to describe physical cluster layout. Because your database nodes are co-located on HDFS nodes, Vertica can use the information about the physical layout of the HDFS cluster.

#### Tip

For best results, ensure that each Hadoop rack contains at least one co-located Vertica node.

Hadoop stores its cluster-layout data in a topology mapping file in HADOOP\_CONF\_DIR. On HortonWorks the file is typically named topology\_mappings.data. On Cloudera it is typically named topology.map. Use the data in this file to create an input file for the fault-group script. For more information about the format of this file, see [Creating a fault group input file](#).

Following is an example topology mapping file for the cluster illustrated previously:

```
[network_topology]
dn1.example.com=/rack1
10.20.41.51=/rack1
dn2.example.com=/rack1
10.20.41.52=/rack1
dn3.example.com=/rack1
10.20.41.53=/rack1
dn4.example.com=/rack2
10.20.41.71=/rack2
dn5.example.com=/rack2
10.20.41.72=/rack2
dn6.example.com=/rack2
10.20.41.73=/rack2
dn7.example.com=/rack3
10.20.41.91=/rack3
dn8.example.com=/rack3
10.20.41.92=/rack3
dn9.example.com=/rack3
10.20.41.93=/rack3
```

From this data, you can create the following input file describing the Vertica subset of this cluster:

```
/rack1 /rack2 /rack3
/rack1 = db01
/rack2 = db02
/rack3 = db03
```

This input file tells Vertica that the database node "db01" is on rack1, "db02" is on rack2, and "db03" is on rack3. In creating this file, ignore Hadoop data nodes that are not also Vertica nodes.

After you create the input file, run the fault-group tool:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py dbName input_file > fault_group_ddl.sql
```

The output of this script is a SQL file that creates the fault groups. Execute it following the instructions in [Creating fault groups](#).

You can review the new fault groups with the following statement:

```
=> SELECT member_name,node_address,parent_name FROM fault_groups
INNER JOIN nodes ON member_name=node_name ORDER BY parent_name;
```

member_name	node_address	parent_name
db01	10.20.41.51	/rack1
db02	10.20.41.71	/rack2
db03	10.20.41.91	/rack3

(3 rows)

### Working with multi-level racks

A Hadoop cluster can use multi-level racks. For example, /west/rack-w1, /west/rack-2, and /west/rack-w3 might be served from one data center, while /east/rack-e1, /east/rack-e2, and /east/rack-e3 are served from another. Use the following format for entries in the input file for the fault-group script:

```
/west /east
/west = /rack-w1 /rack-w2 /rack-w3
/east = /rack-e1 /rack-e2 /rack-e3
/rack-w1 = db01
/rack-w2 = db02
/rack-w3 = db03
/rack-e1 = db04
/rack-e2 = db05
/rack-e3 = db06
```

Do not create entries using the full rack path, such as /west/rack-w1.

### Auditing results

To see how much data can be loaded with rack locality, use [EXPLAIN](#) with the query and look for statements like the following in the output:

```
100% of ORC data including co-located data can be loaded with rack locality.
```

### Separate clusters

With separate clusters, a Vertica cluster and a Hadoop cluster share no nodes. You should use a high-bandwidth network connection between the two clusters.

The following figure illustrates the configuration for separate clusters::

### Network

The network is a key performance component of any well-configured cluster. When Vertica stores data to HDFS it writes and reads data across the network.

The layout shown in the figure calls for two networks, and there are benefits to adding a third:

- Database Private Network: Vertica uses a private network for command and control and moving data between nodes in support of its database functions. In some networks, the command and control and passing of data are split across two networks.
- Database/Hadoop Shared Network: Each Vertica node must be able to connect to each Hadoop data node and the NameNode. Hadoop best practices generally require a dedicated network for the Hadoop cluster. This is not a technical requirement, but a dedicated network improves Hadoop performance. Vertica and Hadoop should share the dedicated Hadoop network.
- Optional Client Network: Outside clients may access the clustered networks through a client network. This is not an absolute requirement, but the use of a third network that supports client connections to either Vertica or Hadoop can improve performance. If the configuration does not support a client network, than client connections should use the shared network.

#### Hadoop configuration parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

## Configuring HDFS access

Vertica uses information from the Hadoop cluster configuration to support reading data (COPY or external tables). In Eon Mode, it also uses this information to access communal storage on HDFS. Vertica nodes therefore must have access to certain Hadoop configuration files.

For both co-located and separate clusters that use Kerberos authentication, configure Vertica for Kerberos as explained in [Configure Vertica for Kerberos Authentication](#).

Vertica requires access to the WebHDFS service and ports on all name nodes and data nodes. For more information about WebHDFS ports, see [HDFS Ports in the Cloudera documentation](#).

#### Accessing Hadoop configuration files

Your Vertica nodes need access to certain Hadoop configuration files:

- If Vertica is co-located on HDFS nodes, then those configuration files are already present.
- If Vertica is running on a separate cluster, you must copy the required files to all database nodes. A simple way to do so is to configure your Vertica nodes as Hadoop edge nodes. Client applications run on *edge nodes*; from Hadoop's perspective, Vertica is a client application. You can use Ambari or Cloudera Manager to configure edge nodes. For more information, see the documentation from your Hadoop vendor.

Verify that the value of the HadoopConfDir configuration parameter (see [Hadoop parameters](#)) includes a directory containing the `core-site.xml` and `hdfs-site.xml` files. If you do not set a value, Vertica looks for the files in `/etc/hadoop/conf`. For all Vertica users, the directory is accessed by the Linux user under which the Vertica server process runs.

Vertica uses several properties defined in these configuration files. These properties are listed in [HDFS file system](#).

#### Using a cluster with high availability NameNodes

If your Hadoop cluster uses High Availability (HA) Name Nodes, verify that the `dfs.nameservices` parameter and the individual name nodes are defined in `hdfs-site.xml`.

#### Using more than one Hadoop cluster

In some cases, a Vertica cluster requires access to more than one HDFS cluster. For example, your business might use separate HDFS clusters for separate regions, or you might need data from both test and deployment clusters.

To support multiple clusters, perform the following steps:

1. Copy the configuration files from all HDFS clusters to your database nodes. You can place the copied files in any location readable by Vertica. However, as a best practice, you should place them all in the same directory tree, with one subdirectory per HDFS cluster. The locations must be the same on all database nodes.
2. Set the HadoopConfDir configuration parameter. The value is a colon-separated path containing the directories for all of your HDFS clusters.
3. Use an explicit name node or name service in the URL when creating an external table or copying data. Do not use `hdfs://` because it could be ambiguous. For more information about URLs, see [HDFS file system](#).

Vertica connects directly to a name node or name service; it does not otherwise distinguish among HDFS clusters. Therefore, names of HDFS name nodes and name services must be globally unique.

## Verifying the configuration

Use the [VERIFY\\_HADOOP\\_CONF\\_DIR](#) function to verify that Vertica can find configuration files in HadoopConfDir.

Use the [HDFS\\_CLUSTER\\_CONFIG\\_CHECK](#) function to test access through the `hdfs` scheme.

For more information about testing your configuration, see [Verifying HDFS configuration](#).

## Updating configuration files

If you update the configuration files after starting Vertica, use the following statement to refresh them:

```
=> SELECT CLEAR_HDFS_CACHES();
```

The [CLEAR\\_HDFS\\_CACHES](#) function also flushes information about which name node is active in a High Availability (HA) Hadoop cluster. Therefore, the first request after calling this function is slow, because the initial connection to the name node can take more than 15 seconds.

In this section

- [Verifying HDFS configuration](#)
- [Troubleshooting reads from HDFS](#)

## Verifying HDFS configuration

Use the [EXTERNAL\\_CONFIG\\_CHECK](#) function to test access to HDFS. This function calls several others. If you prefer to test individual components, or if some tests do not apply to your configuration, you can instead call the functions individually. For example, if you are not using the HCatalog Connector then you do not need to call that function. The functions are:

- [KERBEROS\\_CONFIG\\_CHECK](#): tests the Vertica keytab and the user's Kerberos credential.
- [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#): shows the delegation tokens that are in use. This function does not test them.
- [HDFS\\_CLUSTER\\_CONFIG\\_CHECK](#): tests access to the HDFS clusters found in HadoopConfDir, including using Kerberos and impersonation (delegation tokens).
- [HCATALOGCONNECTOR\\_CONFIG\\_CHECK](#): tests HCatalog Connector access to HiveServer2.

To run all tests, call [EXTERNAL\\_CONFIG\\_CHECK](#) with no arguments:

```
=> SELECT EXTERNAL_CONFIG_CHECK();
```

To test only some authorities, nameservices, or Hive schemas, pass a single string argument. The format is a comma-separated list of "key=value" pairs, where keys are "authority", "nameservice", and "schema". The value is passed to all of the sub-functions; see those reference pages for details on how values are interpreted.

The following example tests the configuration of only the nameservice named "ns1":

```
=> SELECT EXTERNAL_CONFIG_CHECK('nameservice=ns1');
```

## Troubleshooting reads from HDFS

You might encounter the following issues when accessing data in HDFS.

### Queries using `[web]hdfs://` show unexpected results

If you are using the `///` shorthand to query external tables and see unexpected results, such as production data in your test cluster, verify that [HadoopConfDir](#) is set to the value you expect. The `HadoopConfDir` configuration parameter defines a path to search for the Hadoop configuration files that Vertica needs to resolve file locations. The `HadoopConfDir` parameter can be set at the session level, overriding the permanent value set in the database.

To debug problems with `///` URLs, try replacing the URLs with ones that use an explicit nameservice or name node. If the explicit URL works, then the problem is with the resolution of the shorthand. If the explicit URL also does not work as expected, then the problem is elsewhere (such as your nameservice).

### Queries take a long time to run when using HA

The High Availability Name Node feature in HDFS allows a name node to fail over to a standby name node. The `dfs.client.failover.max.attempts` configuration parameter (in `hdfs-site.xml`) specifies how many attempts to make when failing over. Vertica uses a default value of 4 if this parameter is not set. After reaching the maximum number of failover attempts, Vertica concludes that the HDFS cluster is unavailable and aborts the operation.

Vertica uses the `dfs.client.failover.sleep.base.millis` and `dfs.client.failover.sleep.max.millis` parameters to decide how long to wait between retries. Typical ranges are 500 milliseconds to 15 seconds, with longer waits for successive retries.

A second parameter, `ipc.client.connect.retry.interval`, specifies the time to wait between attempts, with typical values being 10 to 20 seconds.

Cloudera and Hortonworks both provide tools to automatically generate configuration files. These tools can set the maximum number of failover attempts to a much higher number (50 or 100). If the HDFS cluster is unavailable (all name nodes are unreachable), Vertica can appear to hang for an extended period (minutes to hours) while trying to connect.

Failover attempts are logged in the [QUERY\\_EVENTS](#) system table. The following example shows how to query this table to find these events:

```
=> SELECT event_category, event_type, event_description, operator_name,
event_details, count(event_type) AS count
FROM query_events
WHERE event_type ilike 'WEBHDFS FAILOVER RETRY'
GROUP BY event_category, event_type, event_description, operator_name, event_details;
-[RECORD 1]-----+-----
event_category | EXECUTION
event_type | WEBHDFS FAILOVER RETRY
event_description | WebHDFS Namenode failover and retry.
operator_name | WebHDFS FileSystem
event_details | WebHDFS request failed on ns
count | 4
```

You can either wait for Vertica to complete or abort the connection, or set the `dfs.client.failover.max.attempts` parameter to a lower value.

#### WebHDFS error when using LibHDFS++

When creating an external table or loading data and using the `hdfs` scheme, you might see errors from WebHDFS failures. Such errors indicate that Vertica was not able to use the `hdfs` scheme and fell back to `webhdfs`, but that the WebHDFS configuration is incorrect.

First verify the value of the [HadoopConfDir](#) configuration parameter, which can be set at the session level. Then verify that the HDFS configuration files found there have the correct WebHDFS configuration for your Hadoop cluster. See [Configuring HDFS access](#) for information about use of these files. See your Hadoop documentation for information about WebHDFS configuration.

Vertica places too much load on the name node (LibHDFS++)

Large HDFS clusters can sometimes experience heavy load on the name node when clients, including Vertica, need to locate data. If your name node is sensitive to this load and if you are using LibHDFS++, you can instruct Vertica to distribute metadata about block locations to its nodes so that they do not have to contact the name node as often. Distributing this metadata can degrade database performance somewhat in deployments where the name node isn't contended. This performance effect is because the data must be serialized and distributed.

If protecting your name node from load is more important than query performance, set the [EnableHDFSBlockInfoCache](#) configuration parameter to 1 (true). Usually this applies to large HDFS clusters where name node contention is already an issue.

This setting applies to access through LibHDFS++ (`hdfs` scheme). Sometimes LibHDFS++ falls back to WebHDFS, which does not use this setting. If you have enabled this setting and you are still seeing high traffic on your name node from Vertica, check the [QUERY\\_EVENTS](#) system table for `LibHDFS++ UNSUPPORTED OPERATION` events.

#### Kerberos authentication errors

Kerberos authentication can fail even though a ticket is valid if Hadoop expires tickets frequently. It can also fail due to clock skew between Hadoop and Vertica nodes. For details, see [Troubleshooting Kerberos authentication](#).

## Accessing kerberized HDFS data

If your Hortonworks or Cloudera Hadoop cluster uses Kerberos authentication to restrict access to HDFS, Vertica must be granted access. If you use Kerberos authentication for your Vertica database, and database users have HDFS access, then you can configure Vertica to use the same principals to authenticate. However, not all Hadoop administrators want to grant access to all database users, preferring to manage access in other ways. In addition, not all Vertica databases use Kerberos.

Vertica provides the following options for accessing Kerberized Hadoop clusters:

- Using Vertica Kerberos principals.
- Using Hadoop proxy users combined with Vertica users.
- Using a user-specified delegation token which grants access to HDFS. Delegation tokens are issued by the Hadoop cluster.

Proxy users and delegation tokens both use a session parameter to manage identities. Vertica need not be Kerberized when using either of these methods.

Vertica does not support Kerberos for MapR.

To test your Kerberos configuration, see [Verifying HDFS configuration](#).

In this section

- [Using Kerberos with Vertica](#)
- [Proxy users and delegation tokens](#)
- [Token expiration](#)

## Using Kerberos with Vertica

If you use Kerberos for your Vertica cluster and your principals have access to HDFS, then you can configure Vertica to use the same credentials for HDFS.

Vertica authenticates with Hadoop in two ways that require different configurations:

- **User Authentication** —On behalf of the user, by passing along the user's existing Kerberos credentials. This method is also called user impersonation. Actions performed on behalf of particular users, like executing queries, generally use user authentication.
- **Vertica Authentication** —On behalf of system processes that access ROS data or the catalog, by using a special Kerberos credential stored in a keytab file.

### Note

Vertica and Hadoop must use the same Kerberos server or servers (KDCs).

Vertica can interact with more than one Kerberos realm. To configure multiple realms, see [Multi-realm Support](#).

Vertica attempts to automatically refresh Hadoop tokens before they expire. See [Token expiration](#).

### User authentication

To use Vertica with Kerberos and Hadoop, the client user first authenticates with one of the Kerberos servers (Key Distribution Center, or KDC) being used by the Hadoop cluster. A user might run `kinit` or sign in to Active Directory, for example.

A user who authenticates to a Kerberos server receives a Kerberos ticket. At the beginning of a client session, Vertica automatically retrieves this ticket. Vertica then uses this ticket to get a Hadoop token, which Hadoop uses to grant access. Vertica uses this token to access HDFS, such as when executing a query on behalf of the user. When the token expires, Vertica automatically renews it, also renewing the Kerberos ticket if necessary.

The user must have been granted permission to access the relevant files in HDFS. This permission is checked the first time Vertica reads HDFS data.

Vertica can use multiple KDCs serving multiple Kerberos realms, if proper cross-realm trust has been set up between realms.

### Vertica authentication

Automatic processes, such as the Tuple Mover or the processes that access Eon Mode communal storage, do not log in the way users do. Instead, Vertica uses a special identity (principal) stored in a keytab file on every database node. (This approach is also used for Vertica clusters that use Kerberos but do not use Hadoop.) After you configure the keytab file, Vertica uses the principal residing there to automatically obtain and maintain a Kerberos ticket, much as in the client scenario. In this case, the client does not interact with Kerberos.

Each Vertica node uses its own principal; it is common to incorporate the name of the node into the principal name. You can either create one keytab per node, containing only that node's principal, or you can create a single keytab containing all the principals and distribute the file to all nodes. Either way, the node uses its principal to get a Kerberos ticket and then uses that ticket to get a Hadoop token.

When creating HDFS storage locations Vertica uses the principal in the keytab file, not the principal of the user issuing the CREATE LOCATION statement. The HCatalog Connector sometimes uses the principal in the keytab file, depending on how Hive authenticates users.

### Configuring users and the keytab file

If you have not already configured Kerberos authentication for Vertica, follow the instructions in [Configure Vertica for Kerberos authentication](#). Of particular importance for Hadoop integration:

1. Create one Kerberos principal per node.
2. Place the keytab files in the same location on each database node and set configuration parameter `KerberosKeytabFile` to that location.
3. Set `KerberosServiceName` to the name of the principal. (See [Inform Vertica about the Kerberos principal](#).)

If you are using the HCatalog Connector, follow the additional steps in [Configuring security](#) in the HCatalog Connector documentation.

If you are using HDFS storage locations, give all node principals read and write permission to the HDFS directory you will use as a storage location.

## Proxy users and delegation tokens

An alternative to granting HDFS access to individual Vertica users is to use delegation tokens, either directly or with a proxy user. In this configuration, Vertica accesses HDFS on behalf of some other (Hadoop) user. The Hadoop users need not be Vertica users at all.

In Vertica, you can either specify the name of the Hadoop user to act on behalf of (doAs), or you can directly use a Kerberos delegation token that you obtain from HDFS (Bring Your Own Delegation Token). In the doAs case, Vertica obtains a delegation token for that user, so both approaches ultimately use delegation tokens to access files in HDFS.

Use the [HadoopImpersonationConfig](#) session parameter to specify a user or delegation token to use for HDFS access. Each session can use a different user and can use either doAs or a delegation token. The value of HadoopImpersonationConfig is a set of JSON objects.

To use delegation tokens of either type (more specifically, when HadoopImpersonationConfig is set), you must access HDFS through WebHDFS.

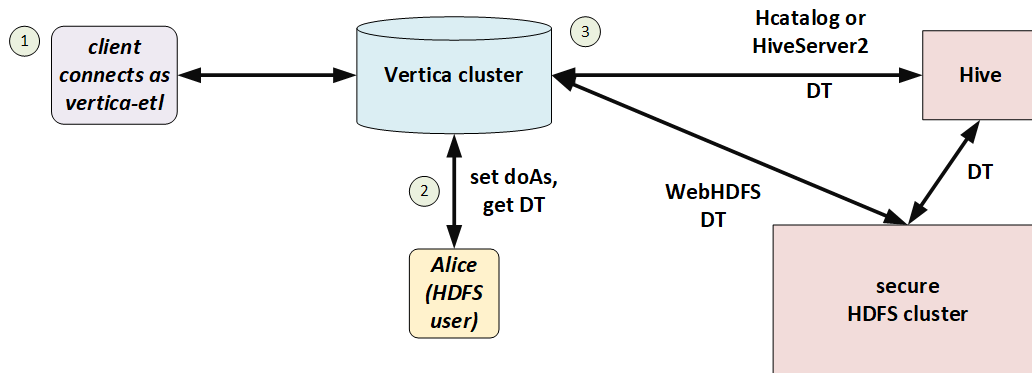

In this section

- [User impersonation \(doAs\)](#)
- [Bring your own delegation token](#)
- [Getting a HiveServer2 delegation token](#)
- [HadoopImpersonationConfig format](#)

## User impersonation (doAs)

You can use user impersonation to access data in an HDFS cluster from Vertica. This approach is called "doAs" (for "do as") because Vertica uses a single proxy user on behalf of another (Hadoop) user. The impersonated Hadoop user does not need to also be a Vertica user.

In the following illustration, Alice is a Hadoop user but not a Vertica user. She connects to Vertica as the proxy user, vertica-etl. In her session, Vertica obtains a delegation token (DT) on behalf of the doAs user (Alice), and uses that delegation token to access HDFS.

You can use doAs with or without Kerberos, so long as HDFS and Vertica match. If HDFS uses Kerberos then Vertica must too.

## User configuration

The Hadoop administrator must create a [proxy user](#) and allow it to access HDFS on behalf of other users. Set values in core-site.xml as in the following example:

```
<name>hadoop.proxyuser.vertica-etl.users</name>
<value>*</value>
<name>hadoop.proxyuser.vertica-etl.hosts</name>
<value>*</value>
```

In Vertica, create a corresponding user.

## Session configuration

To make requests on behalf of a Hadoop user, first set the [HadoopImpersonationConfig](#) session parameter to specify the user and HDFS cluster. Vertica will access HDFS as that user until the session ends or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies an HDFS cluster and a Hadoop user. For the cluster, you can specify either a name service or an individual name node. If you are using HA name node, then you must either use a name service or specify all name nodes. [HadoopImpersonationConfig format](#) describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "vertica-etl" is a Vertica user.

```
$ vsql -U vertica-etl

=> ALTER SESSION SET
 HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"stephanie"}]';
=> COPY nation FROM 'webhdfs:///user/stephanie/nation.dat';

=> ALTER SESSION SET
 HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"bob"}, {"authority":"hadoop2:50070", "doAs":"rob"}]';
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

Vertica uses Hadoop delegation tokens, obtained from the name node, to impersonate Hadoop users. In a long-running session, a token could expire. Vertica attempts to renew tokens automatically; see [Token expiration](#).

### Testing the configuration

You can use the [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#) function to test your HDFS delegation tokens and [HCATALOGCONNECTOR\\_CONFIG\\_CHECK](#) to test your HCatalog Connector delegation token.

### Bring your own delegation token

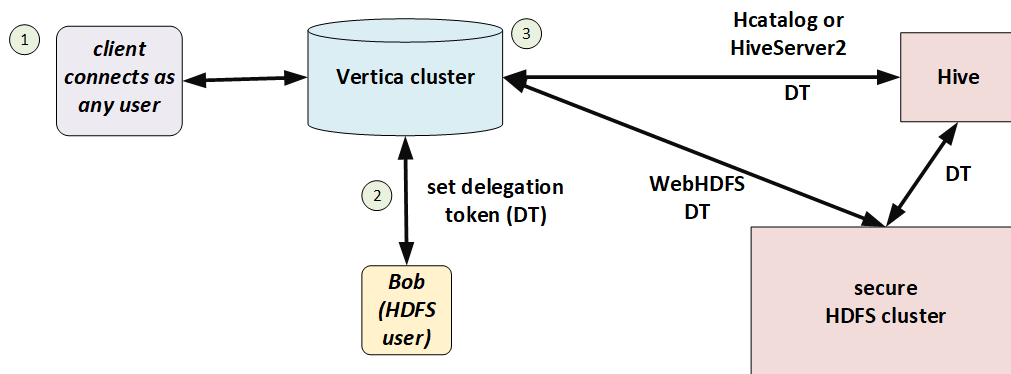

Instead of creating a proxy user and giving it access to HDFS for use with doAs, you can give Vertica a Hadoop delegation token to use. You must obtain this delegation token from the Hadoop name node. In this model, security is handled entirely on the Hadoop side, with Vertica just passing along a token. Vertica may or may not be Kerberized.

A typical workflow is:

- In an ETL front end, a user submits a query.
- The ETL system uses authentication and authorization services to verify that the user has sufficient permission to run the query.
- The ETL system requests a delegation token for the user from the name node.
- The ETL system makes a client connection to Vertica, sets the delegation token for the session, and runs the query.

When using a delegation token, clients can connect as any Vertica user. No proxy user is required.

In the following illustration, Bob has a Hadoop-issued delegation token. He connects to Vertica and Vertica uses that delegation token to access files in HDFS.

### Session configuration

Set the [HadoopImpersonationConfig](#) session parameter to specify the delegation token and HDFS cluster. Vertica will access HDFS using that delegation token until the session ends, the token expires, or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies a delegation token ("token") in WebHDFS format and an HDFS name service or name node. [HadoopImpersonationConfig format](#) describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "dbuser1" is a Vertica user with no special privileges.

```
$ vsql -U dbuser1
```

```
=> ALTER SESSION SET
```

```
 HadoopImpersonationConfig = [{"authority":"hadoop1:50070","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDX.JgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUIJREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
```

```
=> COPY nation FROM 'webhdfs:///user/stephanie/nation.dat';
```

```
=> ALTER SESSION SET
```

```
 HadoopImpersonationConfig = [{"authority":"hadoop1:50070","token":"HgADdG9tA3RvbQCKAWDX.JgAoigFg-
zKEKl4gal4BmhRoOUpq_jPxrVhZ1NSMnodAQnhUthJXRUIJREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
```

```
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

You can use the [WebHDFS REST API](#) to get delegation tokens:

```
$ curl -s --no-proxy "" --negotiate -u: -X GET "http://hadoop1:50070/webhdfs/v1/?op=GETDELEGATIONTOKEN"
```

Vertica does not, and cannot, renew delegation tokens when they expire. You must either keep sessions shorter than token lifetime or implement a renewal scheme.

### Delegation tokens and the HCatalog Connector

HiveServer2 uses a different format for delegation tokens. To use the HCatalog Connector, therefore, you must set two delegation tokens, one as usual (authority) and one for HiveServer2 (schema). The HCatalog Connector uses the schema token to access metadata and the authority token to access data. The schema name is the same Hive schema you specified in CREATE HCATALOG SCHEMA. The following example shows how to use these two delegation tokens.

```
$ vsql -U dbuser1
```

```
-- set delegation token for user and HiveServer2
```

```
=> ALTER SESSION SET
```

```
 HadoopImpersonationConfig=[
 {"nameservice":"hadoopNS","token":"JQAHCmVsZWFzZQdyZWxIYXNlAloBYVJKrYsKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjU0OjgwMjA"}],
```

```
 {"schema":"access","token":"UwAHcmVsZWFzZQdyZWxIYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSVEIDQUNPUIAuQ09NigFhU
kmyT0oBYXZWNk4BjgETFKN2xPURn19Yq9tf-0nekoD51TZvFUhJVkVfREVMRUdBEIPI9UT0tFThZoaXZlc2VydMvYmMkNsaWVudFRva2Vu"}];
```

```
-- uses HiveServer2 token to get metadata
```

```
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';
```

```
-- uses both tokens
```

```
=> SELECT * FROM access.t1;
```

```
--uses only HiveServer2 token
```

```
=> SELECT * FROM hcatalog_tables;
```

HiveServer2 does not provide a REST API for delegation tokens like WebHDFS does. See [Getting a HiveServer2 delegation token](#) for some tips.

### Testing the configuration

You can use the [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#) function to test your HDFS delegation tokens and [HCATALOGCONNECTOR\\_CONFIG\\_CHECK](#) to test your HCatalog Connector delegation token.

### Getting a HiveServer2 delegation token

To access Hive metadata using HiveServer2, you need a special delegation token. (See [Bring your own delegation token](#).) HiveServer2 does not provide an easy way to get this token, unlike the REST API that grants HDFS (data) delegation tokens.

The following utility code shows a way to get this token. You will need to modify this code for your own cluster; in particular, change the value of the `connectURL` static.

```
import java.io.FileWriter;
import java.io.PrintStream;
import java.io.PrintWriter;
import java.io.StringWriter;
.....
```

```

import java.io.Writer;
import java.security.PrivilegedExceptionAction;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.hive.shims.Utils;
import org.apache.hadoop.security.UserGroupInformation;
import org.apache.hive.jdbc.HiveConnection;
import org.json.simple.JSONArray;
import org.json.simple.JSONObject;

public class JDBCtest {

### HadoopImpersonationConfig format

The value of the [HadoopImpersonationConfig](#) session parameter is a set of one or more JSON objects. Each object describes one doAs user or delegation token for one Hadoop destination. You must use WebHDFS, not LibHDFS++, to use impersonation.

### Syntax

```
[{ ("doAs" | "token"): value,
 ("nameservice" | "authority" | "schema"): value } [...]
```

### Properties

<b>doAs</b>	The name of a Hadoop user to impersonate.
<b>token</b>	A delegation token to use for HDFS access.
<b>nameservice</b>	A Hadoop name service. All access to this name service uses the doAs user or delegation token.
<b>authority</b>	A name node authority. All access to this authority uses the doAs user or delegation token. If the name node fails over to another name node, the doAs user or delegation token does <i>not</i> automatically apply to the failover name node. If you are using HA name node, use <b>nameservice</b> instead of <b>authority</b> or include objects for every name node.
<b>schema</b>	A Hive schema, for use with the HCatalog Connector. Vertica uses this object's doAs user or token to access Hive metadata only. For data access you must also specify a name service or authority object, just like for all other data access.

### Examples

In the following example of doAs, Bob is a Hadoop user and vertica-etl is a Kerberized proxy user.

```
$ kinit vertica-etl -kt /home/dbadmin/vertica-etl.keytab
$ vsql -U vertica-etl
=> ALTER SESSION SET
 HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"Bob"}]';
=> COPY nation FROM 'webhdfs:///user/bob/nation.dat';
```

In the following example, the current Vertica user (it doesn't matter who that is) uses a Hadoop delegation token. This token belongs to Alice, but you never specify the user name here. Instead, you use it to get the delegation token from Hadoop.

```
$ vsql -U dbuser1
=> ALTER SESSION SET
 HadoopImpersonationConfig = [{"nameservice":"hadoopNS","token":"JAAGZGJldGwxBmRiZXRMsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUIJIREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}];
=> COPY nation FROM 'webhdfs://user/alice/nation.dat';
```

In the following example, "authority" specifies the (single) name node on a Hadoop cluster that does not use high availability.

```
$ vsql -U dbuser1
=> ALTER SESSION SET
 HadoopImpersonationConfig = [{"authority":"hadoop1:50070", "doAs":"Stephanie"}];
=> COPY nation FROM 'webhdfs://hadoop1:50070/user/stephanie/nation.dat';
```

To access data in Hive you need to specify two delegation tokens. The first, for a name service or authority, is for data access as usual. The second is for the HiveServer2 metadata for the schema. HiveServer2 requires a delegation token in WebHDFS format. The schema name is the Hive schema you specify with CREATE HCATALOG SCHEMA.

```
$ vsql -U dbuser1
-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
 HadoopImpersonationConfig=[
 {"nameservice":"hadoopNS","token":"JQAHcmVsZWFzZQdyZWxlYXNlIoBYVJKrYsKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjU0OjgwMjA"},
{"schema":"access","token":"UwAHcmVsZWFzZQdyZWxlYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSVEIDQUNPUIAuQ09NigFhU
kmyTooBYXZWNk4BjgETFKN2xPURn19Yq9tf-0nekoD51TZvFUhJVkVfREVMRUdBEIPTI9UT0tFTThZoaXZlc2VydmdyMkNsaWVudFRva2Vu"}];
-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';
-- uses both tokens
=> SELECT * FROM access.t1;
--uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;
```

Each object in the HadoopImpersonationConfig collection specifies one connection to one Hadoop cluster. You can add as many connections as you like, including to more than one Hadoop cluster. The following example shows delegation tokens for two different Hadoop clusters. Vertica uses the correct token for each cluster when connecting.

```
$ vsql -U dbuser1
=> ALTER SESSION SET
 HadoopImpersonationConfig = [
 {"nameservice":"productionNS","token":"JAAGZGJldGwxBmRiZXRMsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUIJIREZTIGRlBGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"},
 {"nameservice":"testNS", "token":"HQAHCmVsZWFzZQdyZWxlYXNlIoBYVJKrYsKAWF2VzGEjgmzj_IUCIrI9b8Dqu6awFTHk5nC-
fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjU0OjgwMjA"}];
=> COPY clicks FROM 'webhdfs://productionNS/data/clickstream.dat';
=> COPY testclicks FROM 'webhdfs://testNS/data/clickstream.dat';
```

Token expiration

Vertica uses Hadoop tokens when using Kerberos tickets ( [Using Kerberos with Vertica](#) ) or doAs ( [User impersonation \(doAs\)](#) ). Vertica attempts to automatically refresh Hadoop tokens before they expire, but you can also set a minimum refresh frequency if you prefer. Use the `HadoopFSTokenRefreshFrequency` configuration parameter to specify the frequency in seconds:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

If the current age of the token is greater than the value specified in this parameter, Vertica refreshes the token before accessing data stored in HDFS.

Vertica does not refresh delegation tokens ( [Bring your own delegation token](#) ).

## Using HDFS storage locations

Vertica stores data in its native format, ROS, in storage locations. You can place storage locations on the local Linux file system or in HDFS. If you place storage locations on HDFS, you must perform additional configuration in HDFS to be able to manage them. These are in addition to the requirements in Vertica for [managing storage locations](#) and [backup/restore](#) .

If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

In this section

- [Hadoop configuration for backup and restore](#)
- [Removing HDFS storage locations](#)

### Hadoop configuration for backup and restore

If your Vertica cluster uses storage locations on HDFS, and you want to be able to back up and restore those storage locations using `vbr` , you must enable snapshotting in HDFS.

The Vertica backup script uses HDFS's snapshotting feature to create a backup of HDFS storage locations. A directory must allow snapshotting before HDFS can take a snapshot. Only a Hadoop superuser can enable snapshotting on a directory. Vertica can enable snapshotting automatically if the database administrator is also a Hadoop superuser.

If HDFS is unsecured, the following instructions apply to the database administrator account, usually `dbadmin` . If HDFS uses Kerberos security, the following instructions apply to the principal stored in the Vertica keytab file, usually `vertica` . The instructions below use the term "database account" to refer to this user.

We recommend that you make the database administrator or principal a Hadoop superuser. If you are not able to do so, you must enable snapshotting on the directory before configuring it for use by Vertica.

The steps you need to take to make the Vertica database administrator account a superuser depend on the distribution of Hadoop you are using. Consult your Hadoop distribution's documentation for details.

### Manually enabling snapshotting for a directory

If you cannot grant superuser status to the database account, you can instead enable snapshotting of each directory manually. Use the following command:

```
$ hdfs dfsadmin -allowSnapshot path
```

Issue this command for each directory on each node. Remember to do this each time you add a new node to your HDFS cluster.

Nested snapshottable directories are not allowed, so you cannot enable snapshotting for a parent directory to automatically enable it for child directories. You must enable it for each individual directory.

### Additional requirements for Kerberos

If HDFS uses Kerberos, then in addition to granting the keytab principal access, you must give Vertica access to certain Hadoop configuration files. See [Configuring Kerberos](#) .

### Testing the database account's ability to make HDFS directories snapshottable

After making the database account a Hadoop superuser, verify that the account can set directories snapshottable:

1. Log into the Hadoop cluster as the database account (`dbadmin` by default).
2. Determine a location in HDFS where the database administrator can create a directory. The `/tmp` directory is usually available. Create a test HDFS directory using the command:

```
$ hdfs dfs -mkdir /path/testdir
```

3. Make the test directory snapshottable using the command:

```
$ hdfs dfsadmin -allowSnapshot /path/testdir
```

The following example demonstrates creating an HDFS directory and making it snapshottable:

```
$ hdfs dfs -mkdir /tmp/snaptest
$ hdfs dfsadmin -allowSnapshot /tmp/snaptest
Allowing snapshot on /tmp/snaptest succeeded
```

## Removing HDFS storage locations

The steps to remove an HDFS storage location are similar to standard storage locations:

1. Remove any existing data from the HDFS storage location by using [SET\\_OBJECT\\_STORAGE\\_POLICY](#) to change each object's storage location. Alternatively, you can use [CLEAR\\_OBJECT\\_STORAGE\\_POLICY](#). Because the Tuple Mover runs infrequently, set the `enforce-storage-move` parameter to `true` to make the change immediately.
2. Retire the location on each host that has the storage location defined using [RETIRE\\_LOCATION](#). Set `enforce-storage-move` to `true`.
3. Drop the location on each node using [DROP\\_LOCATION](#).
4. Optionally remove the snapshots and files from the HDFS directory for the storage location.
5. Perform a full database backup.

For more information about changing storage policies, changing usage, retiring locations, and dropping locations, see [Managing storage locations](#).

### Important

If you have backed up the data in the HDFS storage location you are removing, you must perform a full database backup after you remove the location. If you do not and restore the database to a backup made before you removed the location, the location's data is restored.

## Removing storage location files from HDFS

Dropping an HDFS storage location does not automatically clean the HDFS directory that stored the location's files. Any snapshots of the data files created when backing up the location are also not deleted. These files consume disk space on HDFS and also prevent the directory from being reused as an HDFS storage location. Vertica cannot create a storage location in a directory that contains existing files or subdirectories.

You must log into the Hadoop cluster to delete the files from HDFS. An alternative is to use some other HDFS file management tool.

## Removing backup snapshots

HDFS returns an error if you attempt to remove a directory that has snapshots:

```
$ hdfs dfs -rm -r -f -skipTrash /user/dbadmin/v_vmart_node0001
rm: The directory /user/dbadmin/v_vmart_node0001 cannot be deleted since
/user/dbadmin/v_vmart_node0001 is snapshottable and already has snapshots
```

The Vertica backup script creates snapshots of HDFS storage locations as part of the backup process. If you made backups of your HDFS storage location, you must delete the snapshots before removing the directories.

HDFS stores snapshots in a subdirectory named `.snapshot`. You can list the snapshots in the directory using the standard HDFS `ls` command:

```
$ hdfs dfs -ls /user/dbadmin/v_vmart_node0001/.snapshot
Found 1 items
drwxrwx--- - dbadmin supergroup 0 2014-09-02 10:13 /user/dbadmin/v_vmart_node0001/.snapshot/s20140902-101358.629
```

To remove snapshots, use the command:

```
$ hdfs dfs -removeSnapshot directory snapshotname
```

The following example demonstrates the command to delete the snapshot shown in the previous example:

```
$ hdfs dfs -deleteSnapshot /user/dbadmin/v_vmart_node0001 s20140902-101358.629
```

You must delete each snapshot from the directory for each host in the cluster. After you have deleted the snapshots, you can delete the directories in the storage location.

### Important

Each snapshot's name is based on a timestamp down to the millisecond. Nodes independently create their own snapshots. They do not synchronize snapshot creation, so their snapshot names differ. You must list each node's snapshot directory to learn the names of the snapshots it contains.

See Apache's [HDFS Snapshot documentation](#) for more information about managing and removing snapshots.

Removing the storage location directories

You can remove the directories that held the storage location's data by either of the following methods:

- Use an HDFS file manager to delete directories. See your Hadoop distribution's documentation to determine if it provides a file manager.
- Log into the Hadoop Name Node using the database administrator's account and use HDFS's `rmr` command to delete the directories. See Apache's [File System Shell Guide](#) for more information.

The following example uses the HDFS `rmr` command from the Linux command line to delete the directories left behind in the HDFS storage location directory `/user/dbadmin`. It uses the `-skipTrash` flag to force the immediate deletion of the files:

```
$ hdfs dfs -ls /user/dbadmin
Found 3 items
drwxrwx--- - dbadmin supergroup 0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0001
drwxrwx--- - dbadmin supergroup 0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0002
drwxrwx--- - dbadmin supergroup 0 2014-08-29 15:11 /user/dbadmin/v_vmart_node0003

$ hdfs dfs -rmr -skipTrash /user/dbadmin/*
Deleted /user/dbadmin/v_vmart_node0001
Deleted /user/dbadmin/v_vmart_node0002
Deleted /user/dbadmin/v_vmart_node0003
```

## Using the HCatalog Connector

The Vertica HCatalog Connector lets you access data stored in Apache's Hive data warehouse software the same way you access it within a native Vertica table.

If your files are in the Optimized Columnar Row (ORC) or Parquet format and do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. See [ORC](#) and [PARQUET](#) for more information about these readers.

The HCatalog Connector performs predicate pushdown to improve query performance. Instead of reading all data across the network to evaluate a query, the HCatalog Connector moves the evaluation of predicates closer to the data. Predicate pushdown applies to Hive partition pruning, ORC stripe pruning, and Parquet row-group pruning. The HCatalog Connector supports predicate pushdown for the following predicates: `>`, `>=`, `=`, `<>`, `<=`, `<`.

- [Using nonstandard SerDes](#)
- [Troubleshooting HCatalog Connector problems](#)

### Overview

There are several Hadoop components that you need to understand to use the HCatalog connector:

- Apache Hive lets you query data stored in a Hadoop Distributed File System (HDFS) the same way you query data stored in a relational database. Behind the scenes, Hive uses a set of serializer and deserializer (SerDe) classes to extract data from files stored in HDFS and break it into columns and rows. Each SerDe handles data files in a specific format. For example, one SerDe extracts data from comma-separated data files while another interprets data stored in JSON format.
- Apache HCatalog is a component of the Hadoop ecosystem that makes Hive's metadata available to other Hadoop components (such as Pig).
- HiveServer2 makes HCatalog and Hive data available via JDBC. Through it, a client can make requests to retrieve data stored in Hive, as well as information about the Hive schema. HiveServer2 can use authorization services (Sentry or Ranger). HiveServer2 can use Hive LLAP (Live Long And Process).

The Vertica HCatalog Connector lets you transparently access data that is available through HiveServer2. You use the connector to define a schema in Vertica that corresponds to a Hive database or schema. When you query data within this schema, the HCatalog Connector transparently extracts and formats the data from Hadoop into tabular data. Vertica supports authorization services and Hive LLAP.

#### Note

You can use the WebHCat service instead of HiveServer2, but performance is usually better with HiveServer2. Support for WebHCat is deprecated. To use WebHCat, set the `HCatalogConnectorUseHiveServer2` configuration parameter to 0. See [Hadoop parameters](#). WebHCat does not support authorization services.

### HCatalog connection features

The HCatalog Connector lets you query data stored in Hive using the Vertica native SQL syntax. Some of its main features are:

- The HCatalog Connector always reflects the current state of data stored in Hive.
- The HCatalog Connector uses the parallel nature of both Vertica and Hadoop to process Hive data. The result is that querying data through the HCatalog Connector is often faster than querying the data directly through Hive.
- Because Vertica performs the extraction and parsing of data, the HCatalog Connector does not significantly increase the load on your Hadoop cluster.
- The data you query through the HCatalog Connector can be used as if it were native Vertica data. For example, you can execute a query that joins data from a table in an HCatalog schema with a native table.

### HCatalog Connector considerations

There are a few things to keep in mind when using the HCatalog Connector:

- Hive's data is stored in flat files in a distributed file system, requiring it to be read and deserialized each time it is queried. This deserialization causes Hive performance to be much slower than that of Vertica. The HCatalog Connector has to perform the same process as Hive to read the data. Therefore, querying data stored in Hive using the HCatalog Connector is much slower than querying a native Vertica table. If you need to perform extensive analysis on data stored in Hive, you should consider loading it into Vertica. Vertica optimization often makes querying data through the HCatalog Connector faster than directly querying it through Hive.
- If Hive uses Kerberos security, the HCatalog Connector uses the querying user's credentials in queries by default. If Hive uses Sentry or Ranger to enforce security, then you must either disable this behavior in Vertica by setting `EnableHCatImpersonation` to 0 or grant users access to the underlying data in HDFS. (Sentry supports ACL synchronization to automatically grant access.) Alternatively, you can specify delegation tokens for data and metadata access. See [Configuring security](#).
- Hive supports complex data types such as lists, maps, and structs that Vertica does not support. Columns containing these data types are converted to a JSON representation of the data type and stored as a VARCHAR. See [Data type conversions from Hive to Vertica](#).

#### Note

The HCatalog Connector is read-only. It cannot insert data into Hive.

### How the HCatalog Connector works

When planning a query that accesses data from a Hive table, the Vertica HCatalog Connector on the initiator node contacts HiveServer2 (or WebHCat) in your Hadoop cluster to determine if the table exists. If it does, the connector retrieves the table's metadata from the metastore database so the query planning can continue. When the query executes, all nodes in the Vertica cluster directly retrieve the data necessary for completing the query from HDFS. They then use the Hive SerDe classes to extract the data so the query can execute. When accessing data in ORC or Parquet format, the HCatalog Connector uses Vertica's internal readers for these formats instead of the Hive SerDe classes.

This approach takes advantage of the parallel nature of both Vertica and Hadoop. In addition, by performing the retrieval and extraction of data directly, the HCatalog Connector reduces the impact of the query on the Hadoop cluster.

For files in the Optimized Columnar Row (ORC) or Parquet format that do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. You can direct these readers to access custom Hive partition locations if Hive used them when writing the data. By default these extra checks are turned off to improve performance.

## HCatalog Connector requirements

Before you can use the HCatalog Connector, both your Vertica and Hadoop installations must meet the following requirements.

### Vertica requirements

All of the nodes in your cluster must have a Java Virtual Machine (JVM) installed. You must use the same Java version that the Hadoop cluster uses. See [Installing the Java Runtime on Your Vertica Cluster](#).

You must also add certain libraries distributed with Hadoop and Hive to your Vertica installation directory. See [Configuring Vertica for HCatalog](#).

### Hadoop requirements

Your Hadoop cluster must meet several requirements to operate correctly with the Vertica Connector for HCatalog:

- It must have Hive, HiveServer2, and HCatalog installed and running. See Apache's [HCatalog](#) page for more information.
- The HiveServer2 server and all of the HDFS nodes that store HCatalog data must be directly accessible from all of the hosts in your Vertica database. Verify that any firewall separating the Hadoop cluster and the Vertica cluster will pass HiveServer2, metastore database, and HDFS traffic.
- The data that you want to query must be in an internal or external Hive table.
- If a table you want to query uses a non-standard SerDe, you must install the SerDe's classes on your Vertica cluster before you can query the data. See [Using nonstandard SerDes](#).

## Installing the Java runtime on your Vertica cluster

The HCatalog Connector requires a 64-bit Java Virtual Machine (JVM). The JVM must support Java 6 or later, and must be the same version as the one installed on your Hadoop nodes.

### Note

If your Vertica cluster is configured to execute User Defined Extensions (UDxs) written in Java, it already has a correctly-configured JVM installed. See [Developing user-defined extensions \(UDxs\)](#) for more information.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the `JavaBinaryForUDx` configuration parameter to tell Vertica the location of the Java executable.

## Installing a Java runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6). Vertica supports runtimes from either Oracle or [OpenJDK](#). You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the [Java Standard Edition \(SE\) Download Page](#). You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

#### Note

Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

Setting the `JavaBinaryForUDx` configuration parameter

The `JavaBinaryForUDx` configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a [database superuser](#):

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See [ALTER DATABASE](#) for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the [CONFIGURATION\\_PARAMETERS](#) system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[RECORD 1]-----+-----
node_name | ALL
parameter_name | JavaBinaryForUDx
current_value | /usr/bin/java
default_value |
change_under_support_guidance | f
change_requires_restart | f
description | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

#### Note

Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

## Configuring Vertica for HCatalog

Before you can use the HCatalog Connector, you must add certain Hadoop and Hive libraries to your Vertica installation. You must also copy the Hadoop configuration files that specify various connection properties. Vertica uses the values in those configuration files to make its own connections to Hadoop.

You need only make these changes on one node in your cluster. After you do this you can install the HCatalog connector.

### Copy Hadoop libraries and configuration files

Vertica provides a tool, `hcatUtil`, to collect the required files from Hadoop. This tool copies selected libraries and XML configuration files from your Hadoop cluster to your Vertica cluster. This tool might also need access to additional libraries:

- If you plan to use Hive to query files that use Snappy compression, you need access to the Snappy native libraries, `libhadoop*.so` and `libsnapappy*.so`.
- If you plan to use Hive to query files that use LZO compression, you need access to the `hadoop-lzo-*.jar` and `libgplcompression.so*` libraries. In `core-site.xml` you must also edit the `io.compression.codecs` property to include `com.hadoop.compression.lzo.LzopCodec`.
- If you plan to use a JSON SerDe with a Hive table, you need access to its library. This is the same library that you used to configure Hive; for example:

```
hive> add jar /home/release/json-serde-1.3-jar-with-dependencies.jar;

hive> create external table nationjson (id int,name string,rank int,text string)
 ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
 LOCATION '/user/release/vt/nationjson';
```

- If you are using any other libraries that are not standard across all supported Hadoop versions, you need access to those libraries.

If any of these cases applies to you, do one of the following:

- Include the path(s) in the path you specify as the value of `--hcatLibPath`, or
- Copy the file(s) to a directory already on that path.

If Vertica is not co-located on a Hadoop node, you should do the following:

1. Copy `/opt/vertica/packages/hcat/tools/hcatUtil` to a Hadoop node and run it there, specifying a temporary output directory. Your Hadoop, HIVE, and HCatalog lib paths might be different. In newer versions of Hadoop the HCatalog directory is usually a subdirectory under the HIVE directory, and Cloudera creates a new directory for each revision of the configuration files. Use the values from your environment in the following command:

```
hcatUtil --copyJars
 --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
 --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
 --hcatLibPath="/tmp/hadoop-files"
```

If you are using Hive LLAP, specify the `hive2` directories.

2. Verify that all necessary files were copied:

```
hcatUtil --verifyJars --hcatLibPath=/tmp/hadoop-files
```

3. Copy that output directory (`/tmp/hadoop-files`, in this example) to `/opt/vertica/packages/hcat/lib` on the Vertica node you will connect to when installing the HCatalog connector. If you are updating a Vertica cluster to use a new Hadoop cluster (or a new version of Hadoop), first remove all JAR files in `/opt/vertica/packages/hcat/lib` except `vertica-hcatalogudl.jar`.
4. Verify that all necessary files were copied:

```
hcatUtil --verifyJars --hcatLibPath=/opt/vertica/packages/hcat
```

If Vertica is co-located on some or all Hadoop nodes, you can do this in one step on a shared node. Your Hadoop, HIVE, and HCatalog lib paths might be different; use the values from your environment in the following command:

```
hcatUtil --copyJars
 --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
 --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
 --hcatLibPath="/opt/vertica/packages/hcat/lib"
```

The `hcatUtil` script has the following arguments:

<code>-c, --copyJars</code>	Copy the required JAR files from <code>hadoopHiveHome</code> and configuration files from <code>hadoopHiveConfPath</code> .
<code>-v, --verifyJars</code>	Verify that the required files are present in <code>hcatLibPath</code> . Check the output of <code>hcatUtil</code> for error and warning messages.
<code>--hadoopHiveHome= "value1;value2;..."</code>	<p>Paths to the Hadoop, Hive, and HCatalog home directories. Separate directories by semicolons (;). Enclose paths in double quotes.</p> <p><b>Note</b> Always place <code>\$HADOOP_HOME</code> on the path before <code>\$HIVE_HOME</code>. In some Hadoop distributions, these two directories contain different versions of the same library.</p>
<code>--hadoopHiveConfPath= "value1;value2;..."</code>	<p>Paths of the following configuration files:</p> <ul style="list-style-type: none"> <li>• <code>hive-site.xml</code></li> <li>• <code>core-site.xml</code></li> <li>• <code>yarn-site.xml</code></li> <li>• <code>webhcat-site.xml</code> (optional with the default configuration; required if you use WebHCat instead of HiveServer2)</li> <li>• <code>hdfs-site.xml</code></li> </ul> <p>Separate directories by semicolons (;). Enclose paths in double quotes.</p> <p>In previous releases of Vertica this parameter was optional under some conditions. It is now required.</p>
<code>--hcatLibPath= "value"</code>	Output path for the libraries and configuration files. On a Vertica node, use <code>/opt/vertica/packages/hcat/lib</code> . If you have previously run <code>hcatUtil</code> with a different version of Hadoop, first remove the old JAR files from the output directory (all except <code>vertica-hcatalogudl.jar</code> ).

After you have copied the files and verified them, install the HCatalog connector.

Install the HCatalog Connector

On the same node where you copied the files from `hcatUtil`, install the HCatalog connector by running the `install.sql` script. This script resides in the `ddl/` folder under your HCatalog connector installation path. This script creates the library and `VHCatalogSource` and `VHCatalogParser`.

#### Note

The data that was copied using `hcatUtil` is now stored in the database. If you change any of those values in Hadoop, you need to rerun `hcatUtil` and `install.sql`. The following statement returns the names of the libraries and configuration files currently being used:

```
=> SELECT dependencies FROM user_libraries WHERE lib_name='VHCatalogLib';
```

Now you can create HCatalog schema parameters, which point to your existing Hadoop services, as described in [Defining a schema using the HCatalog Connector](#).

Upgrading to a new version of Vertica

After upgrading to a new version of Vertica, perform the following steps:

1. Uninstall the HCatalog Connector using the `uninstall.sql` script. This script resides in the `ddl/` folder under your HCatalog connector installation path.
2. Delete the contents of the `hcatLibPath` directory except for `vertica-hcatalogudl.jar`.
3. Rerun `hcatUtil`.
4. Reinstall the HCatalog Connector using the `install.sql` script.

For more information about upgrading Vertica, see [Upgrade Vertica](#).

Additional options for Hadoop columnar file formats

When reading Hadoop columnar file formats (ORC or Parquet), the HCatalog Connector attempts to use the built-in readers. When doing so, it uses WebHDFS by default. You can use the deprecated LibHDFS++ library by using the `hdfs` URI scheme and using [ALTER DATABASE](#) to set `HDFSUseWebHDFS` to 0. This setting applies to all HDFS access, not just the HCatalog Connector.

In either case, you must perform the configuration described in [Configuring HDFS access](#).

## Configuring security

You can use any of the security options described in [Accessing kerberized HDFS data](#) to access Hive data. This topic describes additional steps needed specifically for using the HCatalog Connector.

If you use Kerberos from Vertica, the HCatalog Connector can use an authorization service (Sentry or Ranger). If you use delegation tokens, you must manage authorization yourself.

### Kerberos

You can use Kerberos from Vertica as described in [Using Kerberos with Vertica](#).

How you configure the HCatalog Connector depends on how Hive manages authorization.

- If Hive uses Sentry to manage authorization, and if Sentry uses ACL synchronization, then the HCatalog Connector must access HDFS as the current user. Verify that the `EnableHCatImpersonation` configuration parameter is set to 1 (the default). ACL synchronization automatically provides authorized users with read access to the underlying HDFS files.
- If Hive uses Sentry without ACL synchronization, then the HCatalog Connector must access HDFS data as the Vertica principal. (The user still authenticates and accesses metadata normally.) Set the `EnableHCatImpersonation` configuration parameter to 0. The Vertica principal must have read access to the underlying HDFS files.
- If Hive uses Ranger to manage authorization, and the Vertica users have read access to the underlying HDFS files, then you can use user impersonation. Verify that the `EnableHCatImpersonation` configuration parameter is set to 1 (the default). You can, instead, disable user impersonation and give the Vertica principal read access to the HDFS files.
- If Hive uses either Sentry or Ranger, the HCatalog Connector must use `HiveServer2` (the default). WebHCat does not support authorization services.
- If Hive does not use an authorization service, or if you are connecting to Hive using WebHCat instead of `HiveServer2`, then the HCatalog Connector accesses Hive as the current user. Verify that `EnableHCatImpersonation` is set to 1. All users must have read access to the underlying HDFS files.

In addition, in your Hadoop configuration files (`core-site.xml` in most distributions), make sure that you enable all Hadoop components to impersonate the Vertica user. The easiest way to do so is to set the `proxyuser` property using wildcards for all users on all hosts and in all groups. Consult your Hadoop documentation for instructions. Make sure you set this property before running `hcatUtil` (see [Configuring Vertica for HCatalog](#)).

### Delegation tokens

You can use delegation tokens for a session as described in [Bring your own delegation token](#). When using the HCatalog Connector you specify two delegation tokens, one for the data and one for the metadata. The metadata token is tied to a Hive schema. See [HadoopImpersonationConfig format](#) for information about how to specify these two delegation tokens.

### Verifying security configuration

To verify that the HCatalog Connector can access Hive data, use the `HCATALOGCONNECTOR_CONFIG_CHECK` function.

For more information about testing your configuration, see [Verifying HDFS configuration](#).

## Defining a schema using the HCatalog Connector

After you set up the HCatalog Connector, you can use it to define a schema in your Vertica database to access the tables in a Hive database. You define the schema using the `CREATE HCATALOG SCHEMA` statement.

When creating the schema, you must supply the name of the schema to define in Vertica. Other parameters are optional. If you do not supply a value, Vertica uses default values. Vertica reads some default values from the HDFS configuration files; see [Configuration Parameters](#).

To create the schema, you must have read access to all Hive data. Verify that the user creating the schema has been granted access, either directly or through an authorization service such as Sentry or Ranger. The `dbadmin` user has no automatic special privileges.

After you create the schema, you can change many parameters using the `ALTER HCATALOG SCHEMA` statement.

After you define the schema, you can query the data in the Hive data warehouse in the same way you query a native Vertica table. The following example demonstrates creating an HCatalog schema and then querying several system tables to examine the contents of the new schema. See [Viewing Hive schema and table metadata](#) for more information about these tables.

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
 HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
 SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \x
Expanded display is on.
```

```
=> SELECT * FROM v_catalog.hcatalog_schemata;
-[RECORD 1]-----+-----
schema_id | 45035996273748224

hcatalog_user_name | admin
```

#### Configuration parameters

The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.

File	Properties
hive-site.xml	hive.server2.thrift.bind.host (used for HIVESERVER2_HOSTNAME)

	hive.server2.thrift.port
	hive.server2.transport.mode
	hive.server2.authentication
	hive.server2.authentication.kerberos.principal
	hive.server2.support.dynamic.service.discovery
	hive.zookeeper.quorum (used as HIVESERVER2_HOSTNAME if dynamic service discovery is enabled)
	hive.zookeeper.client.port
	hive.server2.zookeeper.namespace
	hive.metastore.uris (used for HOSTNAME and PORT)
ssl-client.xml	ssl.client.truststore.location
	ssl.client.truststore.password

### Using partitioned data

Hive supports partitioning data, as in the following example:

```
hive> create table users (name varchar(64), address string, city varchar(64))
partitioned by (state varchar(64)) stored as orc;
```

Vertica takes advantage of partitioning information for formats that provide it in metadata (ORC and Parquet). Queries can skip irrelevant partitions entirely (partition pruning), and Vertica does not need to materialize partition columns. For more about how to use partitions in Vertica, see [Partitioned data](#). For more information about how to create compatible partitions in Hive, see [Hive primer for Vertica integration](#).

By default Hive stores partition information under the path for the table definition, which might be local to Hive. However, a Hive user can choose to store partition information elsewhere, such as in a shared location like S3, as in the following example:

```
hive> alter table users add partition (state='MA')
location 's3a://DataLake/partitions/users/state=MA';
```

During query execution, therefore, Vertica must query Hive for the location of a table's partition information.

Because the additional Hive queries can be expensive, Vertica defaults to looking for partition information only in Hive's default location. If your Hive table specified a custom location, use the CUSTOM\_PARTITIONS parameter:

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcat' PORT=9083
HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin'
CUSTOM_PARTITIONS='yes';
```

Vertica can access partition locations in the S3 and S3a schemes, and does not support the S3n scheme.

The [HIVE\\_CUSTOM\\_PARTITIONS\\_ACCESSED](#) system table records all custom partition locations that have been used in queries.

### Using the HCatalog Connector with WebHCat

By default the HCatalog Connector uses HiveServer2 to access Hive data. If you are instead using WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0 before creating the schema as in the following example.

```
=> ALTER DATABASE DEFAULT SET PARAMETER HCatalogConnectorUseHiveServer2 = 0;
=> CREATE HCATALOG SCHEMA hcat WITH WEBSERVICE_HOSTNAME='webhcat.example.com';
```

If you have previously used WebHCat, you can switch to using HiveServer2 by setting the configuration parameter to 1 and using [ALTER HCATALOG SCHEMA](#) to set HIVESERVER2\_HOSTNAME. You do not need to remove the WebHCat values; the HCatalog Connector uses the value of HCatalogConnectorUseHiveServer2 to determine which parameters to use.

## Querying Hive tables using HCatalog Connector

Once you have defined the HCatalog schema, you can query data from the Hive database by using the schema name in your query.

```
=> SELECT * from hcat.messages limit 10;
messageid | userid | time | message
-----+-----+-----+-----
1 | nPfQ1ayhi | 2013-10-29 00:10:43 | hymenaeos cursus lorem Suspendis
2 | N7svORloZ | 2013-10-29 00:21:27 | Fusce ad sem vehicula morbi
3 | 4VvzN3d | 2013-10-29 00:32:11 | porta Vivamus condimentum
4 | heojkmTmc | 2013-10-29 00:42:55 | lectus quis imperdiet
5 | coROws3OF | 2013-10-29 00:53:39 | sit eleifend tempus a aliquam mauri
6 | oDRP1i | 2013-10-29 01:04:23 | risus facilisis sollicitudin sceler
7 | AU7a9Kp | 2013-10-29 01:15:07 | turpis vehicula tortor
8 | ZJWg185DkZ | 2013-10-29 01:25:51 | sapien adipiscing eget Aliquam tor
9 | E7ipAsYC3 | 2013-10-29 01:36:35 | varius Cum iaculis metus
10 | kStCv | 2013-10-29 01:47:19 | aliquam libero nascetur Cum mal
(10 rows)
```

Since the tables you access through the HCatalog Connector act like Vertica tables, you can perform operations that use both Hive data and native Vertica data, such as a join:

```
=> SELECT u.FirstName, u.LastName, d.time, d.Message from UserData u
-> JOIN hcat.messages d ON u.UserID = d.UserID LIMIT 10;
FirstName | LastName | time | Message
-----+-----+-----+-----
Whitney | Kerr | 2013-10-29 00:10:43 | hymenaeos cursus lorem Suspendis
Troy | Oneal | 2013-10-29 00:32:11 | porta Vivamus condimentum
Renee | Coleman | 2013-10-29 00:42:55 | lectus quis imperdiet
Fay | Moss | 2013-10-29 00:53:39 | sit eleifend tempus a aliquam mauri
Dominique | Cabrera | 2013-10-29 01:15:07 | turpis vehicula tortor
Mohammad | Eaton | 2013-10-29 00:21:27 | Fusce ad sem vehicula morbi
Cade | Barr | 2013-10-29 01:25:51 | sapien adipiscing eget Aliquam tor
Oprah | Mcmillan | 2013-10-29 01:36:35 | varius Cum iaculis metus
Astra | Sherman | 2013-10-29 01:58:03 | dignissim odio Pellentesque primis
Chelsea | Malone | 2013-10-29 02:08:47 | pede tempor dignissim Sed luctus
(10 rows)
```

## Viewing Hive schema and table metadata

When using Hive, you access metadata about schemas and tables by executing statements written in HiveQL (Hive's version of SQL) such as **SHOW TABLES**. When using the HCatalog Connector, you can get metadata about the tables in the Hive database through several Vertica system tables.

There are four system tables that contain metadata about the tables accessible through the HCatalog Connector:

- [HCATALOG\\_SCHEMATA](#) lists all of the schemas that have been defined using the HCatalog Connector.
- [HCATALOG\\_TABLE\\_LIST](#) contains an overview of all of the tables available from all schemas defined using the HCatalog Connector. This table only shows the tables that the user querying the table can access. The information in this table is retrieved using a single call to HiveServer2 for each schema defined using the HCatalog Connector, which means there is a little overhead when querying this table.
- [HCATALOG\\_TABLES](#) contains more in-depth information than HCATALOG\_TABLE\_LIST.
- [HCATALOG\\_COLUMNS](#) lists metadata about all of the columns in all of the tables available through the HCatalog Connector. As for HCATALOG\_TABLES, querying this table results in one call to HiveServer2 per table, and therefore can take a while to complete.

The following example demonstrates querying the system tables containing metadata for the tables available through the HCatalog Connector.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT * FROM HCATALOG_SCHEMATA;

### Synchronizing an HCatalog schema or table with a local schema or table

Querying data from an HCatalog schema can be slow due to Hive performance issues. This slow performance can be especially annoying when you want to examine the structure of the tables in the Hive database. Getting this information from Hive requires you to query the HCatalog schema's metadata using the HCatalog Connector.

To avoid this performance problem you can use the [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) function to create a snapshot of the HCatalog schema's metadata within a Vertica schema. You supply this function with the name of a pre-existing Vertica schema, typically the one created through CREATE HCATALOG SCHEMA, and a Hive schema available through the HCatalog Connector. You must have permission both in Vertica to write the data and in Hive and HDFS to read it.

#### Note

To synchronize a schema, you must have read permission for the underlying files in HDFS. If Hive uses Sentry to manage authorization, then you can use ACL synchronization to manage HDFS access. Otherwise, the user of this function must have read access in HDFS.

The function creates a set of external tables within the Vertica schema that you can then use to examine the structure of the tables in the Hive database. Because the metadata in the Vertica schema is local, query planning is much faster. You can also use standard Vertica statements and system-table queries to examine the structure of Hive tables in the HCatalog schema.

#### Caution

The SYNC\_WITH\_HCATALOG\_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

When SYNC\_WITH\_HCATALOG\_SCHEMA creates tables in Vertica, it matches Hive's STRING and BINARY types to Vertica's VARCHAR(65000) and VARBINARY(65000) types. You might want to change these lengths, using [ALTER TABLE SET DATA TYPE](#), in two cases:

- If the value in Hive is larger than 65000 bytes, increase the size and use LONG VARCHAR or LONG VARBINARY to avoid data truncation. If a Hive string uses multi-byte encodings, you must increase the size in Vertica to avoid data truncation. This step is needed because Hive counts string length in characters while Vertica counts it in bytes.
- If the value in Hive is much smaller than 65000 bytes, reduce the size to conserve memory in Vertica.

The Vertica schema is just a snapshot of the HCatalog schema's metadata. Vertica does not synchronize later changes to the HCatalog schema with the local schema after you call SYNC\_WITH\_HCATALOG\_SCHEMA. You can call the function again to re-synchronize the local schema to the HCatalog schema. If you altered column data types, you will need to repeat those changes because the function creates new external tables.

By default, SYNC\_WITH\_HCATALOG\_SCHEMA does not drop tables that appear in the local schema that do not appear in the HCatalog schema. Thus, after the function call the local schema does not reflect tables that have been dropped in the Hive database since the previous call. You can change this behavior by supplying the optional third Boolean argument that tells the function to drop any table in the local schema that does not correspond to a table in the HCatalog schema.

Instead of synchronizing the entire schema, you can synchronize individual tables by using [SYNC\\_WITH\\_HCATALOG\\_SCHEMA\\_TABLE](#). If the table already exists in Vertica the function overwrites it. If the table is not found in the HCatalog schema, this function returns an error. In all other respects this function behaves in the same way as SYNC\_WITH\_HCATALOG\_SCHEMA.

If you change the settings of any HCatalog Connector configuration parameters ( [Hadoop parameters](#) ), you must call this function again.

#### Examples

The following example demonstrates calling SYNC\_WITH\_HCATALOG\_SCHEMA to synchronize the HCatalog schema in Vertica with the metadata in Hive. Because it synchronizes the HCatalog schema directly, instead of synchronizing another schema with the HCatalog schema, both arguments are the same.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
 HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema

Schema hcat synchronized with hcat
tables in hcat = 56
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)

=> -- Use vsq!s \d command to describe a table in the synced schema

=> \d hcat.messages
List of Fields by Tables
 Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
 hcat | messages | id | int | 8 | | f | f |
 hcat | messages | userid | varchar(65000) | 65000 | | f | f |
 hcat | messages | "time" | varchar(65000) | 65000 | | f | f |
 hcat | messages | message | varchar(65000) | 65000 | | f | f |
(4 rows)
```

This example shows synchronizing with a schema created using CREATE HCATALOG SCHEMA. Synchronizing with a schema created using CREATE SCHEMA is also supported.

You can query tables in the local schema that you synchronized with an HCatalog schema. However, querying tables in a synchronized schema isn't much faster than directly querying the HCatalog schema, because SYNC\_WITH\_HCATALOG\_SCHEMA only duplicates the HCatalog schema's metadata. The data in the table is still retrieved using the HCatalog Connector.

#### Data type conversions from Hive to Vertica

The data types recognized by Hive differ from the data types recognized by Vertica. The following table lists how the HCatalog Connector converts Hive data types into data types compatible with Vertica.

Hive Data Type	Vertica Data Type
TINYINT (1-byte)	TINYINT (8-bytes)
SMALLINT (2-bytes)	SMALLINT (8-bytes)
INT (4-bytes)	INT (8-bytes)

BIGINT (8-bytes)	BIGINT (8-bytes)
BOOLEAN	BOOLEAN
FLOAT (4-bytes)	FLOAT (8-bytes)
DECIMAL (precision, scale)	DECIMAL (precision, scale)
DOUBLE (8-bytes)	DOUBLE PRECISION (8-bytes)
CHAR (length in characters)	CHAR (length in bytes)
VARCHAR (length in characters)	VARCHAR (length in bytes), if length <= 65000 LONG VARCHAR (length in bytes), if length > 65000
STRING (2 GB max)	VARCHAR (65000)
BINARY (2 GB max)	VARBINARY (65000)
DATE	DATE
TIMESTAMP	TIMESTAMP
LIST/ARRAY	VARCHAR (65000) containing a JSON-format representation of the list.
MAP	VARCHAR (65000) containing a JSON-format representation of the map.
STRUCT	VARCHAR (65000) containing a JSON-format representation of the struct.

#### Data-width handling differences between Hive and Vertica

The HCatalog Connector relies on Hive SerDe classes to extract data from files on HDFS. Therefore, the data read from these files are subject to Hive's data width restrictions. For example, suppose the SerDe parses a value for an INT column into a value that is greater than  $2^{32} - 1$  (the maximum value for a 32-bit integer). In this case, the value is rejected even if it would fit into a Vertica's 64-bit INTEGER column because it cannot fit into Hive's 32-bit INT.

Hive measures CHAR and VARCHAR length in characters and Vertica measures them in bytes. Therefore, if multi-byte encodings are being used (like Unicode), text might be truncated in Vertica.

Once the value has been parsed and converted to a Vertica data type, it is treated as native data. This treatment can result in some confusion when comparing the results of an identical query run in Hive and in Vertica. For example, if your query adds two INT values that result in a value that is larger than  $2^{32} - 1$ , the value overflows its 32-bit INT data type, causing Hive to return an error. When running the same query with the same data in Vertica using the HCatalog Connector, the value will probably still fit within Vertica's 64-bit int value. Thus the addition is successful and returns a value.

#### Using nonstandard SerDes

Hive stores its data in unstructured flat files located in the Hadoop Distributed File System (HDFS). When you execute a Hive query, it uses a set of serializer and deserializer (SerDe) classes to extract data from these flat files and organize it into a relational database table. For Hive to be able to extract data from a file, it must have a SerDe that can parse the data the file contains. When you create a table in Hive, you can select the SerDe to be used for the table's data.

Hive has a set of standard SerDes that handle data in several formats such as delimited data and data extracted using regular expressions. You can also use third-party or custom-defined SerDes that allow Hive to process data stored in other file formats. For example, some commonly-used third-party SerDes handle data stored in JSON format.

The HCatalog Connector directly fetches file segments from HDFS and uses Hive's SerDes classes to extract data from them. The Connector includes all Hive's standard SerDes classes, so it can process data stored in any file that Hive natively supports. If you want to query data from a Hive table that uses a custom SerDe, you must first install the SerDe classes on the Vertica cluster.

#### Determining which SerDe you need

If you have access to the Hive command line, you can determine which SerDe a table uses by using Hive's SHOW CREATE TABLE statement. This statement shows the HiveQL statement needed to recreate the table. For example:

```
hive> SHOW CREATE TABLE msgjson;
OK
CREATE EXTERNAL TABLE msgjson(
messageid int COMMENT 'from deserializer',
userid string COMMENT 'from deserializer',
time string COMMENT 'from deserializer',
message string COMMENT 'from deserializer')
ROW FORMAT SERDE
'org.apache.hadoop.hive.contrib.serde2.JsonSerde'
STORED AS INPUTFORMAT
'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
'hdfs://hivehost.example.com:8020/user/exampleuser/msgjson'
TBLPROPERTIES (
'transient_lastDdlTime'='1384194521')
Time taken: 0.167 seconds
```

In the example, **ROW FORMAT SERDE** indicates that a special SerDe is used to parse the data files. The next row shows that the class for the SerDe is named `org.apache.hadoop.hive.contrib.serde2.JsonSerde`. You must provide the HCatalog Connector with a copy of this SerDe class so that it can read the data from this table.

You can also find out which SerDe class you need by querying the table that uses the custom SerDe. The query will fail with an error message that contains the class name of the SerDe needed to parse the data in the table. In the following example, the portion of the error message that names the missing SerDe class is in bold.

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [

. . .
```

### Installing the SerDe on the Vertica cluster

You usually have two options to getting the SerDe class file the HCatalog Connector needs:

- Find the installation files for the SerDe, then copy those over to your Vertica cluster. For example, there are several third-party JSON SerDes available from sites like Google Code and GitHub. You may find the one that matches the file installed on your Hive cluster. If so, then download the package and copy it to your Vertica cluster.
- Directly copy the JAR files from a Hive server onto your Vertica cluster. The location for the SerDe JAR files depends on your Hive installation. On some systems, they may be located in `/usr/lib/hive/lib`.

Wherever you get the files, copy them into the `/opt/vertica/packages/hcat/lib` directory on every node in your Vertica cluster.

### Important

If you add a new host to your Vertica cluster, remember to copy every custom SerDer JAR file to it.

### Troubleshooting HCatalog Connector problems

You may encounter the following issues when using the HCatalog Connector.

## Connection errors

The HCatalog Connector can encounter errors both when you define a schema and when you query it. The types of errors you get depend on which CREATE HCATALOG SCHEMA parameters are incorrect. Suppose you have incorrect parameters for the metastore database, but correct parameters for HiveServer2. In this case, HCatalog-related system table queries succeed, while queries on the HCatalog schema fail. The following example demonstrates creating an HCatalog schema with the correct default HiveServer2 information. However, the port number for the metastore database is incorrect.

```
=> CREATE HCATALOG SCHEMA hcat2 WITH hostname='hcahost'
-> HCATALOG_SCHEMA='default' HCATALOG_USER='hive' PORT=1234;
CREATE SCHEMA
=> SELECT * FROM HCATALOG_TABLE_LIST;
-[RECORD 1]-----+-----
table_schema_id | 45035996273864536
table_schema | hcat2
hcatalog_schema | default
table_name | test
hcatalog_user_name | hive

=> SELECT * FROM hcat2.test;
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not
initialized, setOutput has to be called. Cause : java.io.IOException:
MetaException(message:Could not connect to meta store using any of the URIs
provided. Most recent failure: org.apache.thrift.transport.TTTransportException:
java.net.ConnectException:
Connection refused
at org.apache.thrift.transport.TSocket.open(TSocket.java:185)
at org.apache.hadoop.hive.metastore.HiveMetaStoreClient.open(
HiveMetaStoreClient.java:277)
. . .
```

To resolve these issues, you must drop and recreate the schema or alter the schema to correct the parameters. If you still have issues, determine whether there are connectivity issues between your Vertica cluster and your Hadoop cluster. Such issues can include a firewall that prevents one or more Vertica hosts from contacting the HiveServer2, metastore, or HDFS hosts.

### UDx failure when querying data: error 3399

You might see an error message when querying data (as opposed to metadata like schema information). This might be accompanied by a `ClassNotFoundException` in the log. This can happen for the following reasons:

- You are not using the same version of Java on your Hadoop and Vertica nodes. In this case you need to change one of them to match the other.
- You have not used `hcatUtil` to copy all Hadoop and Hive libraries and configuration files to Vertica, or you ran `hcatutil` and then changed your version of Hadoop or Hive.
- You upgraded Vertica to a new version and did not rerun `hcatutil` and reinstall the HCatalog Connector.
- The version of Hadoop you are using relies on a third-party library that you must copy manually.
- You are reading files with LZO compression and have not copied the libraries or set the `io.compression.codecs` property in `core-site.xml`.
- You are reading Parquet data from Hive, and columns were added to the table after some data was already present in the table. Adding columns does not update existing data, and the `ParquetSerDe` provided by Hive and used by the HCatalog Connector does not handle this case. This error is due to a limitation in Hive and there is no workaround.
- The query is taking too long and is timing out. If this is a frequent problem, you can increase the value of the `UDxFencedBlockTimeout` configuration parameter. See [General parameters](#).

If you did not copy the libraries or configure LZO compression, follow the instructions in [Configuring Vertica for HCatalog](#).

If the Hive jars that you copied from Hadoop are out of date, you might see an error message like the following:

```
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [Found interface org.apache.hadoop.mapreduce.JobContext, but
class was expected]
HINT hive metastore service is thrift://localhost:13433 (check UDXLogs/UDxFencedProcessesJava.log
in the catalog directory for more information)
```

This error usually signals a problem with [hive-hcatalog-core jar](#) . Make sure you have an up-to-date copy of this file. Remember that if you rerun hcatUtil you also need to re-create the HCatalog schema.

You might also see a different form of this error:

```
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [javax/servlet/Filter]
```

This error can be reported even if hcatUtil reports that your libraries are up to date. The [javax.servlet.Filter](#) class is in a library that some versions of Hadoop use but that is not usually part of the Hadoop installation directly. If you see an error mentioning this class, locate [servlet-api-\\*.jar](#) on a Hadoop node and copy it to the [hcat/lib](#) directory on all database nodes. If you cannot locate it on a Hadoop node, locate and download it from the Internet. (This case is rare.) The library version must be 2.3 or higher.

After you have copied the jar to the [hcat/lib](#) directory, reinstall the HCatalog connector as explained in [Configuring Vertica for HCatalog](#) .

Authentication error when querying data

You might have successfully created a schema using CREATE HCATALOG SCHEMA but get errors at query time such as the following:

```
=> SELECT * FROM hcat.clickdata;
ERROR 6776: Failed to glob [hdfs:///user/hive/warehouse/click-*.parquet]
because of error: hdfs:///user/hive/warehouse/click-12214.parquet: statAll failed;
error: AuthenticationFailed
```

You might see this error if Hive uses an authorization service. If the permissions on the underlying files in HDFS match those in the authorization service, then Vertica must use user impersonation when accessing that data. To enable user impersonation, set the EnableHCatImpersonation configuration parameter to 1.

Vertica uses the database principal to access HDFS. Therefore, if EnableHCatImpersonation is 0, the Vertica database principal must have access to the data inside the hive warehouse on HDFS. If it does not, you might see the following error:

```
=> SELECT * FROM hcat.salesdata;
ERROR 6776: Failed to glob [vertica-hdfs:///hive/warehouse/sales/*/*]
because of error: vertica-hdfs:///hive/warehouse/sales/: listStat failed;
error: Permission denied: user=vertica, access=EXECUTE, inode="/hive/warehouse/sales":hdfs:hdfs:d-----
```

The URL scheme in this error message has been changed from [hdfs](#) to [vertica-hdfs](#) . This is an internal scheme and is not valid in URLs outside of Vertica. You cannot use this scheme when specifying paths in HDFS.

Differing results between Hive and Vertica queries

Sometimes, running the same query on Hive and on Vertica through the HCatalog Connector can return different results. There are a few common causes of this problem.

This discrepancy is often caused by the differences between the data types supported by Hive and Vertica. See [Data type conversions from Hive to Vertica](#) for more information about supported data types.

If Hive string values are being truncated in Vertica, this might be caused by multi-byte character encodings in Hive. Hive reports string length in characters, while Vertica records it in bytes. For a two-byte encoding such as Unicode, you need to double the column size in Vertica to avoid truncation.

Discrepancies can also occur if the Hive table uses partition columns of types other than string.

If the Hive table stores partition data in custom locations instead of the default, you will see different query results if you do not specify the CUSTOM\_PARTITIONS parameter when creating the Vertica schema. See [Using Partitioned Data](#) . Further, even when using custom partitions, there are differences between Vertica and Hive:

- If a custom partition is unavailable at query time, Hive ignores it and returns the rest of the results. Vertica reports an error.
- If a partition is altered in Hive to use a custom location after table creation, Hive reads data from only the new location while Vertica reads data from both the default and the new locations.
- If a partition value and its corresponding directory name disagree, Hive uses the value in its metadata while Vertica uses the value in the directory name.

The following example illustrates these differences. A table in Hive, partitioned on the state column, starts with the following data:

```
hive> select * from inventory;
+-----+-----+-----+
| inventory.ID | inventory.quant | inventory.state |
+-----+-----+-----+
| 2 | 300 | CA |
| 4 | 400 | CA |
| 5 | 500 | DC |
| 1 | 100 | PA |
| 2 | 200 | PA |
+-----+-----+-----+
```

The partition for one state, CA, is then moved. This directory contains some data already. Note that the query now returns different results for the CA partitions.

```
hive> ALTER TABLE inventory PARTITION (state='CA') SET LOCATION 'hdfs:///partitions/inventory/state=MD';
hive> select * from inventory;
+-----+-----+-----+
| inventory.ID | inventory.quant | inventory.state |
+-----+-----+-----+
| 20 | 30000 | CA |
| 40 | 40000 | CA |
| 5 | 500 | DC |
| 1 | 100 | PA |
| 2 | 200 | PA |
+-----+-----+-----+
5 rows selected (0.399 seconds)
```

The CA partitions were moved to a directory named state=MD. Vertica reports the state for the first two rows, the ones in the new partition location, as MD because of the directory name. It also reports the CA values from the original location in addition to the new one:

```
=> SELECT * FROM hcat.inventory;
ID | quant | state
-----+-----+-----
20 | 30000 | MD
40 | 40000 | MD
2 | 300 | CA
4 | 400 | CA
1 | 100 | PA
2 | 200 | PA
5 | 500 | DC
(7 rows)
```

### HCatalog Connector installation fails on MapR

If you mount a MapR file system as an NFS mount point and then install the HCatalog Connector, it could fail with a message like the following:

```
ROLLBACK 2929: Couldn't create new UDX side process,
failed to get UDX side process info from zygoter: Broken pipe
```

This might be accompanied by an error like the following in [dbLog](#) :

```
java.io.IOException: Couldn't get lock for /home/dbadmin/node02_catalog/UDxLogs/UDxFencedProcessesJava.log
 at java.util.logging.FileHandler.openFiles(FileHandler.java:389)
 at java.util.logging.FileHandler.<init>(FileHandler.java:287)
 at com.vertica.udxfence.UDxLogger.setup(UDxLogger.java:78)
 at com.vertica.udxfence.UDxSideProcess.go(UDxSideProcess.java:75)
 ...
```

This error occurs if you locked your NFS mount point when creating it. Locking is the default. If you use the HCatalog Connector with MapR mounted as an NFS mount point, you must create the mount point with the `-o nolock` option. For example:

```
sudo mount -o nolock -t nfs MaprCLDBserviceHostname:/mapr/ClusterName/vertica/${hostname -f}/ vertica
```

You can use the HCatalog Connector with MapR without mounting the MapR file system. If you mount the MapR file system, you must do so without a lock.

## Excessive query delays

Network issues or high system loads on the HiveServer2 server can cause long delays while querying a Hive database using the HCatalog Connector. While Vertica cannot resolve these issues, you can set parameters that limit how long Vertica waits before canceling a query on an HCatalog schema. You can set these parameters globally using Vertica configuration parameters. You can also set them for specific HCatalog schemas in the [CREATE HCATALOG SCHEMA](#) statement. These specific settings override the settings in the configuration parameters.

The HCatConnectionTimeout configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG\_CONNECTION\_TIMEOUT parameter control how many seconds the HCatalog Connector waits for a connection to the HiveServer2 server. A value of 0 (the default setting for the configuration parameter) means to wait indefinitely. If the server does not respond by the time this timeout elapses, the HCatalog Connector breaks the connection and cancels the query. If you find that some queries on an HCatalog schema pause excessively, try setting this parameter to a timeout value, so the query does not hang indefinitely.

The HCatSlowTransferTime configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG\_SLOW\_TRANSFER\_TIME parameter specify how long the HCatalog Connector waits for data after making a successful connection to the server. After the specified time has elapsed, the HCatalog Connector determines whether the data transfer rate from the server is at least the value set in the HCatSlowTransferLimit configuration parameter (or by the CREATE HCATALOG SCHEMA statement's HCATALOG\_SLOW\_TRANSFER\_LIMIT parameter). If it is not, then the HCatalog Connector terminates the connection and cancels the query.

You can set these parameters to cancel queries that run very slowly but do eventually complete. However, query delays are usually caused by a slow connection rather than a problem establishing the connection. Therefore, try adjusting the slow transfer rate settings first. If you find the cause of the issue is connections that never complete, you can alternately adjust the Linux TCP socket timeouts to a suitable value instead of relying solely on the HCatConnectionTimeout parameter.

## Serde errors

Errors can occur if you attempt to query a Hive table that uses a nonstandard SerDe. If you have not installed the SerDe JAR files on your Vertica cluster, you receive an error similar to the one in the following example:

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not
initialized, setOutput has to be called. Cause : java.io.IOException:
java.lang.RuntimeException:
MetaException(message:org.apache.hadoop.hive.serde2.SerdeException
Serde com.cloudera.hive.serde.JSONSerDe does not exist)] HINT If error
message is not descriptive or local, may be we cannot read metadata from hive
metastore service thrift://hcathost:9083 or HDFS namenode (check
UDXLogs/UDXFencedProcessesJava.log in the catalog directory for more information)
at com.vertica.hcatalogudl.HCatalogSplitsNoOpSourceFactory
.plan(HCatalogSplitsNoOpSourceFactory.java:98)
at com.vertica.udxfence.UDXExecContext.planUDSource(UDXExecContext.java:898)
. . .
```

In the error message, you can see that the root cause is a missing SerDe class (shown in bold). To resolve this issue, install the SerDe class on your Vertica cluster. See [Using nonstandard SerDes](#) for more information.

This error may occur intermittently if just one or a few hosts in your cluster do not have the SerDe class.

## Integrating with Cloudera Manager

The Cloudera distribution of Hadoop includes Cloudera Manager, a web-based tool for managing a Hadoop cluster. Cloudera Manager can manage any service for which a service description is available, including Vertica.

You can use Cloudera Manager to start, stop, and monitor individual database nodes or the entire database. You can manage both co-located and separate Vertica clusters—Cloudera can manage services on nodes that are not part of the Hadoop cluster.

You must install and configure your Vertica database before proceeding; you cannot use Cloudera Manager to create the database.

### Installing the service

#### Note

Because the service has to send the database password over the network, you should enable encryption on your Hadoop cluster before

A Cloudera Service Description (CSD) file describes a service that Cloudera can manage. The Vertica CSD is in `/opt/vertica/share/CSD` on a database node.

To install the Vertica CSD, follow these steps:

1. On a Vertica node, follow the instructions in [VerticaAPIKey](#) to generate an API key. You need this key to finish the installation of the CSD.
2. On the Hadoop node that hosts Cloudera Manager, copy the CSD file into `/opt/cloudera/csd`.
3. Restart Cloudera Manager:

```
$ service cloudera-scm-server restart
```

4. In a web browser, go to Cloudera Manager and restart the Cloudera Management Service.
5. If your Vertica cluster is separate from your Hadoop cluster (not co-located on it): Use Cloudera Manager to add the hosts for your database nodes. If your cluster is co-located, skip this step.
6. Use Cloudera Manager to add the Vertica service.
7. On the "Role Assignment" page, select the hosts that are database nodes.
8. On the "Configuration" page, specify values for the following fields:
  - database name
  - agent port (accept the default if you're not sure)
  - API key
  - database user to run as (usually dbadmin) and password

### About the agent

When you manage Vertica through Cloudera Manager, you are actually interacting with the Vertica Agent, not the database directly. The [Agent](#) runs on all database nodes and interacts with the database on your behalf. Management Console uses the same agent. Most of the time this extra indirection is transparent to you.

A Cloudera-managed service contains one or more roles. In this case the service is "Vertica" and the single role is "Vertica Node".

### Available operations

Cloudera Manager shows two groups of operations. Service-level operations apply to the service on all nodes, while role-level operations apply only to a single node.

You can perform the following service-level operations on all nodes:

- Start: Starts the agent and, if it is not already running, the database.
- Stop: Stops the database and agent.
- Restart: Calls Stop and then Start.
- Add Role Instances: Adds new database nodes to Cloudera Manager. The nodes must already be part of the Vertica cluster, and the hosts must already be known to Cloudera Manager.
- Enter Maintenance Mode: Suppresses health alerts generated by Cloudera Manager.
- Exit Maintenance Mode: Resumes normal reporting.
- Update Memory Pool Size: Applies memory-pool settings from the Static Service Pools configuration page.

You can perform all of these operations except Add Role Instances on individual nodes as role-level operations.

### Managing memory pools

Cloudera Manager allows you to change resource allocations, such as memory and CPU, for the nodes it manages. If you are using co-located clusters, centrally managing resources can simplify your cluster management. If you are using separate Hadoop and Vertica clusters, you might prefer to manage Vertica separately as described in [Managing the database](#).

Use the Cloudera Manager "Static Service Pools" configuration page to configure resource allocations. The "Vertica Memory Pool" value, specified in GB, is the maximum amount of memory to allocate to the database on each node. If the configuration page includes "Cgroup Memory Hard Limit", set it to the same value as "Vertica Memory Pool".

After you have set these values, you can use the "Update Memory Pool Size" operation to apply the value to the managed nodes. This operation is equivalent to `ALTER RESOURCE POOL GENERAL MAXMEMORYSIZE`. Configuration changes in "Static Service Pools" do not take effect in Vertica until you perform this operation.

### Uninstalling the service

To uninstall the Vertica CSD, follow these steps:

1. Stop the Vertica service and then remove it from Cloudera Manager.
2. Remove the CSD file from `/opt/cloudera/csd`.
3. From the command line, restart the Cloudera Manager server.
4. In Cloudera Manager, restart the Cloudera Management Service.

## Integrating Vertica with the MapR distribution of Hadoop

MapR is a distribution of Apache Hadoop produced by MapR Technologies that extends the standard Hadoop components with its own features. Vertica can integrate with MapR in the following ways:

- You can read data from MapR through an NFS mount point. After you mount the MapR file system as an NFS mount point, you can use [CREATE EXTERNAL TABLE AS COPY](#) or [COPY](#) to access the data as if it were on the local file system. This option provides the best performance for reading data.
- You can use the HCatalog Connector to read Hive data. Do not use the HCatalog Connector with ORC or Parquet data in MapR for performance reasons. Instead, mount the MapR file system as an NFS mount point and create external tables without using the Hive schema. For more about reading Hive data, see [Using the HCatalog Connector](#).
- You can create a storage location to store data in MapR using the native Vertica format (ROS). Mount the MapR file system as an NFS mount point and then use [CREATE LOCATION](#)...ALL NODES SHARED to create a storage location. (CREATE LOCATION does not support NFS mount points in general, but does support them for MapR.)

### Note

If you create a Vertica database and place its initial storage location on MapR, Vertica designates the storage location for both DATA and TEMP usage. Vertica does not support TEMP storage locations on MapR, so after you create the location, you must alter it to store only DATA files. See [Altering location use](#). Ensure that you have a TEMP location on the Linux file system.

Other Vertica integrations for Hadoop are not available for MapR.

For information on mounting the MapR file system as an NFS mount point, see [Accessing Data with NFS](#) and [Configuring Vertica Analytics Platform with MapR](#) on the MapR website. In particular, you must configure MapR to add Vertica as a MapR service.

### Examples

In the following examples, the MapR file system has been mounted as `/mapr`.

The following statement creates an external table from ORC data:

```
=> CREATE EXTERNAL TABLE t (a1 INT, a2 VARCHAR(20))
AS COPY FROM '/mapr/data/file.orc' ORC;
```

The following statement creates an external table from Parquet data and takes advantage of partition pruning (see [Partitioned data](#)):

```
=> CREATE EXTERNAL TABLE t2 (id int, name varchar(50), created date, region varchar(50))
AS COPY FROM '/mapr/*/*/*' PARTITION COLUMNS created, region PARQUET();
```

The following statement loads ORC data from MapR into Vertica:

```
=> COPY t FROM '/mapr/data/*.orc' ON ANY NODE ORC;
```

The following statements create a storage location to hold ROS data in the MapR file system:

```
=> CREATE LOCATION '/mapr/my.cluster.com/data' SHARED USAGE 'DATA' LABEL 'maprfs';

=> SELECT ALTER_LOCATION_USE('/mapr/my.cluster.com/data', '', 'DATA');
```

## Hive primer for Vertica integration

You can use Hive to export data for use by Vertica. Decisions you make when doing the Hive export affect performance in Vertica.

### Tuning ORC stripes and Parquet rowgroups

Vertica can read ORC and Parquet files generated by any Hive version. However, newer Hive versions store more metadata in these files. This metadata is used by both Hive and Vertica to prune values and to read only the required data. Use the latest Hive version to store data in these formats. ORC and Parquet are fully forward- and backward-compatible. To get the best performance, use Hive 0.14 or later.

The ORC format splits a table into groups of rows called stripes and stores column-level metadata in each stripe. The Parquet format splits a table into groups of rows called rowgroups and stores column-level metadata in each rowgroup. Each stripe/rowgroup's metadata is used during predicate evaluation to determine whether the values from this stripe need to be read. Large stripes usually yield better performance, so set the stripe size to at least 256M.

Hive writes ORC stripes and Parquet rowgroups to HDFS, which stores data in HDFS blocks distributed among multiple physical data nodes. Accessing an HDFS block requires opening a separate connection to the corresponding data node. It is advantageous to ensure that an ORC stripe or Parquet rowgroup does not span more than one HDFS block. To do so, set the HDFS block size to be larger than the stripe/rowgroup size. Setting HDFS block size to 512M is usually sufficient.

Hive provides three compression options: None, Snappy, and Zlib. Use Snappy or Zlib compression to reduce storage and I/O consumption. Usually, Snappy is less CPU-intensive but can yield lower compression ratios compared to Zlib.

Storing data in sorted order can improve data access and predicate evaluation performance. Sort table columns based on the likelihood of their occurrence in query predicates; columns that most frequently occur in comparison or range predicates should be sorted first.

Partitioning tables is a very useful technique for data organization. Similarly to sorting tables by columns, partitioning can improve data access and predicate evaluation performance. Vertica supports Hive-style partitions and partition pruning.

The following Hive statement creates an ORC table with stripe size 256M and Zlib compression:

```
hive> CREATE TABLE customer_visits (
 customer_id bigint,
 visit_num int,
 page_view_dt date)
 STORED AS ORC tblproperties("orc.compress"="ZLIB",
 "orc.stripe.size"="268435456");
```

The following statement creates a Parquet table with stripe size 256M and Zlib compression:

```
hive> CREATE TABLE customer_visits (
 customer_id bigint,
 visit_num int,
 page_view_dt date)
 STORED AS PARQUET tblproperties("parquet.compression"="ZLIB",
 "parquet.stripe.size"="268435456");
```

### Creating sorted files in Hive

Unlike Vertica, Hive does not store table columns in separate files and does not create multiple projections per table with different sort orders. For efficient data access and predicate pushdown, sort Hive table columns based on the likelihood of their occurrence in query predicates. Columns that most frequently occur in comparison or range predicates should be sorted first.

Data can be inserted into Hive tables in a sorted order by using the ORDER BY or SORT BY keywords. For example, to insert data into the ORC table "customer\_visit" from another table "visits" with the same columns, use these keywords with the INSERT INTO command:

```
hive> INSERT INTO TABLE customer_visits
 SELECT * from visits
 ORDER BY page_view_dt;
```

```
hive> INSERT INTO TABLE customer_visits
 SELECT * from visits
 SORT BY page_view_dt;
```

The difference between the two keywords is that ORDER BY guarantees global ordering on the entire table by using a single MapReduce reducer to populate the table. SORT BY uses multiple reducers, which can cause ORC or Parquet files to be sorted by the specified column(s) but not be globally sorted. Using the latter keyword can increase the time taken to load the file.

You can combine clustering and sorting to sort a table globally. The following table definition adds a hint that data is inserted into this table bucketed by customer\_id and sorted by page\_view\_dt:

```
hive> CREATE TABLE customer_visits_bucketed (
 customer_id bigint,
 visit_num int,
 page_view_dt date)
CLUSTERED BY (page_view_dt)
SORTED BY (page_view_dt) INTO 10 BUCKETS
STORED AS ORC;
```

When inserting data into the table, you must explicitly specify the clustering and sort columns, as in the following example:

```
hive> INSERT INTO TABLE customer_visits_bucketed
SELECT * from visits
DISTRIBUTE BY page_view_dt
SORT BY page_view_dt;
```

The following statement is equivalent:

```
hive> INSERT INTO TABLE customer_visits_bucketed
SELECT * from visits
CLUSTER BY page_view_dt;
```

Both of the above commands insert data into the customer\_visits\_bucketed table, globally sorted on the page\_view\_dt column.

### Partitioning Hive tables

Table partitioning in Hive is an effective technique for data separation and organization, as well as for reducing storage requirements. To partition a table in Hive, include it in the PARTITIONED BY clause:

```
hive> CREATE TABLE customer_visits (
 customer_id bigint,
 visit_num int)
PARTITIONED BY (page_view_dt date)
STORED AS ORC;
```

Hive does not materialize partition column(s). Instead, it creates subdirectories of the following form:

```
path_to_table/partition_column_name=value/
```

When the table is queried, Hive parses the subdirectories' names to materialize the values in the partition columns. The value materialization in Hive is a plain conversion from a string to the appropriate data type.

Inserting data into a partitioned table requires specifying the value(s) of the partition column(s). The following example creates two partition subdirectories, "customer\_visits/page\_view\_dt=2016-02-01" and "customer\_visits/page\_view\_dt=2016-02-02":

```
hive> INSERT INTO TABLE customer_visits
PARTITION (page_view_dt='2016-02-01')
SELECT customer_id, visit_num from visits
WHERE page_view_dt='2016-02-01'
ORDER BY page_view_dt;

hive> INSERT INTO TABLE customer_visits
PARTITION (page_view_dt='2016-02-02')
SELECT customer_id, visit_num from visits
WHERE page_view_dt='2016-02-02'
ORDER BY page_view_dt;
```

Each directory contains ORC files with two columns, customer\_id and visit\_num.

Example: a partitioned, sorted ORC table

Suppose you have data stored in CSV files containing three columns: customer\_id, visit\_num, page\_view\_dtm:

```
1,123,2016-01-01
33,1,2016-02-01
2,57,2016-01-03
...
```

The goal is to create the following Hive table:

```
hive> CREATE TABLE customer_visits (
 customer_id bigint,
 visit_num int)
PARTITIONED BY (page_view_dt date)
STORED AS ORC;
```

To achieve this, perform the following steps:

1. Copy or move the CSV files to HDFS.
2. Define a textfile Hive table and copy the CSV files into it:

```
hive> CREATE TABLE visits (
 customer_id bigint,
 visit_num int,
 page_view_dt date)
ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
STORED AS TEXTFILE;

hive> LOAD DATA INPATH path_to_csv_files INTO TABLE visits;
```

3. For each unique value in `page_view_dt`, insert the data into the target table while materializing `page_view_dt` as `page_view_dtm`:

```
hive> INSERT INTO TABLE customer_visits
PARTITION (page_view_dt='2016-01-01')
SELECT customer_id, visit_num FROM visits
WHERE page_view_dt='2016-01-01'
ORDER BY page_view_dt;
...
```

This operation inserts data from `visits.customer_id` into `customer_visits.customer_id`, and from `visits.visit_num` into `customer_visits.visit_num`. These two columns are stored in generated ORC files. Simultaneously, values from `visits.page_view_dt` are used to create partitions for the partition column `customer_visits.page_view_dt`, which is not stored in the ORC files.

## Data modification in Hive

Hive is well-suited for reading large amounts of write-once data. Its optimal usage is loading data in bulk into tables and never modifying the data. In particular, for data stored in the ORC and Parquet formats, this usage pattern produces large, globally (or nearly globally) sorted files.

Periodic addition of data to tables (known as “trickle load”) is likely to produce many small files. The disadvantage of this is that Vertica has to access many more files during query planning and execution. These extra access can result in longer query-processing time. The major performance degradation comes from the increase in the number of file seeks on HDFS.

Hive can also modify underlying ORC or Parquet files without user involvement. If enough records in a Hive table are modified or deleted, for example, Hive deletes existing files and replaces them with newly-created ones. Hive can also be configured to automatically merge many small files into a few larger files.

When new tables are created, or existing tables are modified in Hive, you must manually synchronize Vertica to keep it up to date. The following statement synchronizes the Vertica schema “hcat” after a change in Hive:

```
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');
```

## Schema evolution in Hive

Hive supports two kinds of schema evolution:

1. New columns can be added to existing tables in Hive. Vertica automatically handles this kind of schema evolution. The old records display NULLs for the newer columns.
2. The type of a column for a table can be modified in Hive. Vertica does not support this kind of schema evolution.

The following example demonstrates schema evolution through new columns. In this example, `hcat.parquet.txt` is a file with the following values:

```
-1|0.65|0.65|6|'b'
```

```

hive> create table hcat.parquet_tmp (a int, b float, c double, d int, e varchar(4))
row format delimited fields terminated by '|' lines terminated by '\n';

hive> load data local inpath 'hcat.parquet.txt' overwrite into table
hcat.parquet_tmp;

hive> create table hcat.parquet_evolve (a int) partitioned by (f int) stored as
parquet;
hive> insert into table hcat.parquet_evolve partition (f=1) select a from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (b float);
hive> insert into table hcat.parquet_evolve partition (f=2) select a, b from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (c double);
hive> insert into table hcat.parquet_evolve partition (f=3) select a, b, c from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (d int);
hive> insert into table hcat.parquet_evolve partition (f=4) select a, b, c, d from
hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (e varchar(4));
hive> insert into table hcat.parquet_evolve partition (f=5) select a, b, c, d, e
from hcat.parquet_tmp;
hive> insert into table hcat.parquet_evolve partition (f=6) select a, b, c, d, e
from hcat.parquet_tmp;

=> SELECT * from hcat_local.parquet_evolve;

```

```

a | b | c | d | e | f
-----+-----+-----+-----+-----+-----
-1 | | | | | 1
-1 | 0.649999976158142 | | | | 2
-1 | 0.649999976158142 | 0.65 | | | 3
-1 | 0.649999976158142 | 0.65 | 6 | | 4
-1 | 0.649999976158142 | 0.65 | 6 | b | 5
-1 | 0.649999976158142 | 0.65 | 6 | b | 6
(6 rows)

```

## Apache Kafka integration

Vertica provides a high-performance mechanism for integrating with [Apache Kafka](#), an open-source distributed real-time streaming platform. Because Vertica can both consume data from and produce data for Kafka, you can use Vertica as part of an automated analytics workflow: Vertica can retrieve data from Kafka, perform analytics on the data, and then send the results back to Kafka for consumption by other applications.

### Prerequisites

- [Install Vertica](#).
- [Configure the database](#).
- Install and configure [Apache Kafka](#).

### Architecture overview

The Vertica and Kafka integration provides the following features:

- A UDX library containing functions that load and parse data from Kafka topics into Vertica
- A job scheduler that uses the UDL library to continuously consume data from Kafka with exactly-once semantics
- Push-based [notifiers](#) that send data collector messages from Vertica to Kafka
- A [KafkaExport](#) function that sends Vertica data to Kafka

## Vertica as a Kafka consumer

A Kafka consumer reads messages written to Kafka by other data streams. Because Vertica can read messages from Kafka, you can store and analyze data from any application that sends data to Kafka without configuring each individual application to connect to Vertica. Vertica provides tools to automatically or manually consume data loads from Kafka.

### Manual loads

Manually load a finite amount of data from Kafka by directly executing a COPY statement. This is useful if you want to analyze, test, or perform additional processing on a set of messages.

For more information, see [Consuming data from Kafka](#).

### Automatic loads

Automatically load data from Kafka with a job scheduler. A scheduler constantly loads data and ensures that each Kafka message is loaded exactly once.

You must install Java 8 on each Vertica node that runs the scheduler. For more information, see [Automatically consume data from Kafka with a scheduler](#).

## Vertica as a Kafka producer

A Kafka producer sends data to Kafka, which is then available to Kafka consumers for processing. You can send the following types of data to Kafka:

- Vertica analytics results. Use [KafkaExport](#) to export Vertica tables and queries.
- Health and performance data from [Data Collector](#) tables. Create push-based [notifiers](#) to send this data for consumption for third-party monitoring tools.
- Ad hoc messages. Use [NOTIFY](#) to signal that tasks such as stored procedures are complete.

For more information, see [Producing data for Kafka](#).

In this section

- [Data streaming schema tables](#)

## Data streaming integration terms

Vertica uses the following terms to describe its streaming feature. These are general terms, which may differ from each specific streaming platform's terminology.

## Terminology

### Host

A data streaming server.

### Source

A feed of messages in a common category which streams into the same Vertica target tables. In Apache Kafka, a source is known as a topic.

### Partition

Unit of parallelism within data streaming. Data streaming splits a source into multiple partitions, which can each be served in parallel to consumers such as a Vertica database. Within a partition, messages are usually ordered chronologically.

### Offset

An index into a partition. This index is the position within an ordered queue of messages, not an index into an opaque byte stream.

### Message

A unit of data within data streaming. The data is typically in JSON or Avro format. Messages are loaded as rows into Vertica tables, and are uniquely identified by their source, partition, and offset.

## Data loader terminology

### Scheduler

An external tool that schedules data loads from a streaming data source into Vertica.

### Microbatch

A microbatch represents a single segment of a data load from a streaming data source. It encompasses all of the information the scheduler needs to perform a load from a streaming data source into Vertica.

### Frame

The window of time during which a Scheduler executes microbatches to load data. This window controls the duration of each COPY statement the scheduler runs as a part of the microbatch. During the frame, the scheduler gives an active microbatch from each source an opportunity to load data. It gives priority to microbatches that need more time to load data based on the history of previous microbatches.

### Stream

A feed of messages that is identified by a source and partition.

The offset uniquely identifies the position within a particular source-partition stream.

### Lane

A thread within a job scheduler instance that issues microbatches to perform the load.

The number of lanes available is based on the PlannedConcurrency of the job scheduler's resource pool. Multiple lanes allow the scheduler to run microbatches for different sources in parallel during a frame.

## Configuring Vertica and Kafka

Both Vertica and Kafka have settings you can use to optimize your streaming data loads. The topics in this section explain these settings.

In this section

- [Kafka and Vertica configuration settings](#)
- [Directly setting Kafka library options](#)
- [Configuring Vertica for Apache Kafka version 0.9 and earlier](#)

## Kafka and Vertica configuration settings

You can fine-tune configuration settings for Vertica and Kafka that optimize performance.

The Vertica and Kafka integration uses rdkafka version 0.11.6. Unless otherwise noted, the following configuration settings use the default librdkafka configuration properties values. For instructions on how to override the default values, see [Directly setting Kafka library options](#).

### Vertica producer settings

These settings change how Vertica produces data for Kafka with the [KafkaExport](#) function and [notifiers](#).

#### **queue.buffering.max.messages**

Size of the Vertica producer queue. If Vertica generates too many messages too quickly, the queue can fill, resulting in dropped messages. Increasing this value consumes more memory, but reduces the chance of lost messages.

#### **Defaults :**

- KafkaExport: 1000
- Notifiers: 10000

### **queue.buffering.max.ms**

Frequency with which Vertica flushes the producer message queue. Lower values decrease latency at the cost of throughput. Higher values increase throughput, but can cause the producer queue (set by `queue.buffering.max.messages`) to fill more frequently, resulting in dropped messages.

**Default:** 100 ms

### **message.max.bytes**

Maximum size of a Kafka protocol request message batch. This value should be the same on your sources, brokers, and producers.

### **message.send.max.retries**

Number of attempts the producer makes to deliver the message to a broker. Higher values increase the chance of success.

### **retry.backoff.ms**

Interval Vertica waits before resending a failed message.

### **request.required.acks**

Number of broker replica acknowledgments Kafka requires before it considers message delivery successful. Requiring acknowledgments increases latency. Removing acknowledgments increases the risk of message loss.

### **request.timeout.ms**

Interval that the producer waits for a response from the broker. Broker response time is affected by server load and the number of message acknowledgments you require.

Higher values increase latency.

### **compression.type**

Compression algorithm used to encode data before sending it to a broker. Compression helps to reduce the network footprint of your Vertica producers and increase disk utilization. Vertica supports `gzip` and `snappy`.

## Kafka broker settings

Kafka brokers receive messages from producers and distribute them among Kafka consumers. Configure these settings on the brokers themselves. These settings function independently of your producer and consumer settings. For detailed information on Apache Kafka broker settings, refer to the [Apache Kafka documentation](#).

### **message.max.bytes**

Maximum size of a Kafka protocol request message batch. This value should be the same on your sources, brokers, and producers.

### **num.io.threads**

Number of network threads the broker uses to receive and process requests. More threads can increase your concurrency.

### **num.network.threads**

Number of network threads the broker uses to accept network requests. More threads can increase your concurrency.

## Vertica consumer settings

The following settings changes how Vertica acts when it consumes data from Kafka. You can set this value using the `kafka_conf` parameter on the KafkaSource UDL when directly executing a COPY statement. For schedulers, use the `--message_max_bytes` settings in the [scheduler tool](#).

### **message.max.bytes**

Maximum size of a Kafka protocol request message batch. Set this value to a high enough value to prevent the overhead of fetching batches of messages interfering with loading data. Defaults to 24MB for newly-created load specs.

## Directly setting Kafka library options

Vertica relies on the open source rdkafka library to communicate with Apache Kafka. This library contains many configuration properties that control how Vertica and Kafka interact. You set the most common rdkafka library properties through the settings in the [vkconfig utility](#) and the [Kafka integration functions](#).

There are some rdkafka properties that you cannot directly set from within the Vertica. Under normal circumstances, you do not need to change them. However, if you find that you need to set a specific rdkafka property that is not directly available from Vertica, you can set the property directly through one of the following options or parameters:

- `kafka_conf` : sets global configuration options. This is available as a vkconfig option and a function parameter.
- `kafka_topic_conf` : sets topic-level configuration options. This is available as a parameter in the [KafkaExport](#) and [KafkaSource](#) functions.
- `kafka_conf_secret` : sets options that accept sensitive information, such as passwords. This is available as a vkconfig option and a function parameter. Values passed to `kafka_conf_secret` are not logged or stored in system tables.

For a list of global and topic rdkafka configuration properties, see the [rdkafka repository on GitHub](#).

## Important

Arbitrarily setting configuration properties might result in errors or unpredictable behavior. If you encounter a problem loading messages after setting an rdkafka property using the configuration options that Vertica provides, roll back your change to see if that was the source of the problem.

To prevent confusion, never use one of the `kafka_*` options or parameters to set an rdkafka library property if you can set the property with an existing scheduler option. For example, do not use the `kafka_conf` option to set the Kafka `message.max.bytes` setting. Instead, use the [load-spec tool --message-max-bytes](#) option.

## Setting vkconfig properties

The `kafka_conf` option sets rdkafka properties when you [automatically consume data from Kafka](#) with the vkconfig scheduler. You can set its values in the following ways, listed in descending order of precedence:

1. The `--kafka_conf` option of the vkconfig utility. This option can be set in the [cluster](#), [source](#), [launch](#), and `sync` tools. Note that the setting only applies to each vkconfig utility call—it does not persist between calls and does not carry over to other vkconfig utility calls. For example, if you need to supply an option to the cluster and source tool, you must supply the `kafka_conf` option to both of them.
2. The Linux environment variable `VERTICA_RDKAFKA_CONF_KAFKA_CLUSTER` set on the host where you run the vkconfig utility. The `KAFKA_CLUSTER` portion of the variable name is the name of a Kafka cluster you have defined using vkconfig's [cluster utility](#). The settings in this environment variable only affect the specific Kafka cluster you name in `KAFKA_CLUSTER`.
3. The Linux environment variable `VERTICA_RDKAFKA_CONF` set on the host where you run the vkconfig utility.

### Note

Setting an rdkafka property with an environment variable helps to keep your settings consistent. It is easy to forget to set the `--kafka_conf` option for each call to the vkconfig script.

All of these options cascade, so setting an option using the `--kafka_conf` argument to the cluster tool overrides the same option that was set in the environment variables.

## Option and parameter formats

All `kafka_*` options and parameters accept a JSON string. You can pass configuration property settings in one of the following formats:

- One or more property/value pairs:

```
vkconfig scheduler option
--kafka_conf '{"option1":value1[, "option2":value2...]}'

function parameter
kafka_conf='{"option1":value1[, "option2":value2...}]'
```

- A single property with multiple values:

```
vkconfig scheduler option
--kafka_conf '{"option1":["value1[,value2...]}'
```

```
function parameter
kafka_conf='{"option1":["value1[,value2...}]'
```

## Examples

The following example demonstrates disabling rdkafka's `api.version.request` property when manually loading messages using KafkaSource. You should always disable this property when accessing Kafka cluster running version 0.9 or earlier. See [Configuring Vertica for Apache Kafka version 0.9 and earlier](#) for more information.

```

-> CREATE FLEX TABLE iot_data();
CREATE TABLE
-> COPY public.iot_data SOURCE KafkaSource(stream='iot_json|0|-2',
 brokers='kafka-01.example.com:9092',
 stop_on_eof=True,
 kafka_conf='{"api.version.request":false}')
 PARSER KafkaJSONParser();
Rows Loaded

 5000
(1 row)

```

This example demonstrates setting two properties with a JSON string when calling the cluster tool. It disables the `api.version.request` property and enables CRC checks of messages from Kafka using the `check.crcs` property:

```

$ vkconfig cluster --create --cluster StreamCluster1 \
 --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
 --conf myscheduler.config \
 --kafka_conf '{"api.version.request":false, "check.crcs":true}'

```

The following example demonstrates setting the same properties using an environment variable:

```

$ export VERTICA_RDKAFKA_CONF='{"api.version.request":false, "check.crcs":true}'
$ vkconfig cluster --create --cluster StreamCluster1 \
 --hosts kafka01.example.com:9092,kafka02.example.com:9092 \
 --conf myscheduler.config

```

**Important**  
 Setting the `check.crc` property is just an example. Vertica does not suggest you enable the CRC check in your schedulers under normal circumstances. It adds additional overhead and can result in slower performance.

### Configuring Vertica for Apache Kafka version 0.9 and earlier

Apache Kafka version 0.10 introduced a new feature that allows consumers to determine which version of the Kafka API the Kafka brokers support. Consumers that support this feature send an initial API version query to the Kafka broker to determine the API version to use when communicating with them. Kafka brokers running version 0.9.0 or earlier cannot respond to the API query. If the consumer does not receive a reply from the Kafka broker within a timeout period (set to 10 seconds by default) the consumer can assume the Kafka broker is running Kafka version 0.9.0 or earlier.

The Vertica integration with Kafka supports this API query feature starting in version 9.1.1. This API check can cause problems if you are connecting Vertica to a Kafka cluster running 0.9.0 or earlier. You may notice poorer performance loading messages from Kafka and may experience errors as the 10 second API request timeout can cause parts of the Kafka integration feature to time out and report errors.

For example, if you run the `vkconfig` source utility to configure a source on a Kafka 0.9 cluster, you may get the following error:

```
$ vkconfig source --create --conf weblog.conf --cluster kafka_weblog --source web_hits
Exception in thread "main" com.vertica.solutions.kafka.exception.ConfigurationException:

### Disabling the API version request when using the streaming job scheduler

To avoid these problems, you must disable the API version request feature in the rdafka library that Vertica uses to communicate with Kafka. The easiest way to disable this setting when using the scheduler is to set a Linux environment variable on the host on which you run the vkconfig script. Using the environment variable ensures that each call to vkconfig includes the setting to disable the API version request. The vkconfig script checks two variables:

- `VERTICA_RDKAFKA_CONF` applies to all Kafka clusters that the scheduler running on the host communicates with.
- `VERTICA_RDKAFKA_CONF_CLUSTER_NAME` applies to just the Kafka cluster named `CLUSTER_NAME`. Use this variable if your scheduler communicates with several Kafka clusters, some of which are not running version 0.9 or earlier.

If you set both variables, the cluster-specific one takes precedence. This feature is useful if most of the clusters your scheduler connects to are running Kafka 0.9 or earlier, but a few run 0.10 or later. This case, you can disable the API version check for most clusters using the `VERTICA_RDKAFKA_CONF` variable and re-enable the check for specific clusters using `VERTICA_RDKAFKA_CONF_CLUSTER_NAME`.

If just a few of your Kafka clusters run version 0.9 or earlier, you can just set the cluster-specific variables for them, and leave the default values in place for the majority of your clusters.

The contents of the environment variable is a JSON object that tells the rdafka library whether to query the Kafka cluster for the API version it supports:

```
{"api.version.request":false}'
```

To set the environment variable in BASH, use the export command:

```
$ export VERTICA_RDKAFKA_CONF='{"api.version.request":false}'
```

If you wanted the setting to just affect a cluster named `kafka_weblog`, the command is:

```
$ export VERTICA_RDKAFKA_CONF_kafka_weblog='{"api.version.request":false}'
```

You can add the command to any of the common user environment configuration files such as `~/.bash_profile` or the system-wide files such as `/etc/profile`. You must ensure that the same setting is used for all users who may run the vkconfig script, including any calls made by daemon processes such as `init`. You can also directly include this command in any script you use to set configure or start your scheduler.

### Disabling the API version request when directly loading messages

You can disable the API request when you directly call `KafkaSource` to load messages by using the `kafka_conf` parameter:

```
-> CREATE FLEX TABLE iot_data();
CREATE TABLE
-> COPY public.iot_data SOURCE KafkaSource(stream='iot_json101-2',
 brokers='kafka-01.example.com:9092',
 stop_on_eof=True,
 kafka_conf='{"api.version.request":false}')
 PARSE KafkaJSONParser();
Rows Loaded

 5000
(1 row)
```

## Vertica Eon Mode and Kafka

You can use the Vertica integration with Apache Kafka when Vertica is running in [Eon Mode](#). For Eon Mode running in a cloud environment, consider using a larger frame duration for schedulers in clusters. Cloud infrastructures lead to larger latencies overall, especially when storage layers are separated from compute layers. If you do not account for the added latency, you can experience a lower data throughput, as more of the frame's time is lost to overhead caused by the cloud environment. Using a longer frame length can also help prevent Vertica from creating many small ROS containers when loading data from Kafka. The trade off when you use a larger frame length is that your data load experiences more latency. See [Choosing a frame duration](#) for more information.

## Consuming data from Kafka

A Kafka consumer subscribes to one or more topics managed by a Kafka cluster. Each topic is a data stream, an unbounded dataset that is represented as an ordered sequence of messages. Vertica can manually or automatically consume Kafka topics to perform analytics on your streaming data.

### Manually consume data

Manually consume data from Kafka with a COPY statement that calls a KafkaSource function and parser. Manual loads are helpful when you want to:

- Populate a table one time with the messages currently in Kafka.
- Analyze a specific set of messages. You can choose the subset of data to load from the Kafka stream.
- Explore the data in a Kafka stream before you set up a scheduler to continuously stream the data into Vertica.
- Control the data load in ways not possible with the scheduler. For example, you cannot perform business logic or custom rejection handling during the data load from Kafka because the scheduler does not support additional processing during its transactions. Instead, you can periodically run a transaction that executes a COPY statement to load data from Kafka, and then perform additional processing.

For a detailed example, see [Manually consume data from Kafka](#).

### Automatically consume data

Automatically consume streaming data from Kafka into Vertica with a [scheduler](#), a command-line tool that loads data as it arrives. The scheduler loads data in segments defined by a microbatch, a unit of work that processes the partitions of a single Kafka topic for a specified duration of time. You can manage scheduler configuration and options using the [vkconfig tool](#).

For details, see [Automatically consume data from Kafka with a scheduler](#).

### Monitoring consumption

You must monitor message consumption to ensure that Kafka and Vertica are communicating effectively. You can use native Kafka tools to monitor consumer groups, or you can use [vkconfig tool](#) to view consumption details.

For additional information, see [Monitoring message consumption](#).

### Parsing data with Kafka filters

Your data stream might encode data that the Kafka parser functions cannot parse by default. Use Kafka filters to delimit messages in your stream to improve data consumption.

For details, see [Parsing custom formats](#).

In this section

- [Manually consume data from Kafka](#)
- [Automatically consume data from Kafka with a scheduler](#)
- [Monitoring message consumption](#)
- [Parsing custom formats](#)

## Manually consume data from Kafka

You can manually load streaming data from Kafka into Vertica using a [COPY](#) statement, just as you can load a finite set of data from a file or other source. Unlike a standard data source, Kafka data arrives continuously as a stream of messages that you must parse before loading into Vertica. Use [Kafka functions](#) in the COPY statement to prepare the data stream.

This example incrementally builds a COPY statement that manually loads JSON-encoded data from a Kafka topic named `web_hits`. The `web_hits` topic streams server logs of web site requests.

For information about loading data into Vertica, see [Data load](#).

### Creating the target table

To determine the target table schema, you must identify the message structure. The following is a sample of the `web_hits` stream:

```
{ "url": "list.jsp", "ip": "144.177.38.106", "date": "2017/05/02 20:56:00",
 "user-agent": "Mozilla/5.0 (compatible; MSIE 6.0; Windows NT 6.0; Trident/5.1)" }
{ "url": "search/wp-content.html", "ip": "215.141.172.28", "date": "2017/05/02 20:56:01",
 "user-agent": "Opera/9.53.(Windows NT 5.2; sl-SI) Presto/2.9.161 Version/10.00" }
```

This topic streams JSON-encoded data. Because JSON data is inconsistent and might contain unpredictable added values, store this data stream in a flex table. Flex tables dynamically accept additional fields that appear in the data.

The following statement creates a flex table named `web_table` to store the data stream:

```
=> CREATE FLEX TABLE web_table();
```

To begin the COPY statement, add the `web_table` as the target table:

```
COPY web_table
```

For more information about flex tables, see [Flex tables](#).

#### Note

If you are copying data containing default values into a flex table, you must identify the default value column as `__raw__`. For more information, see [Bulk Loading Data into Flex Tables](#).

## Defining KafkaSource

The source of your COPY statement is always [KafkaSource](#). `KafkaSource` accepts details about the data stream, Kafka brokers, and additional processing options to continuously load data until an [end condition](#) is met.

### Stream details

The stream parameter defines the data segment that you want to load from one or more topic partitions. Each Kafka topic splits its messages into different partitions to get scalable throughput. Kafka keeps a backlog of messages for each topic according to rules set by the Kafka administrator. You can choose to load some or all of the messages in the backlog, or just load the currently streamed messages.

For each partition, the stream parameter requires the topic name, topic partition, and the partition offset as a list delimited by a pipe character (`|`). Optionally, you can provide an end offset as an end condition to stop loading from the data stream:

```
'stream=' topic_name | partition | start_offset [| end_offset]
```

To load the entire backlog from a single partition of the `web_hits` topic, use the `SOURCE` keyword to append `KafkaSource` with the following `stream` parameter values:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2', ...
```

In the previous example:

- `web_hits` is the name of the topic to load data from.
- `0` is the topic partition to load data from. Topic partitions are 0-indexed, and `web_hits` contains only one partition.
- `-2` loads the entire backlog. This is a special offset value that tells `KafkaSource` to start loading at the earliest available message offset.

### Loading multiple partitions

This example loads from only one partition, but it is important to understand how to load from multiple partitions in a single `COPY` statement.

To load from additional partitions in the same topic, or even additional topics, supply a comma-separated list of topic name, partition number, and offset values delimited by pipe characters. For example, the following `stream` argument loads the entire message backlog from partitions 0 through 2 of the `web_hits` topic:

```
KafkaSource(stream='web_hits|0|-2,web_hits|1|-2,web_hits|2|-2'...
```

#### Note

While you can load messages from different Kafka topics in the same `COPY` statement, you must ensure the data from the different topics is compatible with the target table's schema. The schema is less of a concern if you are loading data into a flex table, which can accommodate almost any data you want to load.

When you load multiple partitions in the same `COPY` statement, you can set the `executionparallelism` parameter to define the number of threads created for the `COPY` statement. Ideally, you want to use one thread per partition. You can choose to not specify a value and let Vertica determine the number of threads based on the number of partitions and the resources available in the resource pool. In this example, there is only one partition, so there's no need for additional threads to load data.

#### Note

The `EXECUTIONPARALLELISM` setting on the resource pool assigned is the upper limit on the number of threads your `COPY` statement can use. Setting `executionparallelism` on the `KafkaSource` function call to a value that is higher than that of the resource pool's `EXECUTIONPARALLELISM` setting does not increase the number of threads Vertica uses beyond the limits of the resource pool.

### Adding the Kafka brokers

`KafkaSource` requires the host names (or IP addresses) and port numbers of the brokers in your Kafka cluster. The Kafka brokers are the service Vertica accesses in order to retrieve the Kafka data. In this example, the Kafka cluster has one broker named `kafka01.example.com`, running on port 9092. Append the `brokers` parameter and value to the `COPY` statement:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2',
 brokers='kafka01.example.com:9092', ...
```

### Choosing the end condition

Because data continuously arrives from Kafka, manual loads from Kafka require that you define an end condition that indicates when to stop loading data. In addition to the end offset described in [Stream Details](#), you can choose to:

- Copy as much data as possible for a set duration of time.
- Load data until no new data arrives within a timeout period.
- Load all available data, and not wait for any further data to arrive.

This example runs `COPY` for 10000 milliseconds (10 seconds) to get a sample of the data. If the `COPY` statement is able to load the entire backlog of data in under 10 seconds, it spends the remaining time loading streaming data as it arrives. This value is set in the `duration` parameter. Append the `duration` value to complete the `KafkaSource` definition:

```
COPY ...
SOURCE KafkaSource(stream='web_hits|0|-2',
 brokers='kafka01.example.com:9092',
 duration=interval '10000 milliseconds')
```

If you start a long-duration `COPY` statement from Kafka and need to stop it, you can call one of the functions that closes its session, such as [CLOSE\\_ALL\\_SESSIONS](#).

### Important

The duration that you set for your data load is not exact. The duration controls how long the `KafkaSource` process runs.

## Selecting a parser

Kafka does not enforce message formatting on its data streams. Messages are often in Avro or JSON format, but they could be in any format. Your COPY statement usually uses one of three Kafka-specific parsers:

- [KafkaParser](#)
- [KafkaJSONParser](#)
- [KafkaAvroParser](#)

Because the Kafka parsers can recognize record boundaries in streaming data, the other parsers (such as the [Flex parsers](#)) are not directly compatible with the output of KafkaSource. You must alter the KafkaSource output using filters before other parsers can process the data. See [Parsing custom formats](#) for more information.

In this example, the data in the web\_hits is encoded in JSON format, so it uses the KafkaJSONParser. This value is set in the COPY statement's PARSE clause:

```
COPY ...
SOURCE ...
PARSER KafkaJSONParser()
```

## Storing rejected data

Vertica saves raw Kafka messages that the parser cannot parse to a rejects table, along with information on why it was rejected. This table is created by the COPY statement. This example saves rejects to the table named web\_hits\_rejections. This value is set in the COPY statement's REJECTED DATA AS TABLE clause:

```
COPY ...
SOURCE ...
PARSER ...
REJECTED DATA AS TABLE public.web_hits_rejections;
```

## Loading the data stream into Vertica

The following steps load JSON data from the web\_hits topic for 10 seconds using the COPY statement that was incrementally built in the previous sections:

1. Execute the COPY statement:

```
=> COPY web_table
 SOURCE KafkaSource(stream='web_hits|0|-2',
 brokers='kafka01.example.com:9092',
 duration=interval '10000 milliseconds')
 PARSER KafkaJSONParser()
 REJECTED DATA AS TABLE public.web_hits_rejections;
Rows Loaded

 800
(1 row)
```

2. Compute the flex table keys:

```
=> SELECT compute_flextable_keys('web_table');
 compute_flextable_keys

Please see public.web_table_keys for updated keys
(1 row)
```

For additional details, see [Computing flex table keys](#).

3. Query web\_table\_keys to return the keys:

```
=> SELECT * FROM web_table_keys;
key_name | frequency | data_type_guess
-----+-----+-----
date | 800 | Timestamp
user_agent | 800 | Varchar(294)
ip | 800 | Varchar(30)
url | 800 | Varchar(88)
(4 rows)
```

4. Query web\_table to return the data loaded from the web\_hits Kafka topic:

```
=> SELECT date, url, ip FROM web_table LIMIT 10;
 date | url | ip
-----+-----+-----

### Automatically consume data from Kafka with a scheduler

Vertica offers a scheduler that loads streamed messages from one or more Kafka topics. Automatically loading streaming data has a number of advantages over manually using COPY:

- The streamed data automatically appears in your database. The frequency with which new data appears in your database is governed by the scheduler's frame duration.
- The scheduler provides an exactly-once consumption process. The schedulers manage offsets for you so that each message sent by Kafka is consumed once.
- You can configure backup schedulers to provide high-availability. Should the primary scheduler fail for some reason, the backup scheduler automatically takes over loading data.
- The scheduler manages resources for the data load. You control its resource usage through the settings on the resource pool you assign to it. When loading manually, you must take into account the resources your load consumes.

There are a few drawbacks to using a scheduler which may make it unsuitable for your needs. You may find that schedulers do not offer the flexibility you need for your load process. For example, schedulers cannot perform business logic during the load transaction. If you need to perform this sort of processing, you are better off creating your own load process. This process would periodically run COPY statements to load data from Kafka. Then it would perform the business logic processing you need before committing the transaction.

For information on job scheduler requirements, refer to [Apache Kafka integrations](#).

### What the job scheduler does

The scheduler is responsible for scheduling loads of data from Kafka. The scheduler's basic unit of processing is a frame, which is a period of time. Within each frame, the scheduler assigns a slice of time for each active microbatch to run. Each microbatch is responsible for loading data from a single source. Once the frame ends, the scheduler starts the next frame. The scheduler continues this process until you stop it.

### The anatomy of a scheduler

Each scheduler has several groups of settings, each of which control an aspect of the data load. These groups are:

- The scheduler itself, which defines the configuration schema, frame duration, and resource pool.
- Clusters, which define the hosts in the Kafka cluster that the scheduler contacts to load data. Each scheduler can contain multiple clusters, allowing you to load data from multiple Kafka clusters with a single scheduler.
- Sources, which define the Kafka topics and partitions in those topics to read data from.
- Targets, which define the tables in Vertica that will receive the data. These tables can be traditional Vertica database tables, or they can be flex tables.
- Load specs, which define setting Vertica uses while loading the data. These settings include the parsers and filters Vertica needs to use to load the data. For example, if you are reading a Kafka topic that is in Avro format, your load spec needs to specify the Avro parser and schema.
- Microbatches, which represent an individual segment of a data load from a Kafka stream. They combine the definitions for your cluster, source, target, and load spec that you create using the other vkconfig tools. The scheduler uses all of the information in the microbatch to execute [COPY](#) statements using the [KafkaSource](#) UDL function to transfer data from Kafka to Vertica. The statistics on each microbatch's load is stored in the [stream\\_microbatch\\_history](#) table.

### The vkconfig script

You use a Linux command-line script named vkconfig to create, configure, and run schedulers. This script is installed on your Vertica hosts along with the Vertica server in the following path:

```
/opt/vertica/packages/kafka/bin/vkconfig
```

## Note

You can install and use the vkconfig utility on a non-Vertica host. You may want to do this if:

- You do not want the scheduler to use Vertica host resources.
- You want users who do not have shell accounts on the Vertica hosts to be able to set up and alter schedulers.

The easiest way to install vkconfig on a host is to install the Vertica server RPM. You must use the RPM that matches the version of Vertica installed on your database cluster. Do not create a database after installing the RPM. The vkconfig utility and its associated files will be in the `/opt/vertica/packages/kafka/bin` directory on the host.

The vkconfig script contains multiple tools. The first argument to the vkconfig script is always the tool you want to use. Each tool performs one function, such as changing one group of settings (such as clusters or sources) or starting and stopping the scheduler. For example, to create or configure a scheduler, you use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler other options...
```

### What happens when you create a scheduler

When you create a new scheduler, the vkconfig script takes the following steps:

- Creates a new Vertica schema using the name you specified for the scheduler. You use this name to identify the scheduler during configuration.
- Creates the tables needed to manage the Kafka data load in the newly-created schema. See [Data streaming schema tables](#) for more information.

### Validating schedulers

When you create or configure a scheduler, it validates the following settings:

- Confirms that all brokers in the specified cluster exist.
- Connects to the specified host or hosts and retrieves the list of all brokers in the Kafka cluster. Getting this list always ensures that the scheduler has an up-to-date list of all the brokers. If the host is part of a cluster that has already been defined, the scheduler cancels the configuration.
- Confirms that the specified source exists. If the source no longer exists, the source is disabled.
- Retrieves the number of partitions in the source. If the number of partitions retrieved from the source is different than the partitions value saved by the scheduler, Vertica updates the scheduler with the number of partitions retrieved from the source in the cluster.

You can disable validation using the `--validation-type` option in the vkconfig script's scheduler tool. See [Scheduler tool options](#) for more information.

### Synchronizing schedulers

By default, the scheduler automatically synchronizes its configuration and source information with Kafka host clusters. You can configure the synchronization interval using the `--config-refresh` scheduler utility option. Each interval, the scheduler:

- Checks for updates to the scheduler's configuration by querying its settings in its Vertica configuration schema.
- Performs all of the checks listed in [Validating Schedulers](#).

You can configure synchronization settings using the `--auto-sync` option using the vkconfig script's scheduler tool. [Scheduler tool options](#) for details.

### Launching a scheduler

You use the vkconfig script's launch tool to launch a scheduler.

When you launch a scheduler, it collects data from your sources, starting at the specified offset. You can view the [stream\\_microbatch\\_history](#) table to see what the scheduler is doing at any given time.

To learn how to create, configure, and launch a scheduler, see [Setting up a scheduler](#) in this guide.

You can also choose to bypass the scheduler. For example, you might want to do a single load with a specific range of offsets. For more information, see [Manually consume data from Kafka](#) in this guide.

If the Vertica cluster goes down, the scheduler attempts to reconnect and fails. You must relaunch the scheduler when the cluster is restarted.

### Managing a running scheduler

When you launch a scheduler from the command line, it runs in the foreground. It will run until you kill it (or the host shuts down). Usually, you want to start the scheduler as a daemon process that starts it when the host operating system starts, or after the Vertica database has started.

You shut down a running scheduler using the vkconfig script's shutdown tool. See [Shutdown tool options](#) for details.

You can change most of a scheduler's settings (adding or altering clusters, sources, targets, and microbatches for example) while it is running. The scheduler automatically acts on the configuration updates.

### Launching multiple job schedulers for high availability

For high availability, you can launch two or more identical schedulers that target the same configuration schema. You differentiate the schedulers using the launch tool's `--instance-name` option (see [Launch tool options](#)).

The active scheduler loads data and maintains an [S lock](#) on the [stream\\_lock](#) table. The scheduler not in use remains in stand-by mode until the active scheduler fails or is disabled. If the active scheduler fails, the backup scheduler immediately obtains the lock on the `stream_lock` table, and takes over loading data from Kafka where the failed scheduler left off.

### Managing messages rejected during automatic loads

Vertica rejects messages during automatic loads using the parser definition, which is required in the [microbatch load spec](#).

The scheduler creates a rejection table to store rejected messages for each microbatch automatically. To manually specify a rejection table, use the `--rejection-schema` and `--rejection-table` [microbatch utility options](#) when creating the microbatch. Query the [stream\\_microbatches](#) table to return the rejection schema and table for a microbatch.

For additional details about how Vertica handles rejected data, see [Handling messy data](#).

### Passing options to the scheduler's JVM

The scheduler uses a Java Virtual Machine to connect to Vertica via JDBC. You can pass command-line options to the JVM through a Linux environment variable named `VKCONFIG_JVM_OPTS`. This option is useful when configuring a scheduler to use TLS/SSL encryption when connecting to Vertica. See [Configuring your scheduler for TLS connections](#) for more information.

### Viewing schedulers from the MC

You can view the status of Kafka jobs from the MC. For more information, refer to [Viewing load history](#).

### Setting up a scheduler

#### Note

This document describes how to create and launch a scheduler in a Linux environment. For details about creating a containerized scheduler, see [Containerized Kafka Scheduler](#).

You set up a scheduler using the Linux command line. Usually you perform the configuration on the host where you want your scheduler to run. It can be one of your Vertica hosts, or a separate host where you have installed the `vkconfig` utility (see [The vkconfig Script](#) for more information).

The steps to launch a scheduler are explained in the following sections. These sections will use the example of loading web log data (hits on a web site) from Kafka into a Vertica table.

#### Create a config file (optional)

Many of the arguments you supply to the `vkconfig` script while creating a scheduler do not change. For example, you often need to pass a username and password to Vertica to authorize the changes to be made in the database. Adding the username and password to each call to `vkconfig` is tedious and error-prone.

Instead, you can pass the `vkconfig` utility a configuration file using the `--conf` option that specifies these arguments for you. It can save you a lot of typing and frustration.

The config file is a text file with a `keyword = value` pair on each line. Each keyword is a `vkconfig` command-line option, such as the ones listed in [Common vkconfig script options](#).

The following example shows a config file named `weblog.conf` that will be used to define a scheduler named `weblog_sched`. This config file is used throughout the rest of this example.

```
The configuraton options for the weblog_sched scheduler.
username=dbadmin
password=myspassword
dbhost=vertica01.example.com
dbport=5433
config-schema=weblog_sched
```

Add the vkconfig directory to your path (optional)

The vkconfig script is located in the `/opt/vertica/packages/kafka/bin` directory. Typing this path for each call to vkconfig is tedious. You can add vkconfig to your search path for your current Linux session using the following command:

```
$ export PATH=/opt/vertica/packages/kafka/bin:$PATH
```

For the rest of your session, you are able to call vkconfig without specifying its entire path:

```
$ vkconfig
Invalid tool
Valid options are scheduler, cluster, source, target, load-spec, microbatch, sync, launch,
shutdown, help
```

If you want to make this setting permanent, add the export statement to your `~/.profile` file. The rest of this example assumes that you have added this directory to your shell's search path.

Create a resource pool for your scheduler

Vertica recommends that you always create a [resource pool](#) specifically for each scheduler. Schedulers assume that they have exclusive use of their assigned resource pool. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools with [CREATE RESOURCE POOL](#).

The following [resource pool settings](#) play an important role when creating your scheduler's resource pool:

- `PLANNEDCONCURRENCY` determines the number of microbatches (COPY statements) that the scheduler sends to Vertica simultaneously.
- `EXECUTIONPARALLELISM` determines the maximum number of threads that each node creates to process a microbatch's partitions.
- `QUEUETIMEOUT` provides manual control over resource timings. Set this to 0 to allow the scheduler to manage timings.

See [Managing scheduler resources and performance](#) for detailed information about these settings and how to fine-tune a resource pool for your scheduler.

The following CREATE RESOURCE POOL statement creates a resource pool that loads 1 microbatch and processes 1 partition:

```
=> CREATE RESOURCE POOL weblog_pool
 MEMORYSIZE '10%'
 PLANNEDCONCURRENCY 1
 EXECUTIONPARALLELISM 1
 QUEUETIMEOUT 0;
```

If you do not create and assign a resource pool for your scheduler, it uses a portion of the GENERAL resource pool. Vertica recommends that you do not use the GENERAL pool for schedulers in production environments. This fallback to the GENERAL pool is intended as a convenience when you test your scheduler configuration. When you are ready to deploy your scheduler, create a resource pool that you tuned to its specific needs. Each time that you start a scheduler that is using the GENERAL pool, the vkconfig utility displays a warning message.

Not allocating enough resources to your schedulers can result in errors. For example, you might get `OVERSHOT DEADLINE FOR FRAME` errors if the scheduler is unable to load data from all topics in a data frame.

See [Resource pool architecture](#) for more information about resource pools.

Create the scheduler

Vertica includes a default scheduler named `stream_config`. You can use this scheduler or create a new scheduler using the vkconfig script's [scheduler tool](#) with the `--create` and `--config-schema` options:

```
$ vkconfig scheduler --create --config-schema scheduler_name --conf conf_file
```

The `--create` and `--config-schema` options are the only ones required to add a scheduler with default options. This command creates a new schema in Vertica that holds the scheduler's configuration. See [What Happens When You Create a Scheduler](#) for details on the creation of the scheduler's schema.

You can use additional configuration parameters to further customize your scheduler. See [Scheduler tool options](#) for more information.

The following example:

- Creates a scheduler named `weblog_sched` using the `--config-schema` option.
- Grants privileges to configure and run the scheduler to the Vertica user named `kafka_user` with the `--operator` option. The `dbadmin` user must specify additional privileges separately.
- Specifies a frame duration of seven minutes with the `--frame-duration` option. For more information about picking a frame duration, see [Choosing a frame duration](#).
- Sets the resource pool that the scheduler uses to the `weblog_pool` created earlier:

```
$ vkconfig scheduler --create --config-schema weblog_sched --operator kafka_user \
--frame-duration '00:07:00' --resource-pool weblog_pool --conf weblog.conf
```

#### Note

Technically, the previous example doesn't need to supply the `--config-schema` argument because it is set in the `weblog.conf` file. It appears in this example for clarity. There's no harm in supplying it on the command line as well as in the configuration file, as long as the values match. If they do not match, the value given on the command line takes priority.

#### Create a cluster

You must associate at least one Kafka cluster with your scheduler. Schedulers can access more than one Kafka cluster. To create a cluster, you supply a name for the cluster and host names and ports the Kafka cluster's brokers.

When you create a cluster, the scheduler attempts to validate it by connecting to the Kafka cluster. If it successfully connects, the scheduler automatically retrieves the list of all brokers in the cluster. Therefore, you do not have to list every single broker in the `--hosts` parameter.

The following example creates a cluster named `kafka_weblog`, with two Kafka broker hosts: `kafka01` and `kafka03` in the `example.com` domain. The Kafka brokers are running on port 9092.

```
$ vkconfig cluster --create --cluster kafka_weblog \
--hosts kafka01.example.com:9092,kafka03.example.com:9092 --conf weblog.conf
```

See [Cluster tool options](#) for more information.

#### Create a source

Next, create at least one source for your scheduler to read. The source defines the Kafka topic the scheduler loads data from as well as the number of partitions the topic contains.

To create and associate a source with a configured scheduler, use the `source` tool. When you create a source, Vertica connects to the Kafka cluster to verify that the topic exists. So, before you create the source, make sure that the topic already exists in your Kafka cluster. Because Vertica verifies the existence of the topic, you must supply the previously-defined cluster name using the `--cluster` option.

The following example creates a source for the Kafka topic named `web_hits` on the cluster created in the previous step. This topic has a single partition.

```
$ vkconfig source --create --cluster kafka_weblog --source web_hits --partitions 1 --conf weblog.conf
```

#### Note

The `--partitions` parameter is the number of partitions to load, not a list of individual partitions. For example, if you set this parameter to 3, the scheduler will load data from partitions 0, 1, and 2.

See [Source tool options](#) for more information.

#### Create a data table

Before you can create a target for your scheduler, you must create a target table in your Vertica database. This is the table Vertica uses to store the data the scheduler loads from Kafka. You must decide which type of table to create for your target:

- A standard Vertica database table, which you create using the `CREATE TABLE` statement. This type of table stores data efficiently. However, you must ensure that its columns match the data format of the messages in Kafka topic you are loading. You cannot load complex types of data into a standard Vertica table.

- A flex table, which you create using [CREATE FLEXIBLE TABLE](#). A flex table is less efficient than a standard Vertica database table. However, it is flexible enough to deal with data whose schema varies and changes. It also can load most complex data types that (such as maps and lists) that standard Vertica tables cannot.

Important  
Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before it is loaded by the scheduler.

The data in this example is in a set format, so the best table to use is a standard Vertica table. The following example creates a table named `web_hits` to hold four columns of data. This table is located in the public schema.

```
=> CREATE TABLE web_hits (ip VARCHAR(16), url VARCHAR(256), date DATETIME, user_agent VARCHAR(1024));
```

**Note**  
You do not need to create a rejection table to store rejected messages. The scheduler creates the rejection table automatically.

### Create a target

Once you have created your target table, you can create your scheduler's target. The target tells your scheduler where to store the data it retrieves from Kafka. This table must exist when you create your target. You use the `vkconfig` script's target tool with the `--target-schema` and `--target_table` options to specify the Vertica target table's schema and name. The following example adds a target for the table created in the previous step.

```
$ vkconfig target --create --target-schema public --target-table web_hits --conf weblog.conf
```

See [Target tool options](#) for more information.

### Create a load spec

The scheduler's load spec provides parameters that Vertica uses when parsing the data loaded from Kafka. The most important option is `--parser` which sets the parser that Vertica uses to parse the data. You have three parser options:

- [KafkaAvroParser](#) for data in Avro format.
- [KafkaJSONParser](#) for data in JSON format.
- [KafkaParser](#) to load each message into a single VARCHAR field. See [Parsing custom formats](#) for more information.

In this example, the data being loaded from Kafka is in JSON format. The following command creates a load spec named `weblog_load` and sets the parser to `KafkaJSONParser`.

```
$ vkconfig load-spec --create --parser KafkaJSONParser --load-spec weblog_load --conf weblog.conf
```

See [Load spec tool options](#) for more information.

### Create a microbatch

The microbatch combines all of the settings added to the scheduler so far to define the individual COPY statements that the scheduler uses to load data from Kafka.

The following example uses all of the settings created in the previous examples to create a microbatch called `weblog`.

```
$ vkconfig microbatch --create --microbatch weblog --target-schema public --target-table web_hits \
 --add-source web_hits --add-source-cluster kafka_weblog --load-spec weblog_load \
 --conf weblog.conf
```

For microbatches that might benefit from a reduced transaction size, consider using the `--max-parallelism` option when creating the microbatch. This option splits a single microbatch with multiple partitions into the specified number of simultaneous COPY statements consisting of fewer partitions.

See [Microbatch tool options](#) for more information about `--max-parallelism` and other options.

### Launch the scheduler

Once you've created at least one microbatch, you can run your scheduler. You start your scheduler using the launch tool, passing it the name of the scheduler's schema. The scheduler begins scheduling microbatch loads for every enabled microbatch defined in its schema.

The following example launches the `weblog` scheduler defined in the previous steps. It uses the `nohup` command to prevent the scheduler being killed when the user logs out, and redirects stdout and stderr to prevent a `nohup.out` file from being created.

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

Important  
Vertica does not recommend specifying a password on the command line. Passwords on the command line can be exposed by the system's list of processes, which shows the command line for each process. Instead, put the password in a configuration file. Make sure the configuration file's permissions only allow it to be read by the user.

See [Launch tool options](#) for more information.

### Checking that the scheduler is running

Once you have launched your scheduler, you can verify that it is running by querying the [stream\\_microbatch\\_history](#) table in the scheduler's schema. This table lists the results of each microbatch the scheduler has run.

For example, this query lists the microbatch name, the start and end times of the microbatch, the start and end offset of the batch, and why the batch ended. The results are ordered to start from when the scheduler was launched:

```
=> SELECT microbatch, batch_start, batch_end, start_offset,
 end_offset, end_reason
 FROM weblog_sched.stream_microbatch_history
 ORDER BY batch_start DESC LIMIT 10;
```

microbatch	batch_start	batch_end	start_offset	end_offset	end_reason

### Choosing a frame duration

One key setting for your scheduler is its frame duration. The duration sets the amount of time the scheduler has to run all of the microbatches you have defined for it. This setting has significant impact on how data is loaded from Apache Kafka.

### What happens during each frame

To understand the right frame duration, you first need to understand what happens during each frame.

The frame duration is split among the microbatches you add to your scheduler. In addition, there is some overhead in each frame that takes some time away from processing the microbatches. Within each microbatch, there is also some overhead which reduces the time the microbatch spends loading data from Kafka. The following diagram shows roughly how each frame is divided:

As you can see, only a portion of the time in the frame is spent actually loading the streaming data.

### How the scheduler prioritizes microbatches

To start with, the scheduler evenly divides the time in the frame among the microbatches. It then runs each microbatch in turn.

In each microbatch, the bulk of the time is dedicated to loading data using a [COPY](#) statement. This statement loads data using the [KafkaSource](#) UDL. It runs until one of two conditions occurs:

- It reaches the ends of the data streams for the topics and partitions you defined for the microbatch. In this case, the microbatch completes processing early.
- It reaches a timeout set by the scheduler.

As the scheduler processes frames, it notes which microbatches finish early. It then schedules them to run first in the next frame. Arranging the microbatches in this manner lets the scheduler allocate more of the time in the frame to the microbatches that are spending the most time loading data (and perhaps have not had enough time to reach the end of their data streams).

For example, consider the following diagram. During the first frame, the scheduler evenly divides the time between the microbatches. Microbatch #2 uses all of the time allocated to it (as indicated by the filled-in area), while the other microbatches do not. In the next frame, the scheduler rearranges the microbatches so that microbatches that finished early go first. It also allocates less time to the microbatches that ran for a shorter period. Assuming these microbatches finish early again, the scheduler is able to give the rest of the time in the frame to microbatch #2. This shifting of priorities continues while the scheduler runs. If one topic sees a spike in traffic, the scheduler compensates by giving the microbatch reading from that topic more time.

What happens if the frame duration is too short

If you make the scheduler's frame duration too short, microbatches may not have enough time to load all of the data in the data streams they are responsible for reading. In the worst case, a microbatch could fall further behind when reading a high-volume topic during each frame. If left unaddressed, this issue could result in messages never being loaded, as they age out of the data stream before the microbatch has a chance to read them.

In extreme cases, the scheduler may not be able to run each microbatch during each frame. This problem can occur if the frame duration is so short that much of it is spent in overhead tasks such as committing data and preparing to run microbatches. The COPY statement that each microbatch runs to load data from Kafka has a minimum duration of 1 second. Add to this the overhead of processing data loads. In general, if the frame duration is shorter than 2 seconds times the number of microbatches in the scheduler, then some microbatches may not get a chance to run in each frame.

If the scheduler runs out of time during a frame to run each microbatch, it compensates during the next frame by giving priority to the microbatches that didn't run in the prior frame. This strategy makes sure each microbatch gets a chance to load data. However, it cannot address the root cause of the problem. Your best solution is to increase the frame duration to give each microbatch enough time to load data during each frame.

What happens if the frame duration is too long

One downside of a long frame duration is increased data latency. This latency is the time between when Kafka sends data out and when that data becomes available for queries in your database. A longer frame duration means that there is more time between each execution of a microbatch. That translates into more time between the data in your database being updated.

Depending on your application, this latency may not be important. When determining your frame duration, consider whether having the data potentially delayed up to the entire length of the frame duration will cause an issue.

Another issue to consider when using a long frame duration is the time it takes to shut down the scheduler. The scheduler does not shut down until the current COPY statement completes. Depending on the length of your frame duration, this process might take a few minutes.

The minimum frame duration

At a minimum, allocate two seconds for each microbatch you add to your scheduler. The vkconfig utility warns you if your frame duration is shorter than this lower limit. In most cases, you want your frame duration to be longer. Two seconds per microbatch leaves little time for data to actually load.

Balancing frame duration requirements

To determine the best frame duration for your deployment, consider how sensitive you are to data latency. If you are not performing time-sensitive queries against the data streaming in from Kafka, you can afford to have the default 5 minute or even longer frame duration. If you need a shorter data latency, then consider the volume of data being read from Kafka. High volumes of data, or data that has significant spikes in traffic can cause problems if you have a short frame duration.

Using different schedulers for different needs

Suppose you are loading streaming data from a few Kafka topics that you want to query with low latency and other topics that have a high volume but which you can afford more latency. Choosing a "middle of the road" frame duration in this situation may not meet either need. A better solution is to use multiple schedulers: create one scheduler with a shorter frame duration that reads just the topics that you need to query with low latency. Then create another scheduler that has a longer frame duration to load data from the high-volume topics.

For example, suppose you are loading streaming data from an Internet of Things (IOT) sensor network via Kafka into Vertica. You use the most of this data to periodically generate reports and update dashboard displays. Neither of these use cases are particularly time sensitive. However, three of the topics you are loading from do contain time-sensitive data (system failures, intrusion detection, and loss of connectivity) that must trigger immediate alerts.

In this case, you can create one scheduler with a frame duration of 5 minutes or more to read most of the topics that contain the non-critical data. Then create a second scheduler with a frame duration of at least 6 seconds (but preferably longer) that loads just the data from the three time-sensitive topics. The volume of data in these topics is hopefully low enough that having a short frame duration will not cause problems.

### Managing scheduler resources and performance

Your scheduler's performance is impacted by the number of [microbatches](#) in your scheduler, partitions in each microbatch, and nodes in your Vertica cluster. Use resource pools to allocate a subset of system resources for your scheduler, and fine-tune those resources to optimize automatic loads into Vertica.

The following sections provide details about scheduler resource pool configurations and processing scenarios.

### Schedulers and resource pools

Vertica recommends that you always create a [resource pool](#) specifically for each scheduler. Schedulers assume that they have exclusive use of their assigned resource pool. Using a separate pool for a scheduler lets you fine-tune its impact on your Vertica cluster's performance. You create resource pools with [CREATE RESOURCE POOL](#).

If you do not create and assign a resource pool for your scheduler, it uses a portion of the GENERAL resource pool. Vertica recommends that you do not use the GENERAL pool for schedulers in production environments. This fallback to the GENERAL pool is intended as a convenience when you test your scheduler configuration. When you are ready to deploy your scheduler, create a resource pool that you tuned to its specific needs. Each time that you start a scheduler that is using the GENERAL pool, the vkconfig utility displays a warning message.

Not allocating enough resources to your schedulers can result in errors. For example, you might get OVERSHOT DEADLINE FOR FRAME errors if the scheduler is unable to load data from all topics in a data frame.

See [Resource pool architecture](#) for more information about resource pools.

### Key resource pool settings

A microbatch is a unit of work that processes the partitions of a single Kafka topic within the [duration of a frame](#). The following [resource pool settings](#) play an important role in how Vertica loads microbatches and processes partitions:

- **PLANNEDCONCURRENCY** determines the number of microbatches (COPY statements) the scheduler sends to Vertica simultaneously. At the start of each frame, the scheduler creates the number of scheduler threads specified by PLANNEDCONCURRENCY. Each scheduler thread connects to Vertica and loads one microbatch at a time. If there are more microbatches than scheduler threads, the scheduler queues the extra microbatches and loads them as threads become available.
- **EXECUTIONPARALLELISM** determines the maximum number of threads each node creates to process a microbatch's partitions. When a microbatch is loaded into Vertica, its partitions are distributed evenly among the nodes in the cluster. During each frame, a node creates a maximum of one thread for each partition. Each thread reads from one partition at a time until processing completes, or the frame ends. If there are more partitions than threads across all nodes, remaining partitions are processed as threads become available.
- **QUEUETIMEOUT** provides manual control over resource timings. Set the resource pool parameter QUEUETIMEOUT to 0 to allow the scheduler to manage timings. After all of the microbatches are processed, the scheduler waits for the remainder of the frame to process the next microbatch. A properly sized configuration includes rest time to plan for traffic surges. See [Choosing a frame duration](#) for information about the impacts of frame duration size.

For example, the following CREATE RESOURCE POOL statement creates a resource pool named weblogs\_pool that loads 2 microbatches simultaneously. Each node in the Vertica cluster creates 10 threads per microbatch to process partitions:

```
=> CREATE RESOURCE POOL weblogs_pool
 MEMORYSIZE '10%'
 PLANNEDCONCURRENCY 2
 EXECUTIONPARALLELISM 10
 QUEUETIMEOUT 0;
```

For a three-node Vertica cluster, weblogs\_pool provides resources for each node to create up to 10 threads to process partitions, or 30 total threads per microbatch.

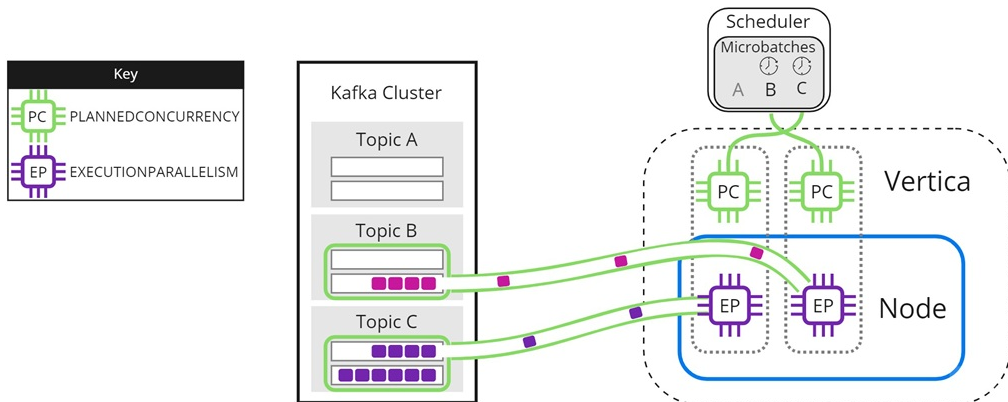

## Loading multiple microbatches concurrently

In some circumstances, you might have more microbatches in your scheduler than available [PLANNEDCONCURRENCY](#). The following images illustrate how the scheduler loads microbatches into a single Vertica node when there are not enough scheduler threads to load each microbatch simultaneously. The resource pool's `PLANNEDCONCURRENCY` (PC) is set to 2, but the scheduler must load three microbatches: A, B, and C. For simplicity, `EXECUTIONPARALLELISM` (EP) is set to 1.

To begin, the scheduler loads microbatch A and microbatch B while microbatch C waits:

When either microbatch finishes loading, the scheduler loads any remaining microbatches. In the following image, microbatch A is completely loaded into Vertica. The scheduler continues to load microbatch B, and uses the newly available scheduler thread to load microbatch C:

The scheduler continues sending data until all microbatches are loaded into Vertica, or the frame ends.

Experiment with `PLANNEDCONCURRENCY` to optimize performance. Note that setting it too high might create too many connections at the beginning of each frame, resulting in scalability stress on Vertica or Kafka. Setting `PLANNEDCONCURRENCY` too low does not take full advantage of the multiprocessing power of Vertica.

## Parallel processing within Vertica

The resource pool setting [EXECUTIONPARALLELISM](#) limits the number of threads each Vertica node creates to process partitions. The following image illustrates how a three-node Vertica cluster processes a topic with nine partitions, when there is not enough `EXECUTIONPARALLELISM` to create one thread per partition. The partitions are distributed evenly among Node 1, Node 2, and Node 3 in the Vertica cluster. The scheduler's resource pool has `PLANNEDCONCURRENCY` (PC) set to 1 and `EXECUTIONPARALLELISM` (EP) set to 2, so each node creates a maximum of 2 threads when the scheduler loads microbatch A. Each thread reads from one partition at a time. Partitions that are not assigned a thread must wait for processing:

As threads finish processing their assigned partitions, the remaining partitions are distributed to threads as they become available:

When setting the EXECUTIONPARALLELISM on your scheduler's resource pool, consider the number of partitions across all microbatches in the scheduler.

#### Loading partitioned topics concurrently

Single topics with multiple partitions might benefit from increased parallel loading or a reduced transaction size. The `--max-parallelism` [microbatch utility option](#) enables you to dynamically split a topic with multiple partitions into multiple, load-balanced microbatches that each consist of a subset of the original microbatch's partitions. The scheduler loads the dynamically split microbatches simultaneously using the [PLANNEDCONCURRENCY](#) available in its resource pool.

The [EXECUTIONPARALLELISM](#) setting in the scheduler's resource pool determines the maximum number of threads each node creates to process its portion of a single microbatch's partitions. Splitting a microbatch enables each node to create more threads for the same unit of work. When there is enough [PLANNEDCONCURRENCY](#) and the number of partitions assigned per node is greater than the [EXECUTIONPARALLELISM](#) setting in the scheduler's resource pool, use `--max-parallelism` to split the microbatch and create more threads per node to process more partitions in parallel.

The following image illustrates how a two-node Vertica cluster loads and processes microbatch A using a resource pool with [PLANNEDCONCURRENCY](#) (PC) set to 2, and [EXECUTIONPARALLELISM](#) (EP) set to 2. Because the scheduler is loading only one microbatch, there is 1 scheduler thread left unused. Each node creates 2 threads per scheduler thread to process its assigned partitions:

Setting microbatch A's `--max-parallelism` option to 2 enables the scheduler to dynamically split microbatch A into 2 smaller microbatches, A1 and A2. Because there are 2 available scheduler threads, the subset microbatches are loaded into Vertica simultaneously. Each node creates 2 threads per scheduler thread to process partitions for microbatches A1 and A2:

Use `--max-parallelism` to prevent bottlenecks in microbatches consisting of high-volume Kafka topics. It also provides faster loads for microbatches that require additional processing, such as text indexing.

### Using connection load balancing with the Kafka scheduler

You supply the scheduler with the name of a Vertica node in the `--dbhost` option or the `dbhost` entry in your configuration file. The scheduler connects to this node to initiate all of the statements it executes to load data from Kafka. For example, each time it executes a microbatch, the scheduler connects to the same node to run the `COPY` statement. Having a single node act as the initiator node for all of the scheduler's actions can affect the performance of the node, and in turn the database as a whole.

To avoid a single node becoming a bottleneck, you can use connection load balancing to spread the load of running the scheduler's statements across multiple nodes in your database. Connection load balancing distributes client connections among the nodes in a load balancing group. See [About native connection load balancing](#) for an overview of this feature.

Enabling connection load balancing for a scheduler is a two-step process:

1. Choose or create a load balancing policy for your scheduler.
2. Enable load balancing in the scheduler.

### Choosing or creating a load balancing policy for the scheduler

A connecting load balancing policy redirects incoming connections in from a specific set of network addresses to a group of nodes. If your database already defines a suitable load balancing policy, you can use it instead of creating one specifically for your scheduler.

If your database does not have a suitable policy, create one. Have your policy redirect connections coming from the IP addresses of hosts running Kafka schedulers to a group of nodes in your database. The group of nodes that you select will act as the initiators for the statements that the scheduler executes.

### Important

In an [Eon Mode](#) database, only include nodes that are part of a [primary subcluster](#) in the scheduler's load balancing group. These nodes are the most efficient for loading data.

The following example demonstrates setting up a load balancing policy for all three nodes in a three-node database. The scheduler runs on node 1 in the database, so the source address range (192.168.110.0/24) of the routing rule covers the IP addresses of the nodes in the database. The last step of the example verifies that connections from the first node (IP address 10.20.110.21) are load balanced.

```
=> SELECT node_name,node_address,node_address_family FROM v_catalog.nodes;
node_name | node_address | node_address_family
```

```
-----+-----+-----
v_vmart_node0001 | 10.20.110.21 | ipv4
v_vmart_node0002 | 10.20.110.22 | ipv4
v_vmart_node0003 | 10.20.110.23 | ipv4
(4 rows)
```

```
=> CREATE NETWORK ADDRESS node01 ON v_vmart_node0001 WITH '10.20.110.21';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_vmart_node0002 WITH '10.20.110.22';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 on v_vmart_node0003 WITH '10.20.110.23';
CREATE NETWORK ADDRESS
```

```
=> CREATE LOAD BALANCE GROUP kafka_scheduler_group WITH ADDRESS node01,node02,node03;
CREATE LOAD BALANCE GROUP
=> CREATE ROUTING RULE kafka_scheduler_rule ROUTE
'10.20.110.0/24' TO kafka_scheduler_group;
CREATE ROUTING RULE
=> SELECT describe_load_balance_decision('10.20.110.21');
describe_load_balance_decision
```

```

Describing load balance decision for address [10.20.110.21]
Load balance cache internal version id (node-local): [2]
Considered rule [kafka_scheduler_rule] source ip filter [10.20.110.0/24]...
input address matches this rule
Matched to load balance group [kafka_scheduler_group] the group has policy [ROUNDROBIN]
number of addresses [3]
(0) LB Address: [10.20.110.21]:5433
(1) LB Address: [10.20.110.22]:5433
(2) LB Address: [10.20.110.23]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.20.110.23] port [5433]
```

```
(1 row)
```

### Important

Be careful if you run your scheduler on a Vertica node and have either set its dbhost name to localhost or are not specifying a value (which means dbhost defaults to localhost). Connections to localhost use the loopback IP address 127.0.0.1 instead of the node's primary network address. If you create a load balancing routing rule that redirects incoming connections from the node's IP address range, it will not apply to connections made using localhost. The best solution is to use the node's IP address or FQDN as the dbhost setting.

If your scheduler connects to Vertica from an IP address that no routing rule applies to, you will see messages similar to the following in the vertica.log:

```
[Session] <INFO> Load balance request from client address ::1 had decision:
Classic load balancing considered, but either the policy was NONE or no target was
available. Details: [NONE or invalid]
<LOG> @v_vmart_node0001: 00000/5789: Connection load balance request
refused by server
```

## Enabling load balancing in the scheduler

Clients must opt-in to load balancing for Vertica to apply the connection load balancing policies to the connection. For example, you must pass the `-C` flag to the `vsq` command for your interactive session to be load balanced.

The scheduler uses the Java JDBC library to connect to Vertica. To have the scheduler opt-in to load balancing, you must set the JDBC library's `ConnectionLoadBalance` option to 1. See [Load balancing in JDBC](#) for details.

Use the `vkconfig` script's `--jdbc-opt` option, or add the `jdbc-opt` option to your configuration file to set the `ConnectionLoadBalance` option. For example, to start the scheduler from the command line using a configuration file named `weblog.conf`, use the command:

```
$ nohup vkconfig launch --conf weblog.conf --jdbc-opt ConnectionLoadBalance=1 >/dev/null 2>&1 &
```

To permanently enable load balancing, you can add the load balancing option to your configuration file. The following example shows the `weblog.conf` file from the example in [Setting up a scheduler](#) configured to use connection load balancing.

```
username=dbadmin
password=mypassword
dbhost=10.20.110.21
dbport=5433
config-schema=weblog_sched
jdbc-opt=ConnectionLoadBalance=1
```

You can check whether the scheduler's connections are being load balanced by querying the [SESSIONS](#) table:

```
=> SELECT node_name, user_name, client_label FROM V_MONITOR.SESSIONS;
 node_name | user_name | client_label
-----+-----+-----
v_vmart_node0001 | dbadmin | vkstream_weblog_sched_leader_persistent_4
v_vmart_node0001 | dbadmin |
v_vmart_node0002 | dbadmin | vkstream_weblog_sched_lane-worker-0_0_8
v_vmart_node0003 | dbadmin | vkstream_weblog_sched_VDBLogger_0_9
(4 rows)
```

In the `client_labels` column, the scheduler's connections have labels starting with `vkstream` (the row without a client label is an interactive session). You can see that the three connections the scheduler has opened all go to different nodes.

## Limiting loads using offsets

Kafka maintains a user-configurable backlog of messages. By default, a newly-created scheduler reads all of the messages in a Kafka topic, including all of the messages in the backlog, not just the messages that are streamed out after the scheduler starts. Often, this is what you want.

In some cases, however, you may want to stream just a section of a source into a table. For example, suppose you want to analyze the web traffic of your e-commerce site starting at specific date and time. However, your Kafka topic contains web access records from much further back in time than you want to analyze. In this case, you can use an offset to stream just the data you want into Vertica for analysis.

Another common use case is when you have already loaded data some from Kafka manually (see [Manually consume data from Kafka](#)). Now you want to stream all of the newly-arriving data. By default, your scheduler will reload all of the previously loaded data (assuming it is still available from Kafka). You can use an offset to tell your scheduler to start automatically loading data at the point where your manual data load left off.

## Configuring a scheduler to start streaming from an offset

The `vkconfig` script's `microbatch` tool has an `--offset` option that lets you specify the index of the message in the source where you want the scheduler to begin loading. This option accepts a comma-separated list of index values. You must supply one index value for each partition in the source unless you use the `--partition` option. This option lets you choose the partitions the offsets apply to. The scheduler cannot be running when you set an offset in the `microbatch`.

If your `microbatch` defines more than one cluster, use the `--cluster` option to select which one the offset option applies to. Similarly, if your `microbatch` has more than one source, you must select one using the `--source` option.

For example, suppose you want to load just the last 1000 messages from a source named `web_hits`. To make things easy, suppose the source contains just a single partition, and the `microbatch` defines just a single cluster and single topic.

Your first task is to determine the current offset of the end of the stream. You can do this on one of the Kafka nodes by calling the `GetOffsetShell` class with the `time` parameter set to `-1` (the end of the topic):

```
$ path to kafka/bin/kafka-run-class.sh kafka.tools.GetOffsetShell \
 --broker-list kafka01:9092,kafka03:9092 --time -1 \
 --topic web_hits

{metadata.broker.list=kafka01:9092,kafka03:9092, request.timeout.ms=1000,
client.id=GetOffsetShell, security.protocol=PLAINTEXT}
web_hits:0:8932
```

You can also use `GetOffsetShell` to find the offset in the stream that occurs before a timestamp.

In the above example, the `web_hits` topic's single partition has an ending offset of 8932. If we want to load the last 1000 messages from the source, we need to set the microbatch's offset to  $8932 - 1001$  or 7931.

#### Note

The start of an offset is inclusive in the Vertica `COPY` statement. Kafka's native starting offset is exclusive. Therefore, you must add one to the offset to get the correct number of messages.

With the offset calculated, you are ready to set it in the microbatch's configuration. The following example:

- Shuts down the scheduler whose configuration information stored in the `weblog.conf` file.
- Sets the starting offset using the microbatch utility.
- Restarts the scheduler.

```
$ vkconfig shutdown --conf weblog.conf
$ vkconfig microbatch --microbatch weblog --update --conf weblog.conf --offset 7931
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

If the target table was empty or truncated before the scheduler started, it will have 1000 rows in the table in it (until more messages are streamed through the source):

```
=> select count(*) from web_hits;
count

1000
(1 row)
```

#### Note

The last example assumes that the offset values for the last 1000 messages in the Kafka topic were assigned consecutively. This assumption is not always true. A Kafka topic can have gaps in its offset numbering for a variety of reasons. Offsets refer to the key value assigned to a message by Kafka, not its position in the topic.

### Updating schedulers after Vertica upgrades

A scheduler is only compatible with the version of Vertica that created it. Between Vertica versions, the scheduler's configuration schema or the UDX function the scheduler calls may change. After you upgrade Vertica, you must update your schedulers to account for these changes.

When you upgrade Vertica to a new major version or service pack, use the `vkconfig` scheduler tool's `--upgrade` option to update your scheduler. If you do not update a scheduler, you receive an error message if you try to launch it. For example:

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
com.vertica.solutions.kafka.exception.FatalException: Configured scheduler schema and current
scheduler configuration schema version do not match. Upgrade configuration by running:
vkconfig scheduler --upgrade
 at com.vertica.solutions.kafka.scheduler.StreamCoordinator.assertVersion(StreamCoordinator.java:64)
 at com.vertica.solutions.kafka.scheduler.StreamCoordinator.run(StreamCoordinator.java:125)
 at com.vertica.solutions.kafka.Launcher.run(Launcher.java:205)
 at com.vertica.solutions.kafka.Launcher.main(Launcher.java:258)
Scheduler instance failed. Check log file. Check log file.
$ vkconfig scheduler --upgrade --conf weblog.conf
Checking if UPGRADE necessary...
UPGRADE required, running UPGRADE...
UPGRADE completed successfully, now the scheduler configuration schema version is v8.1.1
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
. . .
```

## Monitoring message consumption

You can monitor the progress of your data streaming from Kafka several ways:

- Monitoring the consumer groups to which Vertica reports its progress. This technique is best if the tools you want to use to monitor your data load work with Kafka.
- Use the monitoring APIs built into the vkconfig tool. These APIs report the configuration and consumption of your streaming scheduler in JSON format. These APIs are useful if you are developing your own monitoring scripts, or your monitoring tools can consume status information in JSON format.

In this section

- [Monitoring Vertica message consumption with consumer groups](#)
- [Getting configuration and statistics information from vkconfig](#)

## Monitoring Vertica message consumption with consumer groups

Apache Kafka has a feature named consumer groups that helps distribute message consumption loads across sets of consumers. When using consumer groups, Kafka evenly divides up messages based on the number of consumers in the group. Consumers report back to the Kafka broker which messages it read successfully. This reporting helps Kafka to manage message offsets in the topic's partitions, so that no consumer in the group is sent the same message twice.

Vertica does not rely on Kafka's consumer groups to manage load distribution or preventing duplicate loads of messages. The streaming job scheduler manages topic partition offsets on its own.

Even though Vertica does not need consumer groups to manage offsets, it does report back to the Kafka brokers which messages it consumed. This feature lets you use third-party tools to monitor the Vertica cluster's progress as it loads messages. By default, Vertica reports its progress to a consumer group named `vertica- databaseName`, where `databaseName` is the name of the Vertica database. You can change the name of the consumer group that Vertica reports its progress to when defining a scheduler or during manual loads of data. Third party tools can query the Kafka brokers to monitor the Vertica cluster's progress when loading data.

For example, you can use Kafka's `kafka-consumer-groups.sh` script (located in the `bin` directory of your Kafka installation) to view the status of the Vertica consumer group. The following example demonstrates listing the consumer groups available defined in the Kafka cluster and showing the details of the Vertica consumer group:

```
$ cd /path/to/kafka/bin
$./kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

```
vertica-vmart
$./kafka-consumer-groups.sh --describe --group vertica-vmart \
 --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

Consumer group 'vertica-vmart' has no active members.

TOPIC	PARTITION	CURRENT-OFFSET	LOG-END-OFFSET	LAG	CONSUMER-ID	HOST
CLIENT-ID						
web_hits	0	24500	30000	5500	-	-

From the output, you can see that Vertica reports its consumption of messages back to the vertica-vmart consumer group. This group is the default consumer group when Vertica has the example VMart database loaded. The second command lists the topics being consumed by the vertica-vmart consumer group. You can see that the Vertica cluster has read 24500 of the 30000 messages in the topic's only partition. Later, running the same command will show the Vertica cluster's progress:

```
$ cd /path/to/kafka/bin
$./kafka-consumer-groups.sh --describe --group vertica-vmart \
 --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

Consumer group 'vertica-vmart' has no active members.

TOPIC	PARTITION	CURRENT-OFFSET	LOG-END-OFFSET	LAG	CONSUMER-ID	HOST
CLIENT-ID						
web_hits	0	30000	30000	0	-	-

Changing the consumer group where Vertica reports its progress

You can change the consumer group that Vertica reports its progress to when consuming messages.

Changing for automatic loads with the scheduler

When using a scheduler, you set the consumer group by setting the `--consumer-group-id` argument to the vkconfig script's [scheduler](#) or [microbatch](#) utilities. For example, suppose you want the example scheduler shown in [Setting up a scheduler](#) to report its consumption to the consumer group name vertica-database. Then you could use the command:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update \
 --conf weblog.conf --microbatch weblog --consumer-group-id vertica-database
```

When the scheduler begins loading data, it will start updating the new consumer group. You can see this on a Kafka node using `kafka-consumer-groups.sh`.

Use the `--list` option to return the consumer groups:

```
$ /path/to/kafka/bin/kafka-consumer-groups.sh --list --bootstrap-server localhost:9092
Note: This will not show information about old Zookeeper-based consumers.
```

```
vertica-database
vertica-vmart
```

Use the `--describe` and `--group` options to return details about a specific consumer group:

```
$ /path/to/kafka/bin/kafka-consumer-groups.sh --describe --group vertica-database \
--bootstrap-server localhost:9092
```

Note: This will not show information about old Zookeeper-based consumers.

Consumer group 'vertica-database' has no active members.

TOPIC	PARTITION	CURRENT-OFFSET	LOG-END-OFFSET	LAG	CONSUMER-ID	HOST
CLIENT-ID						
web_hits	0	30300	30300	0	-	-

Changing for manual loads

To change the consumer group when manually loading data, use the `group_id` parameter of `KafkaSource` function:

```
=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
 brokers='kafka01.example.com:9092',
 stop_on_eof=True,
 group_id='vertica_database')
 PARSER KafkaJSONParser();
```

Rows Loaded

```

50000
(1 row)
```

Using consumer group offsets when loading messages

You can choose to have your scheduler, manual load, or custom loading script start loading messages from the consumer group's offset. To load messages from the last offset stored in the consumer group, use the special `-3` offset.

Automatic load with the scheduler example

To instruct your scheduler to load messages from the consumer group's saved offset, use the `vkconfig` script [microbatch tool's --offset](#) argument.

1. Stop the scheduler using the shutdown command and the configuration file that you used to create the scheduler:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch shutdown --conf weblog.conf
```

2. Set the `microbatch --offset` option to `-3`:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --update --conf weblog.conf --microbatch weblog --offset -3
```

This sets the offset to `-3` for all topic partitions that your scheduler reads from. The scheduler begins the next load with the consumer group's saved offset, and all subsequent loads use the offset saved in [stream\\_microbatch\\_history](#).

Manual load example

This example loads messages from the `web_hits` topic that has one partition consisting of 51,000 messages. For details about manual loads with `KafkaSource`, see [Manually consume data from Kafka](#).

1. The first `COPY` statement creates a consumer group named `vertica_manual`, and loads the first 50,000 messages from the first partition in the `web_hits` topic:

```
=> COPY web_hits
SOURCE KafkaSource(stream='web_hits|0|50000',
 brokers='kafka01.example.com:9092',
 stop_on_eof=True,
 group_id='vertica_manual')
PARSER KafkaJSONParser()
REJECTED DATA AS TABLE public.web_hits_rejections;
```

Rows Loaded

```

50000
(1 row)
```

2. The next `COPY` statement passes `-3` as the `start_offset` stream parameter to load from the consumer group's saved offset:

```

=> COPY web_hits
SOURCE KafkaSource(stream='web_hits|0|-3',
 brokers='kafka01.example.com:9092',
 stop_on_eof=True,
 group_id='vertica_manual')
PARSER KafkaJSONParser()
REJECTED DATA AS TABLE public.web_hits_rejections;
Rows Loaded

 1000
(1 row)

```

### Disabling consumer group reporting

Vertica reports the offsets of the messages it consumes to Kafka by default. If you do not specifically configure a consumer group for Vertica, it still reports its offsets to a consumer group named `vertica_<database-name>` (where `database-name` is the name of the database Vertica is currently running).

If you want to completely disable having Vertica report its consumption back to Kafka, you can set the consumer group to an empty string or NULL. For example:

```

=> COPY web_hits SOURCE KafkaSource(stream='web_hits|0|-2',
 brokers='kafka01.example.com:9092',
 stop_on_eof=True,
 group_id=NULL)
PARSER KafkaJsonParser();
Rows Loaded

 60000
(1 row)

```

### Getting configuration and statistics information from vkconfig

The `vkconfig` tool has two features that help you examine your scheduler's configuration and monitor your data load:

- The `vkconfig` tools that configure your scheduler (scheduler, cluster, source, target, load-spec, and microbatch) have a `--read` argument that has them output their current settings in the scheduler.
- The `vkconfig` statistics tool lets you get statistics on your microbatches. You can filter the microbatch records based on a date and time range, cluster, partition, and other criteria.

Both of these features output their data in JSON format. You can use third-party tools that can consume JSON data or write your own scripts to process the configuration and statics data.

You can also access the data provided by these `vkconfig` options by querying the configuration tables in the scheduler's schema. However, you may find these options easier to use as they do not require you to connect to the Vertica database.

### Getting configuration information

You pass the `--read` option to `vkconfig`'s configuration tools to get the current settings for the options that the tool can set. This output is in JSON format. This example demonstrates getting the configuration information from the scheduler and cluster tools for the scheduler defined in the `weblog.conf` configuration file:

```

$ vkconfig scheduler --read --conf weblog.conf
{"version":"v9.2.0", "frame_duration":"00:00:10", "resource_pool":"weblog_pool",
 "config_refresh":"00:05:00", "new_source_policy":"FAIR",
 "pushback_policy":"LINEAR", "pushback_max_count":5, "auto_sync":true,
 "consumer_group_id":null}

$ vkconfig cluster --read --conf weblog.conf
{"cluster":"kafka_weblog", "hosts":"kafak01.example.com:9092,kafka02.example.com:9092"}

```

The `--read` option lists all of values created by the tool in the scheduler schema. For example, if you have defined multiple targets in your scheduler, the `--read` option lists all of them.

```
$ vkconfig target --list --conf weblog.conf
{"target_schema":"public", "target_table":"health_data"}
{"target_schema":"public", "target_table":"iot_data"}
{"target_schema":"public", "target_table":"web_hits"}
```

You can filter the `--read` option output using the other arguments that the vkconfig tools accept. For example, in the cluster tool, you can use the `--host` argument to limit the output to just show clusters that contain a specific host. These arguments support LIKE-predicate wildcards, so you can match partial values. See [LIKE](#) for more information about using wildcards.

The following example demonstrates how you can filter the output of the `--read` option of the cluster tool using the `--host` argument. The first call shows the unfiltered output. The second call filters the output to show only those clusters that start with "kafka":

```
$ vkconfig cluster --read --conf weblog.conf
{"cluster":"some_cluster", "hosts":"host01.example.com"}
{"cluster":"iot_cluster",
 "hosts":"kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster":"weblog",
 "hosts":"web01.example.com.com:9092,web02.example.com:9092"}
{"cluster":"streamcluster1",
 "hosts":"kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}
{"cluster":"test_cluster",
 "hosts":"test01.example.com:9092,test02.example.com:9092"}

$ vkconfig cluster --read --conf weblog.conf --hosts kafka%
{"cluster":"iot_cluster",
 "hosts":"kafka-iot01.example.com:9092,kafka-iot02.example.com:9092"}
{"cluster":"streamcluster1",
 "hosts":"kafka-a-01.example.com:9092,kafka-a-02.example.com:9092"}
```

See the [Cluster tool options](#), [Load spec tool options](#), [Microbatch tool options](#), [Scheduler tool options](#), [Target tool options](#), and [Source tool options](#) for more information.

#### Getting streaming data load statistics

The vkconfig script's statistics tool lets you view the history of your scheduler's microbatches. You can filter the results using any combination of the following criteria:

- The name of the microbatch
- The Kafka cluster that was the source of the data load
- The name of the topic
- The partition within the topic
- The Vertica schema and table targeted by the data load
- A date and time range
- The latest microbatches

See [Statistics tool options](#) for all of the options available in this tool.

This example gets the last two microbatches that the scheduler ran:

```
$ vkconfig statistics --last 2 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,

```

See [Statistics tool options](#) for more examples of using this tool.

## Parsing custom formats

To process a Kafka data stream, the parser must identify the boundary between each message. Vertica provides Kafka parsers that can identify boundaries for [Avro](#), [JSON](#), and [raw data](#) formats, but your data stream might use a custom format. To parse custom formats, Vertica provides filters that insert boundary information in the data stream before it reaches the parser.

### Kafka filters

Vertica provides the following filters:

- `KafkaInsertDelimiters`: Inserts a user-specified delimiter between each message in the data stream. The delimiter can contain any characters and be of any length. This parser uses the following syntax:  
`KafkaInsertDelimiters(delimiter = ' delimiter')`
- `KafkaInsertLengths`: Inserts the message length in bytes at the beginning of the message. Vertica writes the length as a 4-byte uint32 value in big-endian network byte order. For example, a 100-byte message is preceded by 0x00000064. This parser uses the following syntax:  
`KafkaInsertLengths()`

### Note

Because each Kafka filter requires input from a stream source and outputs a non-stream source, you cannot use both Kafka filters in the same COPY statement to process a Kafka data stream.

In addition to one of the Kafka filters, you can include one or more user-defined filters in a single COPY statement. Specify multiple filters as a comma-separated list, and list the Vertica filter first. If you use a non-Kafka parser, you must use at least one filter to prepare the data stream for the parser, or the parser fails and returns an error.

### Examples

The following COPY statement loads comma-separated values from two partitions in a topic named `iot-data`. The load exits after it processes all messages in both partitions. The `KafkaInsertDelimiters` filter inserts newlines between the Kafka messages to convert them into traditional rows of data. The statement uses the standard COPY parser to delimit CSV values with a comma:

```
=> COPY kafka_iot SOURCE KafkaSource(stream='iot-data|0|-2,iot-data|1|-2',
 brokers='kafka01:9092',
 stop_on_eof=True)
 FILTER KafkaInsertDelimiters(delimiter = E'\n')
 DELIMITER ',';

Rows Loaded

 3430
(1 row)
```

## Avro Schema Registry

Vertica supports the use of a Confluent schema registry for Avro schemas with the [KafkaAvroParser](#). By using a schema registry, you enable the Avro parser to parse and decode messages written by the registry and to retrieve schemas stored in the registry. In addition, a schema registry enables Vertica to process streamed data without sending a copy of the schema with each record. Vertica can access a schema registry in the following ways:

- schema ID
- subject and version

### Note

If you use the compatibility config resource in your schema registry, you should specify a value of at least BACKWARD. You may also choose to use a stricter compatibility setting. For more information on installing and configuring a schema registry, refer to the [Confluent documentation](#).

### Schema ID Loading

In schema ID based loading, the Avro parser checks the schema ID associated with each message to identify the correct schema to use. A single COPY statement can reference multiple schemas. Because each message is not validated, Vertica recommends that you use a flex table as the target table for schema ID based loading.

The following example shows a COPY statement that refers to a schema registry located on the same host:

```
=> COPY logs source kafkasource(stream='simple|0|0', stop_on_eof=true,
duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://localhost:8081/');
```

### Subject and Version Loading

In subject and version loading, you specify a subject and version in addition to the schema registry URL. The addition of the subject and version identifies a single schema to use for all messages in the COPY. If any message in the statement is incompatible with the schema, the COPY fails. Because all messages are validated prior to loading, Vertica recommends that you use a standard Vertica table as the target for subject and version loading.

The following example shows a COPY statement that identifies a schema subject and schema version as well as a schema registry.

```
=> COPY t source kafkasource(stream='simpleEvolution|0|0',
stop_on_eof=true, duration=interval '10 seconds') parser
KafkaAvroParser(schema_registry_url='http://repository:8081/schema-repo',
schema_registry_subject='simpleEvolution-value', schema_registry_version='1')
REJECTED DATA AS TABLE 't_rejects';
```

## Producing data for Kafka

In addition to consuming data from Kafka, Vertica can produce data for Kafka. Stream the following data from Vertica for consumption by other Kafka consumers:

- Vertica analytics results. Use [KafkaExport](#) to export Vertica tables and queries.
- Health and performance data from [Data Collector](#) tables. Create push-based [notifiers](#) to send this data for consumption for third-party monitoring tools.
- Ad hoc messages. Use [NOTIFY](#) to signal that tasks such as stored procedures are complete.

In this section

- [Producing data using KafkaExport](#)
- [Producing Kafka messages using notifiers](#)

## Producing data using KafkaExport

The `KafkaExport` function lets you stream data from Vertica to Kafka. You pass this function three arguments and two or three parameters:

```
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
 USING PARAMETERS brokers='host[:port][.host...]',
 topic='topicname'
 [,kafka_conf='kafka_configuration_setting']
 [,kafka_topic_conf='kafka_configuration_setting']
 [,kafka_conf_secret='kafka_configuration_setting']
 [,fail_on_conf_parse_error=Boolean])
OVER (partition_clause) FROM table;
```

The *partitionColumn* and *keyColumn* arguments set the Kafka topic's partition and key value, respectively. You can set either or both of these values to NULL. If you set the partition to NULL, Kafka uses its default partitioning scheme (either randomly assigning partitions if the key value is NULL, or based on the key value if it is not).

The *valueColumn* argument is a LONG VARCHAR containing message data that you want to send to Kafka. Kafka does not impose structure on the message content. Your only restriction on the message format is what the consumers of the data are able to parse.

You are free to convert your data into a string in any way you like. For simple messages (such as a comma-separated list), you can use functions such as [CONCAT](#) to assemble your values into a message. If you need a more complex data format, such as JSON, consider writing a UDX function that accepts columns of data and outputs a LONG VARCHAR containing the data in the format you require. See [Developing user-defined extensions \(UDxs\)](#) for more information.

See [KafkaExport](#) for detailed information about `KafkaExport`'s syntax.

### Export example

This example shows you how to perform a simple export of several columns of a table. Suppose you have the following table containing a simple set of Internet of things (IOT) data:

```
=> SELECT * FROM iot_report LIMIT 10;
server | date | location | id
-----+-----+-----+-----
 1 | 2016-10-11 04:09:28 | -14.86058, 112.75848 | 70982027
 1 | 2017-07-02 12:37:48 | -21.42197, -127.17672 | 49494918
 1 | 2017-10-19 14:04:33 | -71.72156, -36.27381 | 94328189
 1 | 2018-07-11 19:35:18 | -9.41315, 102.36866 | 48366610
 1 | 2018-08-30 08:09:45 | 83.97962, 162.83848 | 967212
 2 | 2017-01-20 03:05:24 | 37.17372, 136.14026 | 36670100
 2 | 2017-07-29 11:38:37 | -38.99517, 171.72671 | 52049116
 2 | 2018-04-19 13:06:58 | 69.28989, 133.98275 | 36059026
 2 | 2018-08-28 01:09:51 | -59.71784, -144.97142 | 77310139
 2 | 2018-09-14 23:16:15 | 58.07275, 111.07354 | 4198109
```

(10 rows)

```
=> \d iot_report
```

List of Fields by Tables

Schema	Table	Column	Type	Size	Default	Not Null	Primary Key	Foreign Key
public	iot_report	server	int	8		f	f	
public	iot_report	date	timestamp	8		f	f	
public	iot_report	location	varchar(40)	40		f	f	
public	iot_report	id	int	8		f	f	

(4 rows)

You want to send the data in this table to a Kafka topic named `iot_results` for consumption by other applications. Looking at the data and the structure of the `iot_report`, you may decide the following:

- The `server` column is a good match for the partitions in `iot_report`. There are three partitions in the Kafka topic, and the values in `server` column are between 1 and 3. Suppose the partition column had a larger range of values (for example, between 1 and 100). Then you could use the modulo operator (%) to coerce the values into the same range as the number of partitions (`server % 3`). A complication with these values is that the values in the `server` are 1-based (the lowest value in the column is 1). Kafka's partition numbering scheme is zero-based. So, you must adjust the values in the `server` column by subtracting 1 from them.
- The `id` column can act as the key. This column has a data type of `INTEGER`. The `KafkaExport` function expects the key value to be a `VARCHAR`. Vertica does not automatically cast `INTEGER` values to `VARCHAR`, so you must explicitly cast the value in your function call.
- The consumers of the `iot_report` topic expect values in comma-separated format. You can combine the values from the `date` and `location` columns into a single `VARCHAR` using nested calls to the `CONCAT` function.

The final piece of information you need to know is the host names and port numbers of the brokers in your Kafka cluster. In this example, there are two brokers named `kafka01` and `kafka03`, running on port 6667 (the port that Hortonworks clusters use). Once you have all of this information, you are ready to export your data.

The following example shows how you might export the contents of `iot_report`:

```
=> SELECT KafkaExport(server - 1, id::VARCHAR,
CONCAT(CONCAT(date, ', '), location)
USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
partition | key | message | failure_reason
```

(0 rows)

`KafkaExport` returned 0 rows which means Vertica was able to send all of your data to Kafka without any errors.

Other things to note about the example:

- The `CONCAT` function automatically converts the `date` column's `DATETIME` value to a `VARCHAR` for you, so you do not need to explicitly cast it.
- Two nested `CONCAT` functions are necessary to concatenate the `date` field with a comma, and the resulting string with the `location` field.
- Adding a third column to the `message` field would require *two* additional `CONCAT` function calls (one to concatenate a comma after the `location` column, and one to concatenate the additional column's value). Using `CONCAT` becomes messy after just a few column's worth of data.

On the Kafka side, you will see whatever you sent as the `valueColumn` (third) argument of the `KafkaExport` function. In the above example, this is a CSV list. If you started a console consumer for `iot_results` topic before running the example query, you would see the following output when the query runs:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --topic iot_results --zookeeper localhost
```

```
2017-10-10 12:08:33, 78.84883, -137.56584
2017-12-06 16:50:57, -25.33024, -157.91389
2018-01-12 21:27:39, 82.34027, 116.66703
2018-08-19 00:02:18, 13.00436, 85.44815
2016-10-11 04:09:28, -14.86058, 112.75848
2017-07-02 12:37:48, -21.42197, -127.17672
2017-10-19 14:04:33, -71.72156, -36.27381
2018-07-11 19:35:18, -9.41315, 102.36866
2018-08-30 08:09:45, 83.97962, 162.83848
2017-01-20 03:05:24, 37.17372, 136.14026
2017-07-29 11:38:37, -38.99517, 171.72671
2018-04-19 13:06:58, 69.28989, 133.98275
2018-08-28 01:09:51, -59.71784, -144.97142
2018-09-14 23:16:15, 58.07275, 111.07354
```

KafkaExport's return value

KafkaExport outputs any rows that Kafka rejected. For example, suppose you forgot to adjust the partition column to be zero-based in the previous example. Then some of the rows exported to Kafka would specify a partition that does not exist. In this case, Kafka rejects these rows, and KafkaExport reports them in table format:

```
=> SELECT KafkaExport(server, id::VARCHAR,
 CONCAT(CONCAT(date, ' '), location)
 USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
 topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
partition | key | message | failure_reason
-----+-----+-----+-----
3 | 40492866 | 2017-10-10 12:08:33, 78.84883, -137.56584, | Local: Unknown partition
3 | 73846006 | 2017-12-06 16:50:57, -25.33024, -157.91389, | Local: Unknown partition
3 | 45020829 | 2018-01-12 21:27:39, 82.34027, 116.66703, | Local: Unknown partition
3 | 27462612 | 2018-08-19 00:02:18, 13.00436, 85.44815, | Local: Unknown partition
(4 rows)
```

#### Note

Another common reason for Kafka rejecting a row is that its message value is longer than Kafka's `message.max.bytes` setting.

You can capture this output by creating a table to hold the rejects. Then use an INSERT statement to insert KafkaExport's results:

```
=> CREATE TABLE export_rejects (partition INTEGER, key VARCHAR, message LONG VARCHAR, failure_reason VARCHAR);
CREATE TABLE
=> INSERT INTO export_rejects SELECT KafkaExport(server, id::VARCHAR,
 CONCAT(CONCAT(date, ' '), location)
 USING PARAMETERS brokers='kafka01:6667,kafka03:6667',
 topic='iot_results') OVER (PARTITION BEST) FROM iot_report;
OUTPUT

4
(1 row)
=> SELECT * FROM export_rejects;
partition | key | message | failure_reason
-----+-----+-----+-----
3 | 27462612 | 2018-08-19 00:02:18, 13.00436, 85.44815 | Local: Unknown partition
3 | 40492866 | 2017-10-10 12:08:33, 78.84883, -137.56584 | Local: Unknown partition
3 | 73846006 | 2017-12-06 16:50:57, -25.33024, -157.91389 | Local: Unknown partition
3 | 45020829 | 2018-01-12 21:27:39, 82.34027, 116.66703 | Local: Unknown partition
(4 rows)
```

Producing Kafka messages using notifiers

You can use notifiers to help you monitor your Vertica database using third-party Kafka-aware tools by producing messages to a Kafka topic. You can directly publish messages (for example, from a SQL script to indicate a long-running query has finished). Notifiers can also automatically send messages when a component in the data collector tables is updated.

In this section

- [Creating a Kafka notifier](#)
- [Sending individual messages via a Kafka notifier](#)
- [Monitoring DC tables with Kafka notifiers](#)

Creating a Kafka notifier

The following procedure creates a Kafka notifier. At a minimum, a notifier defines:

- A unique name.
- A message protocol. This is `kafka://` when sending messages to Kafka.
- The server to communicate with. For Kafka, this is the address and port number of a Kafka broker.
- The maximum message buffer size. If the queue of messages to be sent via the notifier exceed this limit, messages are dropped.

You create the notifier with [CREATE NOTIFIER](#). This example creates a notifier named `load_progress_notifier` that sends messages via the Kafka broker running on `kafka01.example.com` on port 9092:

```
=> CREATE NOTIFIER load_progress_notifier
ACTION 'kafka://kafka01.example.com:9092'
MAXMEMORYSIZE '10M';
```

While not required, it is best practice to create notifiers that use an encrypted connection. The following example creates a notifier that uses an encrypted connection and verifies the Kafka server's certificate with the provided [TLS configurations](#):

```
=> CREATE NOTIFIER encrypted_notifier
ACTION 'kafka://127.0.0.1:9092'
MAXMEMORYSIZE '10M'
TLS CONFIGURATION 'notifier_tls_config'
```

Follow this procedure to create or alter notifiers for Kafka endpoints that use SASL\_SSL. Note that you must repeat this procedure whenever you change the TLSMODE, certificates, or CA bundle for a given notifier.

1. [Create a TLS Configuration](#) with the desired TLS mode, certificate, and CA certificates.
2. Use CREATE or ALTER to disable the notifier and set the TLS Configuration:

```
=> ALTER NOTIFIER encrypted_notifier
DISABLE
TLS CONFIGURATION kafka_tls_config;
```

3. ALTER the notifier and set the proper rdkafka adapter parameters for SASL\_SSL:

```
=> ALTER NOTIFIER encrypted_notifier PARAMETERS
'sasl.username=user;sasl.password=password;sasl.mechanism=PLAIN;security.protocol=SASL_SSL';
```

4. Enable the notifier:

```
=> ALTER NOTIFIER encrypted_notifier ENABLE;
```

Sending individual messages via a Kafka notifier

You can send an individual message via a Kafka notifier using the [NOTIFY](#) function. This feature is useful for reporting the progress of SQL scripts such as ETL tasks to third-party reporting tools.

You pass this function three string values:

- The message to send.
- The name of the notifier to send the message.
- The Kafka topic to receive the message.

For example, suppose you want to send the message "Daily load finished" to the `vertica_notifications` topic of the Kafka cluster defined in the `load_progress_notifier` notifier created earlier. Then you could execute the following statement:

```
=> SELECT NOTIFY('Daily load finished.',
 'load_progress_notifier',
 'vertica_notifications');
NOTIFY

OK
(1 row)
```

The message the notifier sends to Kafka is in JSON format. You can see the resulting message by using the console consumer on a Kafka node. For example:

```
$ /opt/kafka/bin/kafka-console-consumer.sh --bootstrap-server localhost:9092 \
 --from-beginning \
 --topic vertica_notifications \
 --max-messages 1

{"_db":"vmart","_schema":"v_internal","_table":"dc_notifications",
"channel":"vertica_notifications","message":"Daily load finished.",
"node_name":"v_vmart_node0001","notifier":"load_progress_notifier",
"request_id":2,"session_id":"v_vmart_node0001-463079:0x4ba6f",
"statement_id":-1,"time":"2018-06-19 09:48:42.314181-04",
"transaction_id":45035996275565458,"user_id":45035996273704962,
"user_name":"dbadmin"}

Processed a total of 1 messages
```

#### Monitoring DC tables with Kafka notifiers

The Vertica [Data collector](#) (DC) tables monitor many different database functions. You can have a [notifier](#) automatically send a message to a Kafka endpoint when a DC component updates. You can query the [DATA\\_COLLECTOR](#) table to get a list of the DC components.

You configure the notifier to send DC component updates to Kafka using the function [SET\\_DATA\\_COLLECTOR\\_NOTIFY\\_POLICY](#).

To be notified of failed login attempts, you can create a notifier that sends a notification when the DC component [LoginFailures](#) updates. The [TLSMODE](#) 'verify-ca' verifies that the server's certificate is signed by a trusted CA.

```
=> CREATE NOTIFIER vertica_stats ACTION 'kafka://kafka01.example.com:9092' MAXMEMORYSIZE '10M' TLSMODE 'verify-ca';
CREATE NOTIFIER
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', true);
SET_DATA_COLLECTOR_NOTIFY_POLICY

SET
(1 row)
```

Like the messages sent via the NOTIFY function, the data sent to Kafka from the DC components is in JSON format. The previous example results in messages like the following being sent to the vertica\_notifications Kafka topic:

```
{"_db":"vmart","_schema":"v_internal","_table":"dc_login_failures",
"authentication_method":"Reject","client_authentication_name":"","
"client_hostname":"","client_label":"","client_os_user_name":"dbadmin",
"client_pid":481535,"client_version":"","database_name":"alice",
"effective_protocol":"3.8","node_name":"v_vmart_node0001",
"reason":"INVALID USER","requested_protocol":"3.8","ssl_client_fingerprint":"","
"time":"2018-06-19 14:51:22.437035-04","user_name":"alice"}
```

#### Viewing notification policies for a DC component

Use the [GET\\_DATA\\_COLLECTOR\\_NOTIFY\\_POLICY](#) function to list the policies set for a DC component.

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY

Notifiable; Notifier: vertica_stats; Channel: vertica_notifications
(1 row)
```

## Disabling a notification policy

You can call [SET\\_DATA\\_COLLECTOR\\_NOTIFY\\_POLICY](#) function with its fourth argument set to FALSE to disable a notification policy. The following example disables the notify policy for the LoginFailures component:

```
=> SELECT SET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures','vertica_stats', 'vertica_notifications', false);
SET_DATA_COLLECTOR_NOTIFY_POLICY
```

```

SET
(1 row)
```

```
=> SELECT GET_DATA_COLLECTOR_NOTIFY_POLICY('LoginFailures');
GET_DATA_COLLECTOR_NOTIFY_POLICY
```

```

Not notifiable;
(1 row)
```

## TLS/SSL encryption with Kafka

You can use TLS/SSL encryption between Vertica, your scheduler, and Kafka. This encryption prevents others from accessing the data that is sent between Kafka and Vertica. It can also verify the identity of all parties involved in data streaming, so no impostor can pose as your Vertica cluster or a Kafka broker.

### Note

Many people often confuse the terms TLS and SSL. SSL is an older encryption protocol that has been largely replaced with the newer and more secure TLS standard. However, many people still use the term SSL to refer to encryption between servers and applications, even when that encryption is actually TLS. For example, Java and Kafka use the term SSL exclusively, even when dealing with TLS. This document uses SSL/TLS and SSL interchangeably.

Some common cases where you want to use SSL encryption between Vertica and Kafka are:

- Your Vertica database and Kafka communicate over an insecure network. For example, suppose your Kafka cluster is located in a cloud service and your Vertica cluster is within your internal network. In this case, any data you read from Kafka travels over an insecure connection across the Internet.
- You are required by security policies, laws, or other requirements to encrypt all of your network traffic.

For more information about TLS/SSL encryption in Vertica, see [TLS protocol](#).

### Using TLS/SSL between the scheduler and Vertica

The scheduler connects to Vertica the same way other client applications do. There are two ways you can configure Vertica to use SSL/TLS authentication and encryption with clients:

- If Vertica is configured to use SSL/TLS server authentication, you can choose to have your scheduler confirm the identity of the Vertica server.
- If Vertica is configured to use mutual SSL/TLS authentication, you can configure your scheduler to identify itself to Vertica as well as have it verify the identity of the Vertica server. Depending on your database's configuration, the Vertica server may require your scheduler to use TLS when connecting. See [Client authentication with TLS](#) for more information.

For information on encrypted client connections with Vertica, refer to [TLS protocol](#).

The scheduler runs on a Java Virtual Machine (JVM) and uses JDBC to connect to Vertica. It acts like any other JDBC client when connecting to Vertica. To use TLS/SSL encryption for the scheduler's connection to Vertica, use the Java keystore and truststore mechanism to hold the keys and certificates the scheduler uses to identify itself and Vertica.

- The keystore contains your scheduler's private encryption key and its certificate (public key).
- The truststore contains CAs that you trust. If you enable authentication, the scheduler uses these CAs to verify the identity of the Vertica cluster it connects to. If one of the CAs in the trust store was used to sign the server's certificate, then the Scheduler knows it can trust the identity of the Vertica server.

You can pass options to the JVM that executes the scheduler through the Linux environment variable named VKCONFIG\_JVM\_OPTS. You add the parameters to this variable that alter the scheduler's JDBC settings (such as the truststore and keystore for the scheduler's JDBC connection). See [Step 2: Set the VKCONFIG\\_JVM\\_OPTS Environment Variable](#) for an example.

You can also use the `--jdbc-url` scheduler option to alter the JDBC configuration. See [Common vkconfig script options](#) for more information about the scheduler options and [JDBC connection properties](#) for more information about the properties they can alter.

## Using TLS/SSL between Vertica and Kafka

You can stream data from Kafka into Vertica two ways: manually using a [COPY](#) statement and the [KafkaSource](#) UD source function, or automatically using the scheduler.

To directly copy data from Kafka via an SSL connection, you set session variables containing an SSL key and certificate. When KafkaSource finds that you have set these variables, it uses the key and certificate to create a secure connection to Kafka. See [Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka](#) for details.

When automatically streaming data from Kafka to Vertica, you configure the scheduler the same way you do to use an SSL connection to Vertica. When the scheduler executes COPY statements to load data from Kafka, it uses its own keystore and truststore to create an SSL connection to Kafka.

To use an SSL connection when producing data from Vertica to Kafka, you set the same session variables you use when directly streaming data from Kafka via an SSL connection. The [KafkaExport](#) function uses these variables to establish a secure connection to Kafka.

### Note

[Notifiers](#) do not currently support using TLS/SSL connections.

See the [Apache Kafka documentation](#) for more information about [using SSL/TLS authentication with Kafka](#).

In this section

- [Planning TLS/SSL encryption between Vertica and Kafka](#)
- [Configuring your scheduler for TLS connections](#)
- [Using TLS/SSL when directly loading data from Kafka](#)
- [Configure Kafka for TLS/SSL](#)
- [Troubleshooting Kafka TLS/SSL connection issues](#)

## Planning TLS/SSL encryption between Vertica and Kafka

Some things to consider before you begin configuring TLS/SSL:

- Which connections between the scheduler, Vertica, and Kafka needs to be encrypted? In some cases, you may only need to enable encryption between Vertica and Kafka. This scenario is common when Vertica and the Kafka cluster are on different networks. For example, suppose Kafka is hosted in a cloud provider and Vertica is hosted in your internal network. Then the data must travel across the unsecured Internet between the two. However, if Vertica and the scheduler are both in your local network, you may decide that configuring them to use SSL/TLS is unnecessary. In other cases, you will want all parts of the system to be encrypted. For example, you want to encrypt all traffic when Kafka, Vertica, and the scheduler are all hosted in a cloud provider whose network may not be secure.
- Which connections between the scheduler, Vertica, and Kafka require trust? You can opt to have any of these connections fail if one system cannot verify the identity of another. See [Verifying Identities](#) below.
- Which CAs will you be using to sign each certificate? The simplest way to configure the scheduler, Kafka, and Vertica is to use the same CA to sign all of the certificates you will use when setting up TLS/SSL. Using the same root CA to sign the certificates requires you to be able to edit the configuration of Kafka, Vertica, and the scheduler. If you cannot use the same CA to sign all certificates, all truststores must contain the entire chain of CAs used to sign the certificates, all the way up to the root CA. Including the entire chain of trust ensures each system can verify each other's identities.

### Verifying identities

Your primary challenge when configuring TLS/SSL encryption between Vertica, the scheduler, and Kafka is making sure the scheduler, Kafka, and Vertica can all verify each other's identity. The most common problem people have encountered when setting up TLS/SSL encryption is ensuring the remote system can verify the authenticity of a system's certificate. The best way to prevent this problem is to ensure that the all systems have their certificates signed by a CA that all of the systems explicitly trust.

When a system attempts to start an encrypted connection with another system, it sends its certificate to the remote system. This certificate can be signed by one or more Certificate Authorities (CA) that help identify the system making the connection. These signatures form a "chain of trust." A certificate is signed by a CA. That CA, in turn, could have been signed by another CA, and so forth. Often, the chain ends with a CA (referred to as the root CA) from a well-known commercial provider of certificates, such as Comodo SSL or DigiCert, that are trusted by default on many platforms such as operating systems and web browsers.

If the remote system finds a CA in the chain that it trusts, it verifies the identity of the system making the connection, and the connection can continue. If the remote system cannot find the signature of a CA it trusts, it may block the connection, depending on its configuration. Systems can be configured to only allow connections from systems whose identity has been verified.

## Note

Verifying the identity of another system making a TLS/SSL connection is often referred to as "authentication." Do not confuse this use of authentication with other forms of authentication used with Vertica. For example, TLS/SSL's authentication of a client connection has nothing to do with Vertica user authentication. Even if you successfully establish a TLS/SSL connection to Vertica using a client, Vertica still requires you to provide a user name and password before you can interact with it.

## Configuring your scheduler for TLS connections

The scheduler can use TLS for two different connections: the one it makes to Vertica, and the connection it creates when running COPY statements to retrieve data from Kafka. Because the scheduler is a Java application, you supply the TLS key and the certificate used to sign it in a keystore. You also supply a truststore that contains in the certificates that the scheduler should trust. Both the connection to Vertica and to Kafka can use the same keystore and truststore. You can also choose to use separate keystores and truststores for these two connections by setting different JDBC settings for the scheduler. See [JDBC connection properties](#) for a list of these settings.

See [Kafka TLS-SSL Example Part 5: Configure the Scheduler](#) for detailed steps on configuring your scheduler to use SSL.

**Important**  
If you choose to use a file format other than the standard Java Keystore (JKS) format for your keystore or truststore files, you must use the correct file extension in the filename. For example, suppose you choose to use a keystore and truststore saved in PKCS#12 format. Then your keystore and truststore files must end with the `.pfx` or `.p12` extension.

If the scheduler does not recognize the file's extension (or there is no extension in the file name), it assumes that the file is in JKS format. If the file is not in JKS format, you will see an error message when starting the scheduler, similar to "Failed to create an SSLSocketFactory when setting up TLS: keystore not found."

Note that if the Kafka server's parameter `client.ssl.auth` is set to `none` or `requested`, you do not need to create a keystore.

## Using TLS/SSL when directly loading data from Kafka

You can manually load data from Kafka using the `COPY` statement and the `KafkaSource` user-defined load function (see [Manually consume data from Kafka](#)). To have `KafkaSource` open a secure connection to Kafka, you must supply it with an SSL key and other information.

When starting, the `KafkaSource` function checks if several user session variables are defined. These variables contain the SSL key, the certificate used to sign the key, and other information that the function needs to create the SSL connection. See [Kafka user-defined session parameters](#) for a list of these variables. If `KafkaSource` finds these variables are defined, it uses them to create an SSL connection to Kafka.

See [Kafka TLS/SSL Example Part 4: Loading Data Directly From Kafka](#) for a step-by-step guide on configuring and using an SSL connection when directly copying data from Kafka.

These variables are also used by the `KafkaExport` function to establish a secure connection to Kafka when exporting data.

## Configure Kafka for TLS/SSL

This page covers procedures for configuring TLS connections Vertica, Kafka, and the scheduler.

Note that the following example configures TLS for a Kafka server where `ssl.client.auth=required`, which requires the following:

- `kafka_SSL_Certificate`
- `kafka_SSL_PrivateKey_secret`
- `kafka_SSL_PrivateKeyPassword_secret`
- A keystore for the Scheduler

If your configuration uses `ssl.client.auth=none` or `ssl.client.auth=requested`, these parameters and the scheduler keystore are optional.

## Creating certificates for Vertica and clients

The CA certificate in this example is self-signed. In a production environment, you should instead use a trusted CA.

This example uses the same self-signed root CA to sign all of the certificates used by the scheduler, Kafka brokers, and Vertica. If you cannot use the same CA to sign the keys for all of these systems, make sure you include the entire chain of trust in your keystores.

For more information, see [Generating TLS certificates and keys](#).

1. Generate a private key, `root.key` .

```
$ openssl genrsa -out root.key
Generating RSA private key, 2048 bit long modulus
.....
.....+++
.....+++
e is 65537 (0x10001)
```

2. Generate a self-signed CA certificate.

```
$ openssl req -new -x509 -key root.key -out root.crt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.

Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com
```

3. Restrict to the owner read/write permissions for `root.key` and `root.crt` . Grant read permissions to other groups for `root.crt` .

```
$ ls
root.crt root.key
$ chmod 600 root.key
$ chmod 644 root.crt
```

4. Generate the server private key, `server.key` .

```
$ openssl genrsa -out server.key
Generating RSA private key, 2048 bit long modulus
.....+++
.....+++
e is 65537 (0x10001)
```

5. Create a certificate signing request (CSR) for your CA. Be sure to set the "Common Name" field to a wildcard (asterisk) so the certificate is accepted for all Vertica nodes in the cluster:

```
$ openssl req -new -key server.key -out server_reqout.txt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.

Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []: server_key_password
An optional company name []:
```

6. Sign the server certificate with your CA. This creates the server certificate `server.crt` .

```
$ openssl x509 -req -in server_reqout.txt -days 3650 -sha1 -CAcreateserial -CA root.crt \
-CAkey root.key -out server.crt
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=My Company/CN=*.mycompany.com/emailAddress=myemail@mycompany.com
Getting CA Private Key
```

7. Set the appropriate permissions for the key and certificate.

```
$ chmod 600 server.key
$ chmod 644 server.crt
```

Create a client key and certificate (mutual mode only)

In **Mutual Mode** , clients and servers verify each other's certificates before establishing a connection. The following procedure creates a client key and certificate to present to Vertica. The certificate must be signed by a CA that Vertica trusts.

The steps for this are identical to those above for creating a server key and certificate for Vertica.

```
$ openssl genrsa -out client.key
Generating RSA private key, 2048 bit long modulus
.....+++
.....+++
e is 65537 (0x10001)

$ openssl req -new -key client.key -out client_reqout.txt
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.

Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
Organizational Unit Name (eg, section) []:
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myemail@mycompany.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []: server_key_password
An optional company name []:

$ openssl x509 -req -in client_reqout.txt -days 3650 -sha1 -CAcreateserial -CA root.crt \
-CAkey root.key -out client.crt
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=My Company/CN=*.mycompany.com/emailAddress=myemail@mycompany.com
Getting CA Private Key

$ chmod 600 client.key
$ chmod 644 client.crt
```

Set up mutual mode client-server TLS

Configure Vertica for mutual mode

The following keys and certificates must be imported and then distributed to the nodes on your Vertica cluster with TLS Configuration for **Mutual Mode** :

- `root.key`
- `root.crt`
- `server.key`
- `server.crt`

You can view existing keys and certificates by querying [CRYPTOGRAPHIC\\_KEYS](#) and [CERTIFICATES](#).

1. Import the server and root keys and certificates into Vertica with [CREATE KEY](#) and [CREATE CERTIFICATE](#). See [Generating TLS certificates and keys](#) for details.

```
=> CREATE KEY imported_key TYPE 'RSA' AS '-----BEGIN PRIVATE KEY-----.....END PRIVATE KEY-----';
=> CREATE CA CERTIFICATE imported_ca AS '-----BEGIN CERTIFICATE-----.....END CERTIFICATE-----';
=> CREATE CERTIFICATE imported_cert AS '-----BEGIN CERTIFICATE-----.....END CERTIFICATE-----';
```

In this example, `\set` is used to retrieve the contents of `root.key`, `root.crt`, `server.key`, and `server.crt`.

```
=> \set ca_cert ""`cat root.crt`""
=> \set serv_key ""`cat server.key`""
=> \set serv_cert ""`cat server.crt`""

=> CREATE CA CERTIFICATE root_ca AS :ca_cert;
CREATE CERTIFICATE
=> CREATE KEY server_key TYPE 'RSA' AS :serv_key;
CREATE KEY
=> CREATE CERTIFICATE server_cert AS :serv_cert;
CREATE CERTIFICATE
```

2. Follow the steps for **Mutual Mode** in [Configuring client-server TLS](#) to set the proper TLSMODE and TLS Configuration parameters.

Configure a client for mutual mode

Clients must have their private key, certificate, and CA certificate. The certificate will be presented to Vertica when establishing a connection, and the CA certificate will be used to verify the server certificate from Vertica.

This example configures the `vsq` client for mutual mode.

1. Create a `.vsq` directory in the user's home directory.

```
$ mkdir ~/.vsq
```

2. Copy `client.key`, `client.crt`, and `root.crt` to the `vsq` directory.

```
$ cp client.key client.crt root.crt ~/.vsq
```

3. Log into Vertica with `vsq` and query the [SESSIONS](#) system table to verify that the connection is using mutual mode:

```
$ vsq
Password: user-password
Welcome to vsq, the Vertica Analytic Database interactive terminal.

Type: \h or \? for help with vsq commands
 \g or terminate with semicolon to execute query
 \q to quit

SSL connection (cipher: DHE-RSA-AES256-GCM-SHA384, bits: 256, protocol: TLSv1.2)

=> select user_name,ssl_state from sessions;
 user_name | ssl_state
-----+-----
 dbadmin | Mutual
(1 row)
```

Configure Kafka for TLS

Configure the Kafka brokers

This procedure configures Kafka to use TLS with client connections. You can also configure Kafka to use TLS to communicate between brokers. However, inter-broker TLS has no impact on establishing an encrypted connection between Vertica and Kafka.

1. Create a truststore file for all of your Kafka brokers, importing your CA certificate. This example uses the self-signed `root.crt` created above.

```

=> $ keytool -keystore kafka.truststore.jks -alias CARoot -import \
 -file root.crt
Enter keystore password: some_password
Re-enter new password: some_password
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US
Issuer: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US
Serial number: c3f02e87707d01aa
Valid from: Fri Mar 22 13:37:37 EDT 2019 until: Sun Apr 21 13:37:37 EDT 2019

]
]

Trust this certificate? [no]: yes
Certificate was added to keystore

```

2. Create a keystore file for the Kafka broker named `kafka01` . Each broker's keystore should be unique. The `keytool` command adds the a Subject Alternative Name (SAN) used as a fallback when establishing a TLS connection. Use your Kafka' broker's fully-qualified domain name (FQDN) as the value for the SAN and "What is your first and last name?" prompt. In this example, the FQDN is `kafka01.example.com` . The alias for `keytool` is set to `localhost` , so local connections to the broker use TLS.

```
$ keytool -keystore kafka01.keystore.jks -alias localhost -validity 365 -genkey -keyalg RSA \
-ext SAN=DNS:kafka01.mycompany.com
Enter keystore password: some_password
Re-enter new password: some_password
What is your first and last name?
[Unknown]: kafka01.mycompany.com
What is the name of your organizational unit?
[Unknown]:
What is the name of your organization?
[Unknown]: MyCompany
What is the name of your City or Locality?
[Unknown]: Cambridge
What is the name of your State or Province?
[Unknown]: MA
What is the two-letter country code for this unit?
[Unknown]: US
Is CN=Database Admin, OU=MyCompany, O=Unknown, L=Cambridge, ST=MA, C=US correct?
[no]: yes

Enter key password for <localhost>
(RETURN if same as keystore password):
```

3. Export the Kafka broker's certificate. In this example, the certificate is exported as **kafka01.unsigned.crt** .

```
$ keytool -keystore kafka01.keystore.jks -alias localhost \
-certreq -file kafka01.unsigned.crt
Enter keystore password: some_password
```

4. Sign the broker's certificate with the CA certificate.

```
$ openssl x509 -req -CA root.crt -CAkey root.key -in kafka01.unsigned.crt \
-out kafka01.signed.crt -days 365 -CAcreateserial
Signature ok
subject=/C=US/ST=MA/L=Cambridge/O=Unknown/OU=MyCompany/CN=Database Admin
Getting CA Private Key
```

5. Import the CA certificate into the broker's keystore.

#### Note

If you use different CAs to sign the certificates in your environment, you must add the entire chain of CAs you used to sign your certificate to the keystore, all the way up to the root CA. Including the entire chain of trust helps other systems verify the identity of your Kafka broker.

```
$ keytool -keystore kafka01.keystore.jks -alias CARoot -import -file root.crt
```

```
Enter keystore password: some_password
```

```

Trust this certificate? [no]: yes
```

```
Certificate was added to keystore
```

- If you are not logged into the Kafka broker for which you prepared the keystore, copy the truststore and keystore to it using `scp`. If you have already decided where to store the keystore and truststore files in the broker's filesystem, you can directly copy them to their final destination. This example just copies them to the root user's home directory temporarily. The next step moves them into their final location.

```
$ scp kafka.truststore.jks kafka01.keystore.jks root@kafka01.mycompany.com:
```

```
root@kafka01.mycompany.com's password: root_password
kafka.truststore.jks 100% 1048 1.0KB/s 00:00
kafka01.keystore.jks 100% 3277 3.2KB/s 00:00
```

- Repeat steps 2 through 7 for the remaining Kafka brokers.

Allow Kafka to read the keystore and truststore

If you did not copy the truststore and keystore to directory where Kafka can read them in the previous step, you must copy them to a final location on the broker. You must also allow the user account you use to run Kafka to read these files. The easiest way to ensure the user's access is to give this user ownership of these files.

In this example, Kafka is run by a Linux user `kafka`. If you use another user to run Kafka, be sure to set the permissions on the truststore and keystore files appropriately.

- Log into the Kafka broker as root.
- Copy the truststore and keystore to a directory where Kafka can access them. There is no set location for these files: you can choose a directory under `/etc`, or some other location where configuration files are usually stored. This example copies them from root's home directory to Kafka's configuration directory named `/opt/kafka/config/`. In your own system, this configuration directory may be in a different location depending on how you installed Kafka.
- Copy the truststore and keystore to a directory where Kafka can access them. There is no set location for these files: you can choose a directory under `/etc`, or some other location where configuration files are usually stored. This example copies them from root's home directory to Kafka's configuration directory named `/opt/kafka/config/`. In your own system, this configuration directory may be in a different location depending on how you installed Kafka.

```
~# cd /opt/kafka/config/
/opt/kafka/config# cp /root/kafka01.keystore.jks /root/kafka.truststore.jks .
```

- If you aren't logged in as a user account that runs Kafka, change the ownership of the truststore and keystore files. This example changes the ownership from root (which is the user currently logged in) to the kafka user:

```
/opt/kafka/config# ls -l
total 80
...
-rw-r--r-- 1 kafka nogroup 1221 Feb 21 2018 consumer.properties
-rw----- 1 root root 3277 Mar 27 08:03 kafka01.keystore.jks
-rw-r--r-- 1 root root 1048 Mar 27 08:03 kafka.truststore.jks
-rw-r--r-- 1 kafka nogroup 4727 Feb 21 2018 log4j.properties
...
/opt/kafka/config# chown kafka kafka01.keystore.jks kafka.truststore.jks
/opt/kafka/config# ls -l
total 80
...
-rw-r--r-- 1 kafka nogroup 1221 Feb 21 2018 consumer.properties
-rw----- 1 kafka root 3277 Mar 27 08:03 kafka01.keystore.jks
-rw-r--r-- 1 kafka root 1048 Mar 27 08:03 kafka.truststore.jks
-rw-r--r-- 1 kafka nogroup 4727 Feb 21 2018 log4j.properties
...
```

- Repeat steps 1 through 3 for the remaining Kafka brokers.

Configure Kafka to use TLS

With the truststore and keystore in place, your next step is to edit the Kafka's `server.properties` configuration file to tell Kafka to use TLS/SSL encryption. This file is usually stored in the Kafka config directory. The location of this directory depends on how you installed Kafka. In this example, the file is located in `/opt/kafka/config`.

When editing the files, be sure you do not change their ownership. The best way to ensure Linux does not change the file's ownership is to use `su` to become the user account that runs Kafka, assuming you are not already logged in as that user:

```
$/opt/kafka/config# su -s /bin/bash kafka
```

## Note

The previous command lets you start a shell as the kafka system user even if that user cannot log in.

The `server.properties` file contains Kafka broker settings in a `property = value` format. To configure the Kafka broker to use SSL, alter or add the following property settings:

### listeners

Host names and ports on which the Kafka broker listens. If you are not using SSL for connections between brokers, you must supply both a PLAINTEXT and SSL option. For example:

```
listeners=PLAINTEXT:// hostname :9092,SSL:// hostname :9093
```

### ssl.keystore.location

Absolute path to the keystore file.

### ssl.keystore.password

Password for the keystore file.

### ssl.key.password

Password for the Kafka broker's key in the keystore. You can make this password different than the keystore password if you choose.

### ssl.truststore.location

Location of the truststore file.

### ssl.truststore.password

Password to access the truststore.

### ssl.enabled.protocols

TLS/SSL protocols that Kafka allows clients to use.

### ssl.client.auth

Specifies whether SSL authentication is required or optional. The most secure setting for this setting is required to verify the client's identity.

Important  
These settings vary depending on your version of Kafka. Always consult the [Apache Kafka documentation](#) for your version of Kafka before making changes to `server.properties`. In particular, be aware that Kafka version 2.0 and later enables host name verification for clients and inter-broker communications by default.

This example configures Kafka to verify client identities via SSL authentication. It does not use SSL to communicate with other brokers, so the `server.properties` file defines both SSL and PLAINTEXT listener ports. It does not supply a host name for listener ports which tells Kafka to listen on the default network interface.

The lines added to the kafka01 broker's copy of `server.properties` for this configuration are:

```
listeners=PLAINTEXT://:9092,SSL://:9093
ssl.keystore.location=/opt/kafka/config/kafka01.keystore.jks
ssl.keystore.password=vertica
ssl.key.password=vertica
ssl.truststore.location=/opt/kafka/config/kafka.truststore.jks
ssl.truststore.password=vertica
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
ssl.client.auth=required
```

You must make these changes to the `server.properties` file on all of your brokers.

After making your changes to your broker's `server.properties` files, restart Kafka. How you restart Kafka depends on your installation:

- If Kafka is running as part of a Hadoop cluster, you can usually restart it from within whatever interface you use to control Hadoop (such as Ambari).
- If you installed Kafka directly, you can restart it either by directly running the `kafka-server-stop.sh` and `kafka-server-start.sh` scripts or via the Linux system's service control commands (such as `systemctl`). You must run this command on each broker.

Test the configuration

If you have not configured client authentication, you can quickly test whether Kafka can access its keystore by running the command:

```
$ openssl s_client -debug -connect broker_host_name:9093 -tls1
```

If Kafka is able to access its keystore, this command will output a dump of the broker's certificate (exit with CTRL+C):

```
=> # openssl s_client -debug -connect kafka01.mycompany.com:9093 -tls1
CONNECTED(00000003)
write to 0xa4e4f0 [0xa58023] (197 bytes => 197 (0xC5))

read from 0xa4e4f0 [0xa53ad3] (5 bytes => 5 (0x5))
0000 - 16 03 01 08 fc
...
```

The above method is not conclusive, however; it only tells you if Kafka is able to find its keystore.

The best test of whether Kafka is able to accept TLS connections is to configure the command-line Kafka producer and consumer. In order to configure these tools, you must first create a client keystore. These steps are identical to creating a broker keystore.

#### Note

This example assumes that Kafka has a topic named test that you can send test messages to.

1. Create the client keystore:

```
keytool -keystore client.keystore.jks -alias localhost -validity 365 -genkey -keyalg RSA -ext SAN=DNS:fqdn_of_client_system
```

2. Respond to the "What is your first and last name?" with the FQDN of the system you will use to run the producer and/or consumer. Answer the rest of the prompts with the details of your organization.
3. Export the client certificate so it can be signed:

```
keytool -keystore client.keystore.jks -alias localhost -certreq -file client.unsigned.cert
```

4. Sign the client certificate with the root CA:

```
openssl x509 -req -CA root.crt -CAkey root.key -in client.unsigned.cert -out client.signed.cert \
-days 365 -CAcreateserial
```

5. Add the root CA to keystore:

```
keytool -keystore client.keystore.jks -alias CARoot -import -file root.crt
```

6. Add the signed client certificate to the keystore:

```
keytool -keystore client.keystore.jks -alias localhost -import -file client.signed.cert
```

7. Copy the keystore to a location where you will use it. For example, you could choose to copy it to the same directory where you copied the keystore for the Kafka broker. If you choose to copy it to some other location, or intend to use some other user to run the command-line clients, be sure to add a copy of the truststore file you created for the brokers. Clients can reuse this truststore file for authenticating the Kafka brokers because the same CA is used to sign all of the certificates. Also set the file's ownership and permissions accordingly.

Next, you must create a properties file (similar to the broker's `server.properties` file) that configures the command-line clients to use TLS. For a client running on the Kafka broker named kafka01, your configuration file could look like this:

```
security.protocol=SSL
ssl.truststore.location=/opt/kafka/config/kafka.truststore.jks
ssl.truststore.password=trustore_password
ssl.keystore.location=/opt/kafka/config/client.keystore.jks
ssl.keystore.password=keystore_password
ssl.key.password=key_password
ssl.enabled.protocols=TLSv1.2,TLSv1.1,TLSv1
ssl.client.auth=required
```

This property file assumes the keystore file is located in the Kafka configuration directory.

Finally, you can run the command line producer or consumer to ensure they can connect and process data. You supply these clients the properties file you just created. The following example assumes you stored the properties file in the Kafka configuration directory, and that Kafka is installed in `/opt/kafka` :

```
~# cd /opt/kafka

/opt/kafka# bin/kafka-console-producer.sh --broker-list kafka01.mycompany.com:9093 \
--topic test --producer.config config/client.properties
>test
>test again
>More testing. These messages seem to be getting through!
^D
/opt/kafka# bin/kafka-console-consumer.sh --bootstrap-server kafaka01.mycompany.com:9093 --topic test \
--consumer.config config/client.properties --from-beginning
test
test again
More testing. These messages seem to be getting through!
^C
Processed a total of 3 messages
```

### Loading data from Kafka

After you configure Kafka to accept TLS connections, verify that you can directly load data from it into Vertica. You should perform this step even if you plan to create a scheduler to automatically stream data.

You can choose to create a separate key and certificate for directly loading data from Kafka. This example re-uses the key and certificate created for the Vertica server in part 2 of this example.

You directly load data from Kafka by using the [KafkaSource](#) data source function with the `COPY` statement (see [Manually consume data from Kafka](#)). The `KafkaSource` function creates the connection to Kafka, so it needs a key, certificate, and related passwords to create an encrypted connection. You pass this information via session parameters. See [Kafka user-defined session parameters](#) for a list of these parameters.

The easiest way to get the key and certificate into the parameters is by first reading them into [vsq variables](#). You get their contents by using back quotes to read the file contents via the Linux shell. Then you set the session parameters from the variables. Before setting the session parameters, increase the `MaxSessionUDParameterSize` session parameter to add enough storage space in the session variables for the key and the certificates. They can be larger than the default size limit for session variables (1000 bytes).

The following example reads the server key and certificate and the root CA from the a directory named `/home/dbadmin/SSL` . Because the server's key password is not saved in a file, the example sets it in a Linux environment variable named `KVERTICA_PASS` before running `vsq`. The example sets `MaxSessionUDParameterSize` to 100000 before setting the session variables. Finally, it enables TLS for the Kafka connection and streams data from the topic named `test`.

```

$ export KVERTICA_PASS=server_key_password
$ vsql
Password:
Welcome to vsql, the Vertica Analytic Database interactive terminal.

Type: \h or \? for help with vsql commands
 \g or terminate with semicolon to execute query

```

### Configure the scheduler

The final piece of the configuration is to set up the scheduler to use SSL when communicating with Kafka (and optionally with Vertica). When the scheduler runs a COPY command to get data from Kafka, it uses its own key and certificate to authenticate with Kafka. If you choose to have the scheduler use TLS/SSL to connect to Vertica, it can reuse the same keystore and truststore to make this connection.

### Create a truststore and keystore for the scheduler

Because the scheduler is a separate component, it must have its own key and certificate. The scheduler runs in Java and uses the JDBC interface to connect to Vertica. Therefore, you must create a keystore (when `ssl.client.auth=required`) and truststore for it to use when making a TLS-encrypted connection to Vertica.

Keep in mind that creating a keystore is optional if your Kafka server sets `ssl.client.auth` to `none` or `requested`.

This process is similar to creating the truststores and keystores for Kafka brokers. The main difference is using the the `-dname` option for `keytool` to set the Common Name (CN) for the key to a domain wildcard. Using this setting allows the key and certificate to match any host in the network. This option is especially useful if you run multiple schedulers on different servers to provide redundancy. The schedulers can use the same key and certificate, no matter which server they are running on in your domain.

1. Create a truststore file for the scheduler. Add the CA certificate that you used to sign the keystore of the Kafka cluster and Vertica cluster. If you are using more than one CA to sign your certificates, add all of the CAs you used.

```
$ keytool -keystore scheduler.truststore.jks -alias CARoot -import \
-file root.crt
Enter keystore password: some_password
Re-enter new password: some_password
Owner: EMAILADDRESS=myemail@mycompany.com, CN=*.mycompany.com, O=MyCompany, L=Cambridge, ST=MA, C=US

0010: E5 3D 78 16 .=x.
]
]

Trust this certificate? [no]: yes
Certificate was added to keystore
```

2. Initialize the keystore, passing it a wildcard host name as the Common Name. The alias parameter in this command is important, as you use it later to identify the key the scheduler must use when creating SSL connections:

```
keytool -keystore scheduler.keystore.jks -alias vsched -validity 365 -genkey \
-keyalg RSA -dname CN=*.mycompany.com
```

#### Important

If you choose to use a file format other than the standard Java Keystore (JKS) format for your keystore or truststore files, you must use the correct file extension in the filename. For example, suppose you choose to use a keystore and truststore saved in PKCS#12 format. Then your keystore and truststore files must end with the `.pfx` or `.p12` extension.

If the scheduler does not recognize the file's extension (or there is no extension in the file name), it assumes that the file is in JKS format. If the file is not in JKS format, you will see an error message when starting the scheduler, similar to "Failed to create an SSLSocketFactory when setting up TLS: keystore not found."

3. Export the scheduler's key so you can sign it with the root CA:

```
$ keytool -keystore scheduler.keystore.jks -alias vsched -certreq \
-file scheduler.unsigned.cert
```

4. Sign the scheduler key with the root CA:

```
$ openssl x509 -req -CA root.crt -CAkey root.key -in scheduler.unsigned.cert \
-out scheduler.signed.cert -days 365 -CAcreateserial
```

5. Re-import the scheduler key into the keystore:

```
$ keytool -keystore scheduler.keystore.jks -alias localhost -import -file scheduler.signed.cert
```

Set environment variable VKCONFIG\_JVM\_OPTS

You must pass several settings to the JDBC interface of the Java Virtual Machine (JVM) that runs the scheduler. These settings tell the JDBC driver where to find the keystore and truststore, as well as the key's password. The easiest way to pass in these settings is to set a Linux environment variable named VKCONFIG\_JVM\_OPTS. As it starts, the scheduler checks this environment variable and passes any properties defined in it to the JVM.

The properties that you need to set are:

- `javax.net.ssl.keystore`: the absolute path to the keystore file to use.
- `javax.net.ssl.keyStorePassword`: the password for the scheduler's key.
- `javax.net.ssl.trustStore`: The absolute path to the truststore file.

The Linux command line to set the environment variable is:

```
export VKCONFIG_JVM_OPTS="$VKCONFIG_JVM_OPTS -Djavax.net.ssl.trustStore=/path/to/truststore \
-Djavax.net.ssl.keyStore=/path/to/keystore \
-Djavax.net.ssl.keyStorePassword=keystore_password"
```

#### Note

The previous command preserves any existing contents of the VKCONFIG\_JVM\_OPTS variable. If you find the variable has duplicate settings, remove the `$VKCONFIG_JVM_OPTS` from your statement so you override the existing values in the variable.

For example, suppose the scheduler's truststore and keystore are located in the directory `/home/dbadmin/SSL`. Then you could use the following command to set the VKCONFIG\_JVM\_OPTS variable:

```
$ export VKCONFIG_JVM_OPTS="$VKCONFIG_JVM_OPTS \
-Djavax.net.ssl.trustStore=/home/dbadmin/SSL/scheduler.truststore.jks \
-Djavax.net.ssl.keyStore=/home/dbadmin/SSL/scheduler.keystore.jks \
-Djavax.net.ssl.keyStorePassword=key_password"
```

#### Important

The Java property names are case sensitive.

To ensure that this variable is always set, add the command to the `~/.bashrc` or other startup file of the user account that runs the scheduler.

If you require TLS on the JDBC connection to Vertica, add `TLSmode=require` to the JDBC URL that the scheduler uses. The easiest way to add this is to use the scheduler's `--jdbc-url` option. Assuming that you use a configuration file for your scheduler, you can add this line to it:

```
--jdbc-url=jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password&TLSmode=require
```

For more information about using the JDBC with Vertica, see [Java](#).

Enable TLS in the scheduler configuration

Lastly, enable TLS. Every time you run `vkconfig`, you must pass it the following options:

#### --enable-ssl

`true`, to enable the scheduler to use SSL when connecting to Kafka.

### --ssl-ca-alias

Alias for the CA you used to sign your Kafka broker's keys. This must match the value you supplied to the `-alias` argument of the `keytool` command to import the CA into the truststore.

#### Note

If you used more than one CA to sign keys, omit this option to import all of the CAs into the truststore.

### --ssl-key-alias

Alias assigned to the scheduler key. This value must match the value you supplied to the `-alias` you supplied to the `keytool` command when creating the scheduler's keystore.

### --ssl-key-password

Password for the scheduler key.

See [Common vkconfig script options](#) for details of these options. For convenience and security, add these options to a configuration file that you pass to `vkconfig`. Otherwise, you run the risk of exposing the key password via the process list which can be viewed by other users on the same system. See [Configuration File Format](#) for more information on setting up a configuration file.

Add the following to the scheduler configuration file to allow it to use the keystore and truststore and enable TLS when connecting to Vertica:

```
enable-ssl=true
ssl-ca-alias=CAroot
ssl-key-alias=vsched
ssl-key-password=vertica
jdbc-url=jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password&TLSmode=require
```

Start the scheduler

Once you have configured the scheduler to use SSL, start it and verify that it can load data. For example, to start the scheduler with a configuration file named `weblog.conf`, use the command:

```
$ nohup vkconfig launch --conf weblog.conf >/dev/null 2>&1 &
```

## Troubleshooting Kafka TLS/SSL connection issues

After configuring Vertica, Kafka, and your scheduler to use TLS/SSL authentication and encryption, you may encounter issues with data streaming. This section explains some of the more common errors you may encounter, and how to trouble shoot them.

### Errors when launching the scheduler

You may see errors like this when launching the scheduler:

```
$ vkconfig launch --conf weblog.conf
java.sql.SQLException: com.vertica.solutions.kafka.exception.ConfigurationException:
 No keystore system property found: null
 at com.vertica.solutions.kafka.util.SQLUtilities.getConnection(SQLUtilities.java:181)
 at com.vertica.solutions.kafka.cli.CLIUtil.assertDBCConnectionWorks(CLIUtil.java:40)
 at com.vertica.solutions.kafka.Launcher.run(Launcher.java:135)
 at com.vertica.solutions.kafka.Launcher.main(Launcher.java:263)
Caused by: com.vertica.solutions.kafka.exception.ConfigurationException: No keystore system property found: null
 at com.vertica.solutions.kafka.security.KeyStoreUtil.loadStore(KeyStoreUtil.java:77)
 at com.vertica.solutions.kafka.security.KeyStoreUtil.<init>(KeyStoreUtil.java:42)
 at com.vertica.solutions.kafka.util.SQLUtilities.getConnection(SQLUtilities.java:179)
 ... 3 more
```

The scheduler throws these errors when it cannot locate or read the keystore or truststore files. To resolve this issue:

- Verify you have set the `VKCONFIG_JVM_OPTS` Linux environment variable. Without this variable, the scheduler will not know where to find the truststore and keystore to use when creating TLS/SSL connections. See [Step 2: Set the VKCONFIG\\_JVM\\_OPTS Environment Variable](#) for more information.
- Verify that the keystore and truststore files are located in the path you set in the `VKCONFIG_JVM_OPTS` environment variable.
- Verify that the user account that runs the scheduler has read access to the truststore and keystore files.
- Verify that the key password you provide in the scheduler configuration is correct. Note that you must supply the password for the key, not the keystore.

Another possible error message is a failure to set up a TLS Keystore:

```
Exception in thread "main" java.sql.SQLRecoverableException: [Vertica][VJDBC](100024) IOException while communicating with server: java.io.IOException:
Failed to create an SSLSocketFactory when setting up TLS: keystore not found.
 at com.vertica.io.ProtocolStream.logAndConvertToNetworkException(Unknown Source)
 at com.vertica.io.ProtocolStream.enableSSL(Unknown Source)
 at com.vertica.io.ProtocolStream.initSession(Unknown Source)
 at com.vertica.core.VConnection.tryConnect(Unknown Source)
 at com.vertica.core.VConnection.connect(Unknown Source)
 . . .
```

This error can be caused by using a keystore or truststore file in a format other than JKS and not supplying the correct file extension. If the scheduler does not recognize the file extension of your keystore or truststore file name, it assumes the file is in JKS format. If the file isn't in this format, the scheduler will exit with the error message shown above. To correct this error, rename the keystore and truststore files to use the correct file extension. For example, if your files are in PKCS 12 filemat, change their file extension to `.p12` or `.pks`.

Data does not load

If you find that scheduler is not loading data into your database, you should first query the [stream\\_microbatch\\_history](#) table to determine whether the scheduler is executing microbatches, and if so, what their results are. A faulty TLS/SSL configuration usually results in a status of NETWORK\_ISSUE:

```
=> SELECT frame_start, end_reason, end_reason_message FROM weblog_sched.stream_microbatch_history;
 frame_start | end_reason | end_reason_message
-----+-----+-----
2019-04-05 11:35:18.365 | NETWORK_ISSUE |
2019-04-05 11:35:38.462 | NETWORK_ISSUE |
```

If you suspect an SSL issue, you can verify that Vertica is establishing a connection to Kafka by looking at Kafka's `server.log` file. Failed SSL connection attempts can appear in this log like this example:

```
java.io.IOException: Unexpected status returned by SSLEngine.wrap, expected
CLOSED, received OK. Will not send close message to peer.
 at org.apache.kafka.common.network.SslTransportLayer.close(SslTransportLayer.java:172)
 at org.apache.kafka.common.utils.Utils.closeAll(Utils.java:703)
 at org.apache.kafka.common.network.KafkaChannel.close(KafkaChannel.java:61)
 at org.apache.kafka.common.network.Selector.doClose(Selector.java:739)
 at org.apache.kafka.common.network.Selector.close(Selector.java:727)
 at org.apache.kafka.common.network.Selector.pollSelectionKeys(Selector.java:520)
 at org.apache.kafka.common.network.Selector.poll(Selector.java:412)
 at kafka.network.Processor.poll(SocketServer.scala:551)
 at kafka.network.Processor.run(SocketServer.scala:468)
 at java.lang.Thread.run(Thread.java:748)
```

If you do not see errors of this sort, you likely have a network problem between Kafka and Vertica. If you do see these errors, consider the following debugging steps:

- Verify that the configuration of your Kafka cluster is uniform. For example, you may see connection errors if some Kafka nodes are set to require client authentication and others aren't.
- Verify that the Common Names (CN) in the certificates and keys match the host name of the system.
- Verify that the Kafka cluster is accepting connections on the ports and host names you specify in the `server.properties` file's listeners property. For example, suppose you use IP addresses in this setting, but use host names when defining the cluster in the scheduler's configuration. Then Kafka may reject the connection attempt by Vertica or Vertica may reject the Kafka node's identity.
- If you are using client authentication in Kafka, try turning it off to see if the scheduler can connect. If disabling authentication allows the scheduler to stream data, then you can isolate the problem to client authentication. In this case, review the certificates and CAs of both the Kafka cluster and the scheduler. Ensure that the truststores include all of the CAs used to sign the key, up to and including the root CA.

Avro schema registry and KafkaAvroParser

At minimum, the [KafkaAvroParser](#) requires the following parameters to create a TLS connection between the Avro Schema Registry and Vertica:

- `schema_registry_url` with the https scheme
- `schema_registry_ssl_ca_path`

If and only if TLS access fails, determine what TLS schema registry information Vertica requires from the following:

- Certificate Authority (CA)

- TLS server certificate
- TLS key

Provide only the necessary TLS schema registry information with KafkaAvroParser parameters. The TLS information must be accessible in the filesystem of each Vertica node that processes Avro data.

The following example shows how to pass these parameters to KafkaAvroParser:

```
KafkaAvroParser(
 schema_registry_url='https://localhost:8081'
 schema_registry_ssl_ca_path='path/to/certificate-authority',
 schema_registry_ssl_cert_path='path/to/tls-server-certificate',
 schema_registry_ssl_key_path='path/to/private-tls-key',
 schema_registry_ssl_key_password_path='path/to/private-tls-key-password'
)
```

## Authenticating with Kafka using SASL

Kafka supports using Simple Authentication and Security Layer (SASL) to authenticate producers and consumers. You can use SASL to authenticate Vertica with Kafka when using most of the Kafka-related functions such as [KafkaSource](#).

Vertica supports using the SASL\_PLAINTEXT and SASL\_SSL protocols with the following authentication mechanisms:

- PLAIN
- SCRAM-SHA-256
- SCRAM-SHA-512

You must configure your Kafka cluster to enable SASL authentication. See the [Kafka documentation](#) for your Kafka version to learn how to configure SASL authentication.

### Note

[KafkaExport](#) does not support using TLS/SSL with SASL authentication at this time.

To use SASL authentication between Vertica and Kafka, directly set SASL-related configuration options in the rdkafka library using the `kafka_conf` parameter. Vertica uses this library to connect to Kafka. See [Directly setting Kafka library options](#) for more information on directly setting configuration options in the rdkafka library.

Among the relevant configuration options are:

- `security.protocol` sets the security protocol to use to authenticate with Kafka.
- `sasl.mechanism` sets the security mechanism.
- `sasl.username` sets the SASL user to use for authentication.
- `sasl.password` sets the password to use for SASL authentication.

See the [rdkafka configuration documentation](#) for a list of all the SASL-related settings.

The following example demonstrates calling [KafkaCheckBrokers](#) using the `SASL_PLAINTEXT` security protocol:

```
=> SELECT KafkaCheckBrokers(USING PARAMETERS
 brokers='kafka01.example.com:9092',
 kafka_conf='{"sasl.username":"dbadmin", "sasl.mechanism":"PLAIN", "security.protocol":"SASL_PLAINTEXT"}',
 kafka_conf_secret='{"sasl.password":"password"}'
) OVER ();
```

This example demonstrates using SASL authentication when copying data from Kafka via an SSL connection. This example assumes that Vertica and Kafka have been configured to use TLS/SSL encryption as described in [TLS/SSL encryption with Kafka](#):

```
=> COPY mytopic_table
SOURCE KafkaSource(
 stream='mytopic|0|-2',
 brokers='kafka01.example.com:9092',
 stop_on_eof=true,
 kafka_conf={'sasl.username':"dbadmin", "sasl.password":"pword", "sasl.mechanism":"PLAIN", "security.protocol":"SASL_SSL"}
)
FILTER KafkaInsertDelimiters(delimiter = E'\n')
DELIMITER ','
ENCLOSED BY '';
```

For more information about using SASL with the rdkafka library, see [Using SASL with librdkafka](#) on the rdkafka github site.

## Troubleshooting Kafka integration issues

The following topics can help you troubleshoot issues integrating Vertica with Apache Kafka.

In this section

- [Using kafkacat to troubleshoot Kafka integration issues](#)
- [Troubleshooting slow load speeds](#)
- [Troubleshooting missing messages](#)

### Using kafkacat to troubleshoot Kafka integration issues

Kafkacat is a third-party open-source utility that lets you connect to Kafka from the Linux command line. It uses the same underlying library that the Vertica integration for Apache Kafka uses to connect to Kafka. This shared library makes kafkacat a useful tool for testing and debugging your Vertica integration with Kafka.

You may find kafkacat useful for:

- Testing connectivity between your Vertica and Kafka clusters.
- Examining Kafka data for anomalies that may prevent some of it from loading into Vertica.
- Producing data for test loads into Vertica.
- Listing details about a Kafka topic.

For more information about kafkacat, see its [project page at Github](#).

### Running kafkacat on Vertica nodes

The kafkacat utility is bundled in the Vertica install package, so it is available on all nodes of your Vertica cluster in the `/opt/vertica/packages/kafka/bin` directory. This is the same directory containing the vkconfig utility, so if you have added it to your path, you can use the kafkacat utility without specifying its full path. Otherwise, you can add this path to your shell's environment variable using the command:

```
set PATH=/opt/vertica/packages/kafka/bin:$PATH
```

#### Note

On Debian and Ubuntu systems, you must tell kafkacat to use Vertica's own copy of the SSL libraries by setting the LD\_LIBRARY\_PATH environment variable:

```
$ export LD_LIBRARY_PATH=/opt/vertica/lib
```

If you do not set this environment variable, the kafkacat utility exits with the error:

```
kafkacat: error while loading shared libraries: libcrypto.so.10:
cannot open shared object file: No such file or directory
```

Executing kafkacat without any arguments gives you a basic help message:

```
$ kafkacat
Error: -b <broker,...> missing

Usage: kafkacat <options> [file1 file2 .. | topic1 topic2 ..]
kafkacat - Apache Kafka producer and consumer tool
```

<https://github.com/edenhill/kafkacat>

Copyright (c) 2014-2015, Magnus Edenhill

Version releases/VER\_8\_1\_RELEASE\_BUILD\_1\_555\_20170615-4931-g3fb918 (librdkafka releases/VER\_8\_1\_RELEASE\_BUILD\_1\_555\_20170615-4931-g3fb918)

#### General options:

- C | -P | -L Mode: Consume, Produce or metadata List
- G <group-id> Mode: High-level KafkaConsumer (Kafka 0.9 balanced consumer groups)  
Expects a list of topics to subscribe to
- t <topic> Topic to consume from, produce to, or list
- p <partition> Partition
- b <brokers,..> Bootstrap broker(s) (host[:port])
- D <delim> Message delimiter character:  
a-z.. | \r | \n | \t | \xNN  
Default: \n
- K <delim> Key delimiter (same format as -D)
- c <cnt> Limit message count
- X list List available librdkafka configuration properties
- X prop=val Set librdkafka configuration property.  
Properties prefixed with "topic." are applied as topic properties.
- X dump Dump configuration and exit.
- d <dbg1,..> Enable librdkafka debugging:  
all,generic,broker,topic,metadata,queue,msg,protocol,cgrp,security,fetch,feature
- q Be quiet (verbosity set to 0)
- v Increase verbosity
- V Print version

#### Producer options:

- z snappy|gzip Message compression. Default: none
- p -1 Use random partitioner
- D <delim> Delimiter to split input into messages
- K <delim> Delimiter to split input key and message
- l Send messages from a file separated by  
delimiter, as with stdin.  
(only one file allowed)
- T Output sent messages to stdout, acting like tee.
- c <cnt> Exit after producing this number of messages
- Z Send empty messages as NULL messages
- file1 file2.. Read messages from files.  
With -l, only one file permitted.  
Otherwise, the entire file contents will  
be sent as one single message.

#### Consumer options:

- o <offset> Offset to start consuming from:  
beginning | end | stored |  
<value> (absolute offset) |  
-<value> (relative offset from end)
- e Exit successfully when last message received
- f <fmt..> Output formatting string, see below.  
Takes precedence over -D and -K.
- D <delim> Delimiter to separate messages on output
- K <delim> Print message keys prefixing the message  
with specified delimiter.
- O Print message offset using -K delimiter
- c <cnt> Exit after consuming this number of messages
- Z Print NULL messages and keys as "NULL"(instead of empty)
- u Unbuffered output

#### Metadata options:

-t <topic> Topic to query (optional)

#### Format string tokens:

%s Message payload  
%S Message payload length (or -1 for NULL)  
%R Message payload length (or -1 for NULL) serialized  
as a binary big endian 32-bit signed integer  
%k Message key  
%K Message key length (or -1 for NULL)  
%t Topic  
%p Partition  
%o Message offset  
\n \r \t Newlines, tab  
\xXX \xNNN Any ASCII character

#### Example:

```
-f 'Topic %t [%p] at offset %o: key %k: %s\n'
```

#### Consumer mode (writes messages to stdout):

```
kafkacat -b <broker> -t <topic> -p <partition>
```

or:

```
kafkacat -C -b ...
```

#### High-level KafkaConsumer mode:

```
kafkacat -b <broker> -G <group-id> topic1 top2 ^aregex\d+
```

#### Producer mode (reads messages from stdin):

```
... | kafkacat -b <broker> -t <topic> -p <partition>
```

or:

```
kafkacat -P -b ...
```

#### Metadata listing:

```
kafkacat -L -b <broker> [-t <topic>]
```

#### Testing connectivity to a Kafka cluster and getting metadata

One basic troubleshooting step you often need to perform is verifying that Vertica nodes can connect to the Kafka cluster. Successfully executing just about any kafkacat command will prove the Vertica node you are logged into is able to reach the Kafka cluster. One simple command you can execute to verify connectivity is to get the metadata for all of the topics the Kafka cluster has defined. The following example demonstrates using kafkacat's metadata listing command to connect to the broker named kafka01 running on port 6667 (the Kafka broker port used by Hortonworks Hadoop clusters).

```
$ kafkacat -L -b kafka01:6667
```

Metadata for all topics (from broker -1: kafka01:6667/bootstrap):

2 brokers:

```
broker 1001 at kafka03.example.com:6667
```

```
broker 1002 at kafka01.example.com:6667
```

4 topics:

topic "iot-data" with 3 partitions:

```
partition 2, leader 1002, replicas: 1002, isrs: 1002
```

```
partition 1, leader 1001, replicas: 1001, isrs: 1001
```

```
partition 0, leader 1002, replicas: 1002, isrs: 1002
```

topic "\_\_consumer\_offsets" with 50 partitions:

```
partition 23, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 41, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 32, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 8, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 17, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 44, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 35, leader 1001, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 26, leader 1002, replicas: 1002,1001, isrs: 1001,1002
```

```
partition 11, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 29, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 38, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 47, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 20, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 2, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 5, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 14, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 46, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 49, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 40, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 4, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 13, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 22, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 31, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 16, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 7, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 43, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 25, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 34, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 10, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 37, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 1, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 19, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 28, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 45, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 36, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 27, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 9, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 18, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 21, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 48, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 12, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 3, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 30, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 39, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 15, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 42, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 24, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 33, leader 1001, replicas: 1002,1001, isrs: 1001,1002
partition 6, leader 1002, replicas: 1002,1001, isrs: 1001,1002
partition 0, leader 1002, replicas: 1002,1001, isrs: 1001,1002
topic "web_hits" with 1 partitions:
 partition 0, leader 1001, replicas: 1001, isrs: 1001
topic "ambari_kafka_service_check" with 1 partitions:
 partition 0, leader 1002, replicas: 1002, isrs: 1002
```

You can also use this output to verify the topics defined by your Kafka cluster, as well as the number of partitions each topic defines. You need this information when copying data between Kafka and Vertica.

#### Retrieving messages from a Kafka topic

When you are troubleshooting issues with streaming messages from Kafka in Vertica, you often want to look at the raw data that Kafka sent. For example, you may want to verify that the messages are in the format that you expect. Or, you may want to review specific messages to see if some of them weren't in the right format for Vertica to parse. You can use `kafkacat` to read messages from a topic using its consume command ( `-C` ). At the very least, you must pass `kafkacat` the brokers ( `-b` argument) and the topic you want to read from ( `-t` ). You can also choose to read messages from a specific offset ( `-o` ) and partition ( `-p` ). You will usually also want `kafkacat` to exit after completing the data read ( `-e` ) instead continuing to wait for more messages.

This example gets the last message in the topic named `web_hits`. The offset argument uses a negative value, which tells `kafkacat` to read from the end of the topic.

```
$ kafkacat -C -b kafka01:6667 -t web_hits -o -1 -e
{"url": "wp-content/list/search.php", "ip": "132.74.240.52",
"date": "2018/03/28 14:12:34",
"user_agent": "Mozilla/5.0 (iPod; U; CPU iPhone OS 4_2 like
Mac OS X; sl-SI) AppleWebKit/532.22.4 (KHTML, like Gecko) Version/3.0.5
Mobile/8B117 Safari/6532.22.4"}
% Reached end of topic web_hits [0] at offset 54932: exiting
```

You can also read a specific range of messages by specifying an offset and a limit ( `-c` argument). For example, you may want to look at a specific range of data to determine why Vertica could not load it. The following example reads 10 messages from the topic `iot-data` starting at offset 3280:

```
$ kafkacat -C -b kafka01:6667 -t iot-data -o 3280 -c 10 -e
63680, 19, 24.439323, 26.0128725
43510, 71, 162.319805, -37.4924025
91113, 53, 139.764857, -74.735731
88508, 14, -85.821967, -7.236280
20419, 31, -129.583988, 13.995481
79365, 79, 153.184594, 51.1583485
26283, 25, -168.911020, 35.331027
32111, 56, -157.930451, 82.2676385
56808, 17, 19.603286, -0.7698495
91118, 73, 97.365445, -74.8593245
```

### Generating data for a Kafka topic

If you are preparing to stream data from a Kafka topic that is not yet active, you may want a way to stream test messages. You can then verify that the topic's messages load into Vertica without worrying that you will miss actual data.

To send data to Kafka, use `kafkacat`'s `produce` command (`-P`). The easiest way to supply it with messages is to pipe them in via STDIN, one message per line. You can choose a specific partition for the data, or have `kafkacat` randomly assign each message to a random partition by setting the partition number to `-1`. For example, suppose you have a file named `iot-data.csv` that you wanted to produce to random partitions of a Kafka topic named `iot-data`. Then you could use the following command:

```
$ cat iot_data.csv | kafkacat -P -p -1 -b kafka01:6667 -t iot-data
```

### Troubleshooting slow load speeds

Here are some potential issues that could cause messages to load slowly from Kafka.

Verify you have disabled the API version check when communicating with Kafka 0.9 or earlier

If your Kafka cluster is running 0.9 or earlier, be sure you have disabled the `rdkafka` library's `api.version.request` option. If you do not, every Vertica connection to Kafka will pause for 10 seconds until the API version request times out. Depending on the frame size of your load or other timeout settings, this delay can either reduce the throughput of your data loads. It can even totally prevent messages from being loaded. See [Configuring Vertica for Apache Kafka version 0.9 and earlier](#) for more information.

### Eon Mode and cloud latency

Eon Mode separates compute from storage in a Vertica cluster, which can cause a small amount of latency when Vertica loads and saves data. Cloud computing infrastructure can also cause latency. This latency can eat into the frame duration for your schedulers, causing them to load less data in each frame. For this reason, you should consider increasing frame durations when loading data from Kafka in an Eon Mode database. See [Vertica Eon Mode and Kafka](#) for more information.

### Troubleshooting missing messages

Kafka producers that emit a high data volume might overwhelm Vertica, possibly resulting in messages expiring in Kafka before the [scheduler](#) loads them into Vertica. This is more common when Vertica performs additional processing on the loaded messages, such as text indexing.

If you see that you are missing messages from a topic with multiple partitions, consider configuring the `--max-parallelism` [microbatch utility option](#). The `--max-parallelism` option splits a microbatch into multiple subset microbatches. This enables you to use `PLANNEDCONCURRENCY` available in the scheduler's resource pool to create more scheduler threads for simultaneous loads of a single microbatch. Each node uses the resource pool `EXECUTIONPARALLELISM` setting to determine the number of threads created to process partitions. Because `EXECUTIONPARALLELISM` threads are created per scheduler thread, using more `PLANNEDCONCURRENCY` per microbatch enables you to process more partitions in parallel for a single unit of work.

For details, see [Managing scheduler resources and performance](#).

## vkconfig script options

Vertica includes the vkconfig script that lets you configure your schedulers. This script contains multiple tools that set groups of options in the scheduler, as well as starting and shutting it down. You supply the tool you want to use as the first argument in your call to the vkconfig script.

The topics in this section explain each of the tools available in the vkconfig script as well as their options. You can use the options in the [Common vkconfig script options](#) topic with any of the utilities. Utility-specific options appear in their respective tables.

In this section

- [Common vkconfig script options](#)
- [Scheduler tool options](#)
- [Cluster tool options](#)
- [Source tool options](#)
- [Target tool options](#)
- [Load spec tool options](#)
- [Microbatch tool options](#)
- [Launch tool options](#)
- [Shutdown tool options](#)
- [Statistics tool options](#)
- [Sync tool options](#)

### Common vkconfig script options

These options are available across the different tools available in the vkconfig script.

#### **--conf** *filename*

A text file containing configuration options for the vkconfig script. See [Configuration File Format](#) below.

#### **--config-schema** *schema\_name*

The name of the scheduler's Vertica schema. This value is the same as the name of the scheduler. You use this name to identify the scheduler during configuration.

**Default:**

stream\_config

#### **--dbhost** *host name*

The host name or IP address of the Vertica node acting as the initiator node for the scheduler.

**Default:**

localhost

#### **--dbport** *port\_number*

The port to use to connect to a Vertica database.

**Default:**

5433

#### **--enable-ssl**

Enables the vkconfig script to use SSL to connect to Vertica or between Vertica and Kafka. See [Configuring your scheduler for TLS connections](#) for more information.

#### **--help**

Prints out a help menu listing available options with a description.

#### **--jdbc-opt** *option = value* [& *option2 = value2* ...]

One or more options to add to the standard JDBC URL that vkconfig uses to connect to Vertica. Cannot be combined with `--jdbc-url`.

#### **--jdbc-url** *url*

A complete JDBC URL that vkconfig uses instead of standard JDBC URL string to connect to Vertica.

#### **--password** *password*

Password for the database user.

#### **--ssl-ca-alias** *alias\_name*

The alias of the root certificate authority in the truststore. When set, the scheduler loads only the certificate associated with the specified alias. When omitted, the scheduler loads all certificates into the truststore.

**--ssl-key-alias** *alias\_name*

The alias of the key and certificate pairs within the keystore. Must be set when Vertica uses SSL to connect to Kafka.

**--ssl-key-password** *password*

The password for the SSL key. Must be set when Vertica uses SSL to connect to Kafka.

**Caution**

Specifying this option on the command line can expose it to other users logged into the host. Always use a configuration file to set this option.

**--username** *username*

The Vertica database user used to alter the configuration of the scheduler. This user must have create privileges on the scheduler's schema.

**Default:**

Current user

**--version**

Displays the version number of the scheduler.

## Configuration file format

You can use a configuration file to store common parameters you use in your calls to the vkconfig utility. The configuration file is a text file containing one option setting per line in the format:

```
option=value
```

You can also include comments in the option file by prefixing them with a hash mark (#).

```
#config.properties:
username=myuser
password=mypassword
dbhost=localhost
dbport=5433
```

You tell vkconfig to use the configuration file using the --conf option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties
```

You can override any stored parameter from the command line:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --conf config.properties --dbhost otherVerticaHost
```

## Examples

These examples show how you can use the shared utility options.

Display help for the scheduler utility:

```
$ vkconfig scheduler --help
This command configures a Scheduler, which can run and load data from configured sources and clusters into Vertica tables. It provides options for changing the 'frame duration' (time given per set of batches to resolve), as well as the dedicated Vertica resource pool the Scheduler will use while running.
```

## Available Options:

PARAMETER	#ARGS	DESCRIPTION
conf	1	Allow the use of a properties file to associate parameter keys and values. This file enables command string reuse and cleaner command strings.
help	0	Outputs a help context for the given subutility.
version	0	Outputs the current Version of the scheduler.
skip-validation	0	[Deprecated] Use --validation-type.
validation-type	1	Determine what happens when there are configuration errors. Accepts: ERROR - errors out, WARN - prints out a message and continues, SKIP - skip running validations

ORC Snippet running validations

dbhost	1	The Vertica database hostname that contains metadata and configuration information. The default value is 'localhost'.
dbport	1	The port at the hostname to connect to the Vertica database. The default value is '5433'.
username	1	The user to connect to Vertica. The default value is the current system user.
password	1	The password for the user connecting to Vertica. The default value is empty.
jdbc-url	1	A JDBC URL that can override Vertica connection parameters and provide additional JDBC options.
jdbc-opt	1	Options to add to the JDBC URL used to connect to Vertica ('&'-separated key=value list). Used with generated URL (i.e. not with '--jdbc-url' set).
enable-ssl	1	Enable SSL between JDBC and Vertica and/or Vertica and Kafka.
ssl-ca-alias	1	The alias of the root CA within the provided truststore used when connecting between Vertica and Kafka.
ssl-key-alias	1	The alias of the key and certificate pair within the provided keystore used when connecting between Vertica and Kafka.
ssl-key-password	1	The password for the key used when connecting between Vertica and Kafka. Should be hidden with file access (see --conf).
config-schema	1	The schema containing the configuration details to be used, created or edited. This parameter defines the scheduler. The default value is 'stream_config'.
create	0	Create a new instance of the supplied type.
read	0	Read an instance of the supplied type.
update	0	Update an instance of the supplied type.
delete	0	Delete an instance of the supplied type.
drop	0	Drops the specified configuration schema. CAUTION: this command will completely delete and remove all configuration and monitoring data for the specified scheduler.
dump	0	Dump the config schema query string used to answer this command in the output.
operator	1	Specifies a user designated as an operator for the created configuration. Used with --create.
add-operator	1	Add a user designated as an operator for the specified configuration. Used with --update.
remove-operator	1	Removes a user designated as an operator for the specified configuration. Used with --update.
upgrade	0	Upgrade the current scheduler configuration schema to the current version of this scheduler. WARNING: if upgrading between EXCAVATOR and FRONTLOADER be aware that the Scheduler is not backwards compatible. The upgrade procedure will translate your kafka model into the new stream model.
upgrade-to-schema	1	Used with upgrade: will upgrade the configuration to a new given schema instead of upgrading within the same schema.
fix-config	0	Attempts to fix the configuration (ex: dropped tables) before doing any other updates. Used with --update.
frame-duration	1	The duration of the Scheduler's frame. in

name	1	The name of the Scheduler's frame, in which every configured Microbatch runs. Default is 300 seconds: '00:05:00'
resource-pool	1	The Vertica resource pool to run the Scheduler on. Default is 'general'.
config-refresh	1	The interval of time between Scheduler configuration refreshes. Default is 5 minutes: '00:05'
new-source-policy	1	The policy for new Sources to be scheduled during a frame. Options are: START, END, and FAIR. Default is 'FAIR'.
pushback-policy	1	
pushback-max-count	1	
auto-sync	1	Automatically update configuration based on metadata from the Kafka cluster
consumer-group-id	1	The Kafka consumer group id to report offsets to.
eof-timeout-ms	1	[DEPRECATED] This option has no effect.

## Scheduler tool options

The vkconfig script's scheduler tool lets you configure schedulers that continuously loads data from Kafka into Vertica. Use the scheduler tool to create, update, or delete a scheduler, defined by [config-schema](#) . If you do not specify a scheduler, commands apply to the default stream\_config scheduler.

### Syntax

```
vkconfig scheduler {--create | --read | --update | --drop} other_options...
```

#### --create

Creates a new scheduler. Cannot be used with [--delete](#) , [--read](#) , or [--update](#) .

#### --read

Outputs the current setting of the scheduler in JSON format. Cannot be used with [--create](#) , [--delete](#) , or [--update](#) .

#### --update

Updates the settings of the scheduler. Cannot be used with [--create](#) , [--delete](#) , or [--read](#) .

#### --drop

Drops the scheduler's schema. Dropping its schema deletes the scheduler. After you drop the scheduler's schema, you cannot recover it.

#### --add-operator *user\_name*

Grants a Vertica user account or role access to use and alter the scheduler. Requires the [--update](#) shared utility option.

#### --auto-sync {TRUE|FALSE}

When TRUE, Vertica automatically synchronizes scheduler source information at the interval specified in [--config-refresh](#) .

For details about what the scheduler synchronizes at each interval, see the "Validating Schedulers" and "Synchronizing Schedulers" sections in [Automatically consume data from Kafka with a scheduler](#) .

**Default:** TRUE

#### --config-refresh *HH:MM:SS*

The interval of time that the scheduler runs before synchronizing its settings and updating its cached metadata (such as changes made by using the [--update](#) option).

**Default:** 00:05:00

#### --consumer-group-id *id\_name*

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see [Monitoring Vertica message consumption with consumer groups](#) .

**Default:** *vertica\_database-name*

#### --dump

When you use this option along with the `--read` option, `vkconfig` outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through `vkconfig`. This option has no effect if not used with `--read`.

**`--eof-timeout-ms` *number of milliseconds***

If a COPY command does not receive any messages within the `eof-timeout-ms` interval, Vertica responds by ending that COPY statement.

See [Manually consume data from Kafka](#) for more information.

**Default:** 1 second

**`--fix-config`**

Repairs the configuration and re-creates any missing tables. Valid only with the `--update` shared configuration option.

**`--frame-duration` *HH:MM:SS***

The interval of time that all individual frames last with this scheduler. The scheduler must have enough time to run each microbatch (each of which execute a COPY statement). You can approximate the average available time per microbatch using the following equation:

$$\text{TimePerMicrobatch} = (\text{FrameDuration} * \text{Parallelism}) / \text{Microbatches}$$

This is just a rough estimate as there are many factors that impact the amount of time that each microbatch will be able to run.

The `vkconfig` utility warns you if the time allocated per microbatch is below 2 seconds. You usually should allocate more than two seconds per microbatch to allow the scheduler to load all of the data in the data stream.

**Note**

In versions of Vertica earlier than 10.0, the default frame duration was 10 seconds. In version 10.0, this default value was increased to 5 minutes in part to compensate for the removal of WOS. If you created your scheduler with the default frame duration in a version prior to 10.0, the frame duration is not updated to the new default value. In this case, consider adjusting the frame duration manually. See [Choosing a frame duration](#) for more information.

**Default:** 00:05:00

**`--message_max_bytes` *max\_message\_size***

Specifies the maximum size, in bytes, of a Kafka protocol batch message.

**Default:** 25165824

**`--new-source-policy` {FAIR|START|END}**

Determines how Vertica allocates resources to the newly added source, one of the following:

- FAIR: Takes the average length of time from the previous batches and schedules itself appropriately.
- START: All new sources start at the beginning of the frame. The batch receives the minimal amount of time to run.
- END: All new sources start at the end of the frame. The batch receives the maximum amount of time to run.

**Default:** FAIR

**`--operator` *username***

Allows the `dbadmin` to grant privileges to a previously created Vertica user or role.

This option gives the specified user all privileges on the scheduler instance and EXECUTE privileges on the `libkafka` library and all its UDxs. Granting operator privileges gives the user the right to read data off any source in any cluster that can be reached from the Vertica node.

The `dbadmin` must grant the user separate permission for them to have write privileges on the target tables.

Requires the `--create` shared utility option. Use the `--add-operator` option to grant operate privileges after the scheduler has been created.

To revoke privileges, use the `--remove-operator` option.

**`--remove-operator` *user\_name***

Removes access to the scheduler from a Vertica user account. Requires the `--update` shared utility option.

**`--resource-pool` *pool\_name***

The resource pool to be used by all queries executed by this scheduler. You must create this pool in advance.

**Default:** [GENERAL](#) pool

**Note**

The scheduler can use only one-fourth of GENERAL pool's [PLANNEDCONCURRENCY](#).

## --upgrade

Upgrades the existing scheduler and configuration schema to the current Vertica version. The upgraded version of the scheduler is not backwards compatible with earlier versions. To upgrade a scheduler to an alternate schema, use the [upgrade-to-schema](#) parameter. See [Updating schedulers after Vertica upgrades](#) for more information.

## --upgrade-to-schema *schema name*

Copies the scheduler's schema to a new schema specified by *schema name* and then upgrades it to be compatible with the current version of Vertica. Vertica does not alter the old schema. Requires the [--upgrade](#) scheduler utility option.

## --validation-type {ERROR|WARN|SKIP}

Renamed from [--skip-validation](#), specifies the level of validation performed on the scheduler. Invalid SQL syntax and other errors can cause invalid microbatches. Vertica supports the following validation types:

- ERROR: Cancel configuration or creation if validation fails.
- WARN: Proceed with task if validation fails, but display a warning.
- SKIP: Perform no validation.

For more information on validation, refer to [Automatically consume data from Kafka with a scheduler](#).

**Default:** ERROR

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

## Examples

These examples show how you can use the scheduler utility options.

Give a user, Jim, privileges on the StreamConfig scheduler. Specify that you are making edits to the stream\_config scheduler with the [--config-schema](#) option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --config-schema stream_config --add-operator Jim
```

Edit the default stream\_config scheduler so that every microbatch waits for data for one second before ending:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --update --eof-timeout-ms 1000
```

Upgrade the scheduler named `iot_scheduler_8.1` to a new scheduler named `iot_scheduler_9.0` that is compatible with the current version of Vertica:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --config-schema iot_scheduler_8.1 \
--upgrade-to-schema iot_scheduler_9.0
```

Drop the schema scheduler219a:

```
$ /opt/vertica/packages/kafka/bin/vkconfig scheduler --drop --config-schema scheduler219a --username dbadmin
```

Read the current setting of the options you can set using the scheduler tool for the scheduler defined in `weblogs.conf`.

```
$ vkconfig scheduler --read --conf weblog.conf
{
 "version":"v9.2.0", "frame_duration":"00:00:10", "resource_pool":"weblog_pool",
 "config_refresh":"00:05:00", "new_source_policy":"FAIR",
 "pushback_policy":"LINEAR", "pushback_max_count":5, "auto_sync":true,
 "consumer_group_id":null
}
```

## Cluster tool options

The vkconfig script's cluster tool lets you define the streaming hosts your scheduler connects to.

### Syntax

```
vkconfig cluster {--create | --read | --update | --delete} \
 [--cluster cluster_name] [other_options...]
```

### --create

Creates a new cluster. Cannot be used with [--delete](#), [--read](#), or [--update](#).

### --read

Outputs the settings of all clusters defined in the scheduler. This output is in JSON format. Cannot be used with [--create](#), [--delete](#), or [--update](#).

You can limit the output to specific clusters by supplying one or more cluster names in the `--cluster` option. You can also limit the output to clusters that contain one or more specific hosts using the `--hosts` option. Use commas to separate multiple values.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

#### **--update**

Updates the settings of `cluster_name`. Cannot be used with `--create`, `--delete`, or `--read`.

#### **--delete**

Deletes the cluster `cluster_name`. Cannot be used with `--create`, `--read`, or `--update`.

#### **--dump**

When you use this option along with the `--read` option, `vkconfig` outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through `vkconfig`. This option has no effect if not used with `--read`.

#### **--cluster `cluster_name`**

A unique, case-insensitive name for the cluster to operate on. This option is required for `--create`, `--update`, and `--delete`.

#### **--hosts `b1 : port` [, `b2 : port` ...]**

Identifies the broker hosts that you want to add, edit, or remove from a Kafka cluster. To identify multiple hosts, use a comma delimiter.

#### **--kafka\_conf ' `kafka_configuration_setting` '**

A JSON string of property/value pairs to pass directly to the `rdkafka`, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

#### **--kafka\_conf\_secret ' `kafka_configuration_setting` '**

Conceals sensitive configuration data that you must pass directly to the `rdkafka` library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

#### **--new-cluster `cluster_name`**

The updated name for the cluster. Requires the `--update` shared utility option.

#### **--validation-type {ERROR|WARN|SKIP}**

Specifies the level of validation performed on a created or updated cluster:

- ERROR - Cancel configuration or creation if `vkconfig` cannot validate that the cluster exists. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from `--skip-validation`.

See [Common vkconfig script options](#) for options that are available in all of the `vkconfig` tools.

#### Examples

This example shows how you can create the cluster, `StreamCluster1`, and assign two hosts:

```
$ /opt/vertica/packages/kafka/bin/vkconfig cluster --create --cluster StreamCluster1 \
 --hosts 10.10.10.10:9092,10.10.10.11:9092 \
 --conf myscheduler.config
```

This example shows how you can list all of the clusters associated with the scheduler defined in the `weblogs.conf` file:

```
$ vkconfig cluster --read --conf weblog.conf \
{ "cluster": "kafka_weblog", \
 "hosts": "kafka01.example.com:9092,kafka02.example.com:9092" }
```

#### Source tool options

Use the `vkconfig` script's source tool to create, update, or delete a source.

#### Syntax

```
vkconfig source {--create | --read | --update | --delete} \
 --source source_name [other_options...]
```

**--create**

Creates a new source. Cannot be used with `--delete` , `--read` , or `--update` .

**--read**

Outputs the current setting of the sources defined in the scheduler. The output is in JSON format. Cannot be used with `--create` , `--delete` , or `--update` .

By default this option outputs all of the sources defined in the scheduler. You can limit the output by using the `--cluster` , `--enabled` , `--partitions` , and `--source` options. The output will only contain sources that match the values in these options. The `--enabled` option can only have a true or false value. The `--source` option is case-sensitive.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

**--update**

Updates the settings of `source_name` . Cannot be used with `--create` , `--delete` , or `--read` .

**--delete**

Deletes the source named `source_name` . Cannot be used with `--create` , `--read` , or `--update` .

**--source *source\_name***

Identifies the source to create or alter in the scheduler's configuration. This option is case-sensitive. You can use any name you like for a new source. Most people use the name of the Kafka topic the scheduler loads its data from. This option is required for `--create` , `--update` , and `--delete` .

**--cluster *cluster\_name***

Identifies the cluster containing the source that you want to create or edit. You must have already defined this cluster in the scheduler.

**--dump**

When you use this option along with the `--read` option, `vkconfig` outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through `vkconfig`. This option has no effect if not used with `--read` .

**--enabled TRUE|FALSE**

When TRUE, the source is available for use.

**--new-cluster *cluster\_name***

Changes the cluster this source belongs to.

All sources referencing the old cluster source now target this cluster.

**Requires:** `--update` and `--source` options

**--new-source *source\_name***

Updates the name of an existing source to the name specified by this parameter.

**Requires:** `--update` shared utility option

**--partitions *count***

Sets the number of partitions in the source.

**Default:**

The number of partitions defined in the cluster.

**Requires:** `--create` and `--source` options

You must keep this consistent with the number of partitions in the Kafka topic.

Renamed from `--num-partitions` .

**--validation-type{ERROR|WARN|SKIP}**

Controls the validation performed on a created or updated source:

- ERROR - Cancel configuration or creation if `vkconfig` cannot validate the source. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from `--skip-validation` .

See [Common vkconfig script options](#) for options that are available in all of the `vkconfig` tools.

## Examples

The following examples show how you can create or update SourceFeed.

Create the source SourceFeed and assign it to the cluster, StreamCluster1 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --create --source SourceFeed \
 --cluster StreamCluster1 --partitions 3 \
 --conf myscheduler.conf
```

Update the existing source SourceFeed to use the existing cluster, StreamCluster2 in the scheduler defined by the myscheduler.conf config file:

```
$ /opt/vertica/packages/kafka/bin/vkconfig source --update --source SourceFeed \
 --new-cluster StreamCluster2 \
 --conf myscheduler.conf
```

The following example reads the sources defined in the scheduler defined by the weblog.conf file.

```
$ vkconfig source --read --conf weblog.conf
{
 "source": "web_hits", "partitions": 1, "src_enabled": true,
 "cluster": "kafka_weblog",
 "hosts": "kafka01.example.com:9092,kafka02.example.com:9092"}
}
```

## Target tool options

Use the target tool to configure a Vertica table to receive data from your streaming data application.

### Syntax

```
vkconfig target [--create | --read | --update | --delete] \
 [--target-table table --table_schema schema] \
 [other_options...]
```

#### **--create**

Adds a new target table for the scheduler. Cannot be used with **--delete**, **--read**, or **--update**.

#### **--read**

Outputs the targets defined in the scheduler. This output is in JSON format. Cannot be used with **--create**, **--delete**, or **--update**.

By default this option outputs all of the targets defined in the configuration schema. You can limit the output to specific targets by using the **--target-schema** and **--target-table** options. The vkconfig script only outputs targets that match the values you set in these options.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

#### **--update**

Updates the settings for the targeted table. Use with the **--new-target-schema** and **--new-target-table** options. Cannot be used with **--create**, **--delete**, or **--read**.

#### **--delete**

Removes the scheduler's association with the target table *table*. Cannot be used with **--create**, **--read**, or **--update**.

#### **--target-table *table***

The existing Vertica table for the scheduler to target. This option is required for **--create**, **--update**, and **--delete**.

#### **--target-schema *schema***

The existing Vertica schema containing the target table. This option is required for **--create**, **--update**, and **--delete**.

#### **--dump**

When you use this option along with the **--read** option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with **--read**.

#### **--new-target-schema *schema\_name***

Changes the schema containing the target table to a another existing schema.

**Requires:** **--update** option.

#### **--new-target-table *table\_name***

Changes the Vertica target table associated with this schema to a another existing table.

**Requires:** `--update` option.

### `--validation-type {ERROR|WARN|SKIP}`

Controls validation performed on a created or updated target:

- ERROR - Cancel configuration or creation if vkconfig cannot validate that the table exists. This is the default setting.
- WARN - Creates or updates the target if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from `--skip-validation` .

### Important

Avoid having columns with primary key restrictions in your target table. The scheduler stops loading data if it encounters a row that has a value which violates this restriction. If you must have a primary key restricted column, try to filter out any redundant values for that column in the streamed data before it is loaded by the scheduler.

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

### Examples

This example shows how you can create a target for the scheduler defined in the myscheduler.conf configuration file from public.streamtarget table:

```
$ /opt/vertica/packages/kafka/bin/vkconfig target --create \
--target-table streamtarget --conf myscheduler.conf
```

This example lists all of the targets in the scheduler defined in the weblog.conf configuration file.

```
$ vkconfig target --read --conf weblog.conf
{"target_schema":"public", "target_table":"web_hits"}
```

### Load spec tool options

The vkconfig script's load spec tool lets you provide parameters for a COPY statement that loads streaming data.

### Syntax

```
$ vkconfig load-spec [--create | --read | --update | --delete] \
[--load-spec spec-name] [other-options...]
```

#### `--create`

Creates a new load spec. Cannot be used with `--delete` , `--read` , or `--update` .

#### `--read`

Outputs the current settings of the load specs defined in the scheduler. This output is in JSON format. Cannot be used with `--create` , `--delete` , or `--update` .

By default, this option outputs all load specs defined in the scheduler. You can limit the output by supplying a single value or a comma-separated list of values to these options:

- `--load-spec`
- `--filters`
- `--uds-kv-parameters`
- `--parser`
- `--message-max-bytes`
- `--parser-parameters`

The vkconfig script only outputs the configuration of load specs that match the values you supply.

You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

#### `--update`

Updates the settings of *spec-name* . Cannot be used with `--create` , `--delete` , or `--read` .

#### `--delete`

Deletes the load spec named *spec-name* . Cannot be used with `--create` , `--read` , or `--update` .

#### `--load-spec spec-name`

A unique name for copy load spec to operate on. This option is required for `--create` , `--update` , and `--delete` .

#### `--dump`

When you use this option along with the `--read` option, `vkconfig` outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through `vkconfig`. This option has no effect if not used with `--read`.

**--filters " *filter-name* "**

A Vertica FILTER chain containing all of the UDFilters to use in the COPY statement. For more information on filters, refer to [Parsing custom formats](#).

**--message-max-bytes *max-size***

Specifies the maximum size, in bytes, of a Kafka protocol batch message.

**Default:** 25165824

**--new-load-spec *new-name***

A new, unique name for an existing load spec. Requires the `--update` parameter.

**--parser-parameters " *key = value* [...]"**

A list of parameters to provide to the parser specified in the `--parser` parameter. When you use a Vertica native parser, the scheduler passes these parameters to the COPY statement where they are in turn passed to the parser.

**--parser *parser-name***

Identifies a Vertica UDFParser to use with a specified target. This parser is used within the COPY statement that the scheduler runs to load data. If you are using a Vertica native parser, the values supplied to the `--parser-parameters` option are passed through to the COPY statement.

**\*\*Default:\*\*** KafkaParser

**--uds-kv-parameters *key = value* [...]**

A comma separated list of key value pairs for the user-defined source.

**--validation-type {ERROR|WARN|SKIP}**

Specifies the validation performed on a created or updated load spec, to one of the following:

- **ERROR** : Cancel configuration or creation if `vkconfig` cannot validate the load spec. This is the default setting.
- **WARN** : Proceed with task if validation fails, but display a warning.
- **SKIP** : Perform no validation.

Renamed from `--skip-validation`.

See [Common vkconfig script options](#) for options that are available in all of the `vkconfig` tools.

Examples

These examples show how you can use the Load Spec utility options.

Create load spec `Streamspec1` :

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --create --load-spec Streamspec1 --conf myscheduler.conf
```

Rename load spec `Streamspec1` to `Streamspec2` :

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Streamspec1 \
 --new-load-spec Streamspec2 \
 --conf myscheduler.conf
```

Update load spec `Filterspec` to use the `KafkaInsertLengths` filter and a custom decryption filter:

```
$ /opt/vertica/packages/kafka/bin/vkconfig load-spec --update --load-spec Filterspec \
 --filters "KafkaInsertLengths() DecryptFilter(parameter=Key)" \
 --conf myscheduler.conf
```

Read the current settings for load spec `streamspec1` :

```
$ vkconfig load-spec --read --load-spec streamspec1 --conf weblog.conf
{
 "load_spec": "streamspec1",
 "filters": null,
 "parser": "KafkaParser",
 "parser_parameters": null,

}
```

Microbatch tool options

The vkconfig script's microbatch tool lets you configure a scheduler's microbatches.

## Syntax

```
vkconfig microbatch {--create | --read | --update | --delete} \
 [--microbatch microbatch_name] [other_options...]
```

### --create

Creates a new microbatch. Cannot be used with `--delete`, `--read`, or `--update`.

### --read

Outputs the current settings of all microbatches defined in the scheduler. This output is in JSON format. Cannot be used with `--create`, `--delete`, or `--update`.

You can limit the output to specific microbatches by using the `--consumer-group-id`, `--enabled`, `--load-spec`, `--microbatch`, `--rejection-schema`, `--rejection-table`, `--target-schema`, `--target-table`, and `--target-columns` options. The `--enabled` option only accepts a true or false value. You can use LIKE wildcards in these options. See [LIKE](#) for more information about using wildcards.

### --update

Updates the settings of *microbatch\_name*. Cannot be used with `--create`, `--delete`, or `--read`.

### --delete

Deletes the microbatch named *microbatch\_name*. Cannot be used with `--create`, `--read`, or `--update`.

### --microbatch *microbatch\_name*

A unique, case insensitive name for the microbatch. This option is required for `--create`, `--update`, and `--delete`.

### --add-source-cluster *cluster\_name*

The name of a cluster to assign to the microbatch you specify with the `--microbatch` option. You can use this parameter once per command. You can also use it with `--update` to add sources to a microbatch. You can only add sources from the same cluster to a single microbatch. Requires `--add-source`.

### --add-source *source\_name*

The name of a source to assign to this microbatch. You can use this parameter once per command. You can also use it with `--update` to add sources to a microbatch. Requires `--add-source-cluster`.

### --cluster *cluster\_name*

The name of the cluster to which the `--offset` option applies. Only required if the microbatch defines more than one cluster or the `--source` parameter is supplied. Requires the `--offset` option.

### --consumer-group-id *id\_name*

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see [Monitoring Vertica message consumption with consumer groups](#).

**Default:** `vertica_database-name`

### --dump

When you use this option along with the `--read` option, vkconfig outputs the Vertica query it would use to retrieve the data, rather than outputting the data itself. This option is useful if you want to access the data from within Vertica without having to go through vkconfig. This option has no effect if not used with `--read`.

### --enabled TRUE|FALSE

When TRUE, allows the microbatch to execute.

### --load-spec *loadspect\_name*

The load spec to use while processing this microbatch.

### --max-parallelism *max\_num\_loads*

The maximum number of simultaneous COPY statements created for the microbatch. The scheduler dynamically splits a single microbatch with multiple partitions into *max\_num\_loads* COPY statements with fewer partitions.

This option allows you to:

- Control the transaction size.
- Optimize your loads according to your scheduler's [scheduler's resource pool](#) settings, such as [PLANNEDCONCURRENCY](#).

### --new-microbatch *updated\_name*

The updated name for the microbatch. Requires the `--update` option.

**--offset *partition\_offset* [...]**

The offset of the message in the source where the microbatch starts its load. If you use this parameter, you must supply an offset value for each partition in the source or each partition you list in the **--partition** option.

You can use this option to skip some messages in the source or reload previously read messages. See [Special Starting Offset Values](#) below for more information.

**Important**

You cannot set an offset for a microbatch while the scheduler is running. If you attempt to do so, the vkconfig utility returns an error. Use the shutdown utility to shut the scheduler down before setting an offset for a microbatch.

**--partition *partition* [...]**

One or more partitions to which the offsets given in the **--offset** option apply. If you supply this option, then the offset values given in the **--offset** option applies to the partitions you specify. Requires the **--offset** option.

**--rejection-schema *schema\_name***

The existing Vertica schema that contains a table for storing rejected messages.

**--rejection-table *table\_name***

The existing Vertica table that stores rejected messages.

**--remove-source-cluster *cluster\_name***

The name of a cluster to remove from this microbatch. You can use this parameter once per command. Requires **--remove-source** .

**--remove-source *source\_name***

The name of a source to remove from this microbatch. You can use this parameter once per command. You can also use it with **--update** to remove multiple sources from a microbatch. Requires **--remove-source-cluster** .

**--source *source\_name***

The name of the source to which the offset in the **--offset** option applies. Required when the microbatch defines more than one source or the **--cluster** parameter is given. Requires the **--offset** option.

**--target-columns *column\_expression***

A column expression for the target table, where *column\_expression* can be a comma-delimited list of columns or a complete expression.

See the COPY statement [Parameters](#) for a description of column expressions.

**--target-schema *schema\_name***

The existing Vertica target schema associated with this microbatch.

**--target-table *table\_name***

The name of a Vertica table corresponding to the target. This table must belong to the target schema.

**--validation-type {ERROR|WARN|SKIP}**

Controls the validation performed on a created or updated microbatch:

- ERROR - Cancel configuration or creation if vkconfig cannot validate the microbatch. This is the default setting.
- WARN - Proceed with task if validation fails, but display a warning.
- SKIP - Perform no validation.

Renamed from **--skip-validation** .

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

**Special starting offset values**

The *start\_offset* portion of the **stream** parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- -2 tells the scheduler to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.
- -3 tells the scheduler to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See [Monitoring Vertica message consumption with consumer groups](#) for more information.

**Examples**

This example shows how you can create the microbatch, mbatch1. This microbatch identifies the schema, target table, load spec, and source for the microbatch:

```
$ /opt/vertica/packages/kafka/bin/vkconfig microbatch --create --microbatch mbatch1 \
 --target-schema public \
 --target-table BatchTarget \
 --load-spec Filterspec \
 --add-source SourceFeed \
 --add-source-cluster StreamCluster1 \
 --conf myscheduler.conf
```

This example demonstrates listing the current settings for the microbatches in the scheduler defined in the weblog.conf configuration file.

```
$ vkconfig microbatch --read --conf weblog.conf
{
 "microbatch": "weblog",
 "target_columns": null,
 "rejection_schema": null,
 "rejection_table": null,
 "enabled": true,
 "consumer_group_id": null,
 "load_spec": "weblog_load",
 "filters": null,
 "parser": "KafkaJSONParser",
 "parser_parameters": null,
 "load_method": "TRICKLE",
 "message_max_bytes": null,
 "uds_kv_parameters": null,
 "target_schema": "public",
 "target_table": "web_hits",
 "source": "web_hits",
 "partitions": 1,
 "src_enabled": true,
 "cluster": "kafka_weblog",
 "hosts": "kafka01.example.com:9092,kafka02.example.com:9092"
}
```

## Launch tool options

Use the vkconfig script's launch tool to assign a name to a scheduler instance.

### Syntax

```
vkconfig launch [options...]
```

#### **--enable-ssl** {true|false}

(Optional) Enables SSL authentication between Kafka and Vertica . For more information, refer to [TLS/SSL encryption with Kafka](#) .

#### **--ssl-ca-alias** *alias*

The user-defined alias of the root certifying authority you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.

#### **--ssl-key-alias** *alias*

The user-defined alias of the key/certificate pair you are using to authenticate communication between Vertica and Kafka. This parameter is used only when SSL is enabled.

#### **--ssl-key-password** *password*

The password used to create your SSL key. This parameter is used only when SSL is enabled.

#### **--instance-name** *name*

(Optional) Allows you to name the process running the scheduler. You can use this command when viewing the scheduler\_history table, to find which instance is currently running.

#### **--refresh-interval** *hours*

(Optional) The time interval at which the connection between Vertica and Kafka is refreshed (24 hours by default).

#### **--kafka\_conf** ' *kafka\_configuration\_setting* '

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#) .

#### **--kafka\_conf\_secret** ' *kafka\_configuration\_setting* '

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf` .

Values passed to this parameter are not logged or stored in system tables.

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

## Examples

This example shows how you can launch the scheduler defined in the myscheduler.conf config file and give it the instance name PrimaryScheduler:

```
$ nohup /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name PrimaryScheduler \
 --conf myscheduler.conf >/dev/null 2>&1 &
```

This example shows how you can launch an instance named SecureScheduler with SSL enabled:

```
$ nohup /opt/vertica/packages/kafka/bin/vkconfig launch --instance-name SecureScheduler --enable-SSL true \
--ssl-ca-alias authenticcert --ssl-key-alias ourkey \
--ssl-key-password secret \
--conf myscheduler.conf \
>/dev/null 2>&1 &
```

## Shutdown tool options

Use the vkconfig script's shutdown tool to terminate one or all Vertica schedulers running on a host. Always run this command before restarting a scheduler to ensure the scheduler has shutdown correctly.

### Syntax

```
vkconfig shutdown [options...]
```

See [Common vkconfig script options](#) for options that are available in all vkconfig tools.

### Examples

To terminate all schedulers running on a host, use the **shutdown** command with no options:

```
$ /opt/vertica/packages/kafka/bin/vkconfig shutdown
```

Use the **--conf** or **--config-schema** option to specify a scheduler to shut down. The following command terminates the scheduler that was launched with the same **--conf myscheduler.conf** option:

```
$ /opt/vertica/packages/kafka/bin/vkconfig shutdown --conf myscheduler.conf
```

## Statistics tool options

The statistics tool lets you access the history of microbatches that your scheduler has run. This tool outputs the log of the microbatches in JSON format to the standard output. You can use its options to filter the list of microbatches to get just the microbatches that interest you.

### Note

The statistics tool can sometimes produce confusing output if you have altered the scheduler configuration over time. For example, suppose you have microbatch-a target a table. Later, you change the scheduler's configuration so that microbatch-b targets the table. Afterwards, you run the statistics tool and filter the microbatch log based on target table. Then the log output will show entries from both microbatch-a and microbatch-b.

### Syntax

```
vkconfig statistics [options]
```

**--cluster " *cluster* "[" *cluster2* "...]**

Only return microbatches that retrieved data from a cluster whose name matches one in the list you supply.

**--dump**

Instead of returning microbatch data, return the SQL query that vkconfig would execute to extract the data from the scheduler tables. You can use this option if you want use a Vertica client application to get the microbatch log instead of using vkconfig's JSON output.

**--from-timestamp " *timestamp* "**

Only return microbatches that began after *timestamp*. The timestamp value is in *yyyy -[ m ] m -[ d ] d hh : mm : ss* format.

Cannot be used in conjunction with **--last**.

**--last *number***

Returns the *number* most recent microbatches that meet all other filters. Cannot be used in conjunction with **--from-timestamp** or **--to-timestamp**.

**--microbatch " *name* "[" *name2* "...]**

Only return microbatches whose name matches one of the names in the comma-separated list.

**--partition *partition#* [, *partition#2* ...]**

Only return microbatches that accessed data from the topic partition that matches ones of the values in the partition list.

**--source " *source* "[" *source2* "...]**

Only return microbatches that accessed data from a source whose name matches one of the names in the list you supply to this argument.

**--target-schema "schema"["schema2"...]**

Only return microbatches that wrote data to the Vertica schemas whose name matches one of the names in the target schema list argument.

**--target-table "table"["table2"...]**

Only return microbatches that wrote data to Vertica tables whose name match one of the names in the target schema list argument.

**--to-timestamp " *timestamp* "**

Only return microbatches that began before *timestamp* . The timestamp value is in `yyyy-[ m ] m -[ d ] d hh : mm : ss` format.

Cannot be used in conjunction with `--last` .

See [Common vkconfig script options](#) for options that are available in all of the vkconfig tools.

Usage considerations

- You can use LIKE wildcards in the values you supply to the `--cluster` , `--microbatch` , `--source` , `--target-schema` , and `--target-table` arguments. This feature lets you match partial strings in the microbatch data. See [LIKE](#) for more information about using wildcards.
- The string comparisons for the `--cluster` , `--microbatch` , `--source` , `--target-schema` , and `--target-table` arguments are case-insensitive.
- The date and time values you supply to the `--from-timestamp` and `--to-timestamp` arguments use the [java.sql.timestamp](#) format for parsing the value. This format's parsing can accept values that you may consider invalid and would expect it to reject. For example, if you supply a timestamp of 01-01-2018 24:99:99, the Java timestamp parser silently converts the date to 2018-01-02 01:40:39 instead of returning an error.

Examples

This example gets the last microbatch that the scheduler defined in the weblog.conf file ran:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.793000", "batch_start":"2018-11-06 09:42:00.176747",
"batch_end":"2018-11-06 09:42:00.437787", "source_duration":"00:00:00.214314",
"consecutive_error_count":null, "transaction_id":45035996274513069,
"frame_start":"2018-11-06 09:41:59.949", "frame_end":null}
```

If your scheduler is reading from more than partition, the `--last 1` option lists the last microbatch from each partition:

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":0,
"start_offset":-2, "end_offset":-2, "end_reason":"DEADLINE",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:09.950127",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4387, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.220329",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":2,
"start_offset":1603, "end_offset":1652, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4383, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.318997",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":3,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4375, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.219543",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}

```

You can use the `--partition` argument to get just the partitions you want:

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --partition 2 --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":2,
"start_offset":1603, "end_offset":1652, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4383, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.318997",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}

```

If your scheduler reads from more than one source, the `--last 1` option outputs the last microbatch from each source:

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --last 1 --conf weblog.conf
{"microbatch":"weberrors", "target_schema":"public", "target_table":"web_errors",
"source_name":"web_errors", "source_cluster":"kafka_weblog",
"source_partition":0, "start_offset":10000, "end_offset":9999,
"end_reason":"END_OF_STREAM", "end_reason_message":null,
"partition_bytes":0, "partition_messages":0, "timeslice":"00:00:04.909000",
"batch_start":"2018-11-06 10:58:02.632624",
"batch_end":"2018-11-06 10:58:03.058663", "source_duration":"00:00:00.220618",
"consecutive_error_count":null, "transaction_id":45035996274523991,
"frame_start":"2018-11-06 10:58:02.394", "frame_end":null}
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:09.128000", "batch_start":"2018-11-06 10:58:03.322852",
"batch_end":"2018-11-06 10:58:03.63047", "source_duration":"00:00:00.226493",
"consecutive_error_count":null, "transaction_id":45035996274524004,
"frame_start":"2018-11-06 10:58:02.394", "frame_end":null}

```

You can use wildcards to enable partial matches. This example demonstrates getting the last microbatch for all microbatches whose names end with "log":

```

~$ /opt/vertica/packages/kafka/bin/vkconfig statistics --microbatch "%log" \
--last 1 --conf weblog.conf
{"microbatch":"weblog", "target_schema":"public", "target_table":"web_hits",
"source_name":"web_hits", "source_cluster":"kafka_weblog", "source_partition":0,
"start_offset":80000, "end_offset":79999, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":0, "partition_messages":0,
"timeslice":"00:00:04.874000", "batch_start":"2018-11-06 11:37:16.17198",
"batch_end":"2018-11-06 11:37:16.460844", "source_duration":"00:00:00.213129",
"consecutive_error_count":null, "transaction_id":45035996274529932,
"frame_start":"2018-11-06 11:37:15.877", "frame_end":null}

```

To get microbatches from a specific period of time, use the `--from-timestamp` and `--to-timestamp` arguments. This example gets the microbatches that read from partition #2 between 12:52:30 and 12:53:00 on 2018-11-06 for the scheduler defined in `iot.conf`.

```

$ /opt/vertica/packages/kafka/bin/vkconfig statistics --partition 1 \
--from-timestamp "2018-11-06 12:52:30" \
--to-timestamp "2018-11-06 12:53:00" --conf iot.conf
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1604, "end_offset":1653, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4387, "partition_messages":50,
"timeslice":"00:00:09.842000", "batch_start":"2018-11-06 12:52:49.387567",
"batch_end":"2018-11-06 12:52:59.400219", "source_duration":"00:00:00.220329",
"consecutive_error_count":null, "transaction_id":45035996274537015,
"frame_start":"2018-11-06 12:52:49.213", "frame_end":null}
{"microbatch":"iotlog", "target_schema":"public", "target_table":"iot_data",
"source_name":"iot_data", "source_cluster":"kafka_iot", "source_partition":1,
"start_offset":1554, "end_offset":1603, "end_reason":"END_OF_STREAM",
"end_reason_message":null, "partition_bytes":4371, "partition_messages":50,
"timeslice":"00:00:09.788000", "batch_start":"2018-11-06 12:52:38.930428",
"batch_end":"2018-11-06 12:52:48.932604", "source_duration":"00:00:00.231709",
"consecutive_error_count":null, "transaction_id":45035996274536981,
"frame_start":"2018-11-06 12:52:38.685", "frame_end":null}

```

This example demonstrates using the `--dump` argument to get the SQL statement `vkconfig` executed to retrieve the output from the previous example:

```
$ /opt/vertica/packages/kafka/bin/vkconfig statistics --dump --partition 1 \
 --from-timestamp "2018-11-06 12:52:30" \
 --to-timestamp "2018-11-06 12:53:00" --conf iot.conf
SELECT microbatch, target_schema, target_table, source_name, source_cluster,
source_partition, start_offset, end_offset, end_reason, end_reason_message,
partition_bytes, partition_messages, timeslice, batch_start, batch_end,
last_batch_duration AS source_duration, consecutive_error_count, transaction_id,
frame_start, frame_end FROM "iot_sched".stream_microbatch_history WHERE
(source_partition = '1') AND (frame_start >= '2018-11-06 12:52:30.0') AND
(frame_start < '2018-11-06 12:53:00.0') ORDER BY frame_start DESC, microbatch,
source_cluster, source_name, source_partition;
```

## Sync tool options

The sync utility immediately updates all source definitions by querying the Kafka cluster's brokers defined by the source. By default, it updates all of the sources defined in the target schema. To update just specific sources, use the `--source` and `--cluster` options to specify which sources to update.

## Syntax

```
vkconfig sync [options...]
```

### `--source source_name`

The name of the source sync. This source must already exist in the target schema.

### `--cluster cluster_name`

Identifies the cluster containing the source that you want to sync. You must have already defined this cluster in the scheduler.

### `--kafka_conf ' kafka_configuration_setting '`

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

### `--kafka_conf_secret ' kafka_configuration_setting '`

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

See the [Common vkconfig script options](#) for options available in all of the vkconfig tools..

## Kafka function reference

This section lists the functions that make up Vertica's Kafka integration feature.

In this section

- [KafkaAvroParser](#)
- [KafkaCheckBrokers](#)
- [KafkaExport](#)
- [KafkaJSONParser](#)
- [KafkaListManyTopics](#)
- [KafkaListTopics](#)
- [KafkaOffsets](#)
- [KafkaParser](#)
- [KafkaSource](#)
- [KafkaTopicDetails](#)

### KafkaAvroParser

The KafkaAvroParser parses Avro-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

## Syntax

```
KafkaAvroParser(param=value[...])
```

### `enforce_length`

When set to TRUE, rejects the row if any value is too wide to fit into its column. When using the default setting (FALSE), the parser truncates any value that is too wide to fit within the column's maximum width.

#### **reject\_on\_materialized\_type\_error**

When set to TRUE, rejects the row if it contains a materialized column value that cannot be mapped into the materialized column's data type.

#### **flatten\_maps**

If set to TRUE, flattens all Avro maps.

#### **flatten\_arrays**

If set to TRUE, flattens Avro arrays.

#### **flatten\_records**

If set to TRUE, flattens all Avro records.

#### **external\_schema**

The schema of the Avro file as a JSON string. If this parameter is not specified, the parser assumes that each message has the schema on it. If you are using a schema registry, do not use this parameter.

#### **codec**

The codec in which the Avro file was written. Valid values are:

- **default** : Data is not compressed and codec is not needed
- **deflate** : Data is compressed using the deflate codec
- **snappy** : Snappy compression

#### **Note**

This option is mainly provided for backwards compatibility. You usually have Kafka compress data at the message level, and have KafkaSource decompress the message for you.

#### **with\_metadata**

If set to TRUE, messages include Avro datum, schema, and object metadata. By default, the KafkaAvroParser parses messages without including schema and metadata. If you enable this parameter, write your messages using the Avro API and confirm they contain only Avro datum. The default value is FALSE.

#### **schema\_registry\_url**

Required, the URL of the Confluent schema registry. This parameter is required to load data based on a schema registry version. If you are using an external schema, do not use this parameter. For more information, refer to [Avro Schema Registry](#).

#### **Note**

TLS connections must use the HTTPS protocol.

#### **schema\_registry\_ssl\_ca\_path**

Required for TLS connections, the path on the Vertica node's file system to a directory containing one or more hashed certificate authority (CA) certificates that signed the schema registry's server certificate. Each Vertica node must store hashed CA certificates on the same path.

Important

In some circumstances, you might receive a validation error stating that the KafkaAvroParser cannot locate your CA certificate. To correct this error, store your CA certificate in your operating system's default bundle. For example, store the CA certificate in `/etc/pki/tls/certs/ca-bundle.crt` on Red Hat operating systems.

For details on hashed CA certificates, see [Hashed CA Certificates](#).

#### **schema\_registry\_ssl\_cert\_path**

Path on the Vertica node's file system to a client certificate issued by a certificate authority (CA) that the schema registry trusts.

#### **schema\_registry\_ssl\_key\_path**

Path on the Vertica server file system to the private key for the client certificate defined with `schema_registry_ssl_cert_path`.

#### **schema\_registry\_ssl\_key\_password\_path**

Path on the Vertica server file system to the optional password for the private key defined with `schema_registry_ssl_key_path`.

#### **schema\_registry\_subject**

In the schema registry, the subject of the schema to use for data loading.

## schema\_registry\_version

In the schema registry, the version of the schema to use for data loading.

## key\_separator

Sets the character to use as the separator between keys.

## Data types

KafkaAvroParser supports the same data types as the [favroparser](#). For details, see [Avro data](#).

## Example

The following example demonstrates loading data from Kafka in an Avro format. The statement:

- Loads data into an existing flex table named weather\_logs.
- Copies data from the default Kafka broker (running on the local system on port 9092).
- The source is named temperature.
- The source has a single partition.
- The load starts from offset 0.
- The load ends either after 10 seconds or the load reaches the end of the source, whichever occurs first.
- The KafkaAvroParser does not flatten any arrays, maps, or records it finds in the source.
- The schema for the data is provided in the statement as a JSON string. It defines a record type named Weather that contains fields for a station name, a time, and a temperature.
- Rejected rows of data are saved to a table named t\_rejects1.

```
=> COPY weather_logs
SOURCE KafkaSource(stream='temperature|0|0', stop_on_eof=true,
 duration=interval '10 seconds')
PARSER KafkaAvroParser(flatten_arrays=False, flatten_maps=False, flatten_records=False,
 external_schema=E'{"type":"record","name":"Weather","fields":'
 '{"name":"station","type":"string"},'
 '{"name":"time","type":"long"},'
 '{"name":"temp","type":"int"}]}'
REJECTED DATA AS TABLE "t_rejects1";
```

## Hashed CA certificates

Some parameters like [schema\\_registry\\_ssl\\_ca\\_path](#) require hashed CA certificates rather than the CA certificates themselves. A hashed CA certificate is a [symbolic link](#) to the original CA certificate. This symbolic link must have the following naming scheme:

```
CA_hash.0
```

For example, if the hash for [ca\\_cert.pem](#) is [9741086f](#), the hashed CA certificate would be [9741086f.0](#), a symbolic link to [ca\\_cert.pem](#).

For details, see the OpenSSL [1.1](#) or [1.0](#) documentation.

## Hashing CA certificates

The procedure for hashing CA certificates varies between versions of [openssl](#). You can find your version of [openssl](#) with:

```
$ openssl version
```

For [openssl](#) 1.1 or higher, use [openssl rehash](#). For example, if the directory [/my\\_ca\\_certs/](#) contains [ca\\_cert.pem](#), you can hash and symbolically link to it with:

```
$ openssl rehash /my_ca_certs/
```

This adds the hashed CA certificate to the directory:

```
$ ls -l
total 8
lrwxrwxrwx 1 ver ver 8 Mar 13 14:41 9da13359.0 -> ca_cert.pem
-rw-r--r-- 1 ver ver 1245 Mar 13 14:41 ca_cert.pem
```

For [openssl](#) 1.0, you can use [openssl x509 -hash -noout -in ca\\_cert.pem](#) to retrieve the hash and then create a symbolic link to the CA certificate. For example:

1. Run the following command to retrieve the hash of the CA certificate [ca\\_cert.pem](#) :

```
$ openssl x509 -hash -noout -in /my_ca_certs/ca_cert.pem
9741086f
```

2. Create a symbolic link to `/my_ca_certs/ca_cert.pem` :

```
$ ln /my_ca_certs/ca_cert.pem /my_ca_certs/9741086f.0
```

This adds the hashed CA certificate to the directory:

```
$ ls -l
total 8
-rw-r--r-- 2 ver ver 1220 Mar 13 13:41 9741086f.0 -> ca_cert.pem
-rw-r--r-- 2 ver ver 1220 Mar 13 13:41 ca_cert.pem
```

## KafkaCheckBrokers

Retrieves information about the brokers in a Kafka cluster. This function is intended mainly for internal use—it is used by the streaming job scheduler to get the list of brokers in the Kafka cluster. You can call the function to determine which brokers Vertica knows about.

### Syntax

```
KafkaCheckBrokers(USING PARAMETERS brokers='hostname:port[,hostname2:port...]'
 [, kafka_conf='kafka_configuration_setting']
 [, timeout=timeout_sec])
```

### brokers

The host name and port number of a broker in the Kafka cluster used to retrieve the list of brokers. You can supply more than one broker as a comma-separated list. If the list includes brokers from more than one Kafka cluster, the cluster containing the last host in the list is queried.

### kafka\_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

### kafka\_conf\_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

### timeout

Integer number of seconds to wait for a response from the Kafka cluster.

### Example

```
=> SELECT KafkaCheckBrokers(USING PARAMETERS brokers='kafka01.example.com:9092')
 OVER ();
broker_id | hostname | port
-----+-----+-----
2 | kafka03.example.com | 9092
1 | kafka02.example.com | 9092
3 | kafka04.example.com | 9092
0 | kafka01.example.com | 9092
(4 rows)
```

## KafkaExport

Sends Vertica data to Kafka.

If Vertica successfully exports all of the rows of data to Kafka, this function returns zero rows. You can use the output of this function to copy failed messages to a secondary table for evaluation and reprocessing.

### Syntax

```
SELECT KafkaExport(partitionColumn, keyColumn, valueColumn
 USING PARAMETERS brokers='host[:port][,host...]',
 topic='topicname'
 [,kafka_conf='kafka_configuration_setting']
 [,kafka_topic_conf='kafka_configuration_setting']
 [,kafka_conf_secret='kafka_configuration_setting']
 [,fail_on_conf_parse_error=Boolean])
OVER (partition_clause) FROM table;
```

## Parameters

### ***partitionColumn***

The target partition for the export. If you set this value to NULL, Vertica uses the default partitioning scheme. You can use the partition argument to send messages to partitions that map to Vertica segments.

### ***keyColumn***

The user defined key value associated with the valueColumn. Use NULL to skip this argument.

### ***valueColumn***

The message itself. The column is a LONG VARCHAR, allowing you to send up to 32MB of data to Kafka. However, Kafka may impose its own limits on message size.

### **brokers**

A string containing a comma-separated list of one or more host names or IP addresses (with optional port number) of brokers in the Kafka cluster.

### **topic**

The Kafka topic to which you are exporting.

### **kafka\_conf**

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

### **kafka\_topic\_conf**

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets topic-level configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

### **kafka\_conf\_secret**

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as [kafka\\_conf](#).

Values passed to this parameter are not logged or stored in system tables.

### **fail\_on\_conf\_parse\_error**

Determines whether the function fails when [kafka\\_conf](#) contains incorrectly formatted options and values, or invalid configuration properties.

**Default Value** : FALSE

For accepted option and value formats, see [Directly setting Kafka library options](#).

For a list of valid configuration properties, see the [rdkafka GitHub repository](#).

## Example

The following example converts each row from the `iot_report` table into a JSON object, and exports it to a Kafka topic named `iot-report`.

The `iot_report` table contains the following columns and data:

```
=> SELECT * FROM iot_report;
server | date | location | id
-----+-----+-----+-----
 1 | 2016-10-11 04:09:28 | -14.86058, 112.75848 | 70982027
 1 | 2017-07-02 12:37:48 | -21.42197, -127.17672 | 49494918
 2 | 2017-01-20 03:05:24 | 37.17372, 136.14026 | 36670100
 2 | 2017-07-29 11:38:37 | -38.99517, 171.72671 | 52049116
 1 | 2017-10-19 14:04:33 | -71.72156, -36.27381 | 94328189
(5 rows)
```

To build the KafkaExport function, provide the following values to define the Kafka message:

- **partitionColumn**: Use the `server` column. Because the `server` column values are one-based and Kafka partitions are zero-based, subtract 1 from the `server` value.
- **keyColumn**: Use the `id` column. This requires that you [explicitly cast](#) the `id` value to a VARCHAR type.
- **valueColumn**: Each message formats the date and location columns as the key/value pairs in the exported JSON object.

To convert these rows to JSON format, use the [ROW](#) function to convert the date and location columns to structured data. Then, pass the [ROW](#) function to the [TO\\_JSON](#) function to encode the data structure as a JSON object.

Complete the remaining required function arguments and execute the KafkaExport function. If it succeeds, it returns 0 rows:

```
=> SELECT KafkaExport(server - 1, id::VARCHAR, TO_JSON(ROW(date, location))
 USING PARAMETERS brokers='broker01:9092,broker02:9092',
 topic='iot-results')
OVER (PARTITION BEST)
FROM iot_report;
partition | key | message | failure_reason
-----+-----+-----+-----
(0 rows)
```

Use [kafkacat](#) to verify that the consumer contains the JSON-formatted data in the iot-results topic:

```
$ /opt/vertica/packages/kafka/bin/kafkacat -C -t iot-results -b broker01:9092,broker02:9092
{"date":"2017-01-20 03:05:24","location":" 37.17372, 136.14026 "}
{"date":"2017-07-29 11:38:37","location":" -38.99517, 171.72671 "}
{"date":"2016-10-11 04:09:28","location":" -14.86058, 112.75848 "}
{"date":"2017-10-19 14:04:33","location":" -71.72156, -36.27381 "}
{"date":"2017-07-02 12:37:48","location":" -21.42197, -127.17672 "}
```

See also

[Producing data using KafkaExport](#)

KafkaJSONParser

The KafkaJSONParser parses JSON-formatted Kafka messages and loads them into a regular Vertica table or a Vertica flex table.

Syntax

```
KafkaJSONParser(
 [enforce_length=Boolean]
 [, flatten_maps=Boolean]
 [, flatten_arrays=Boolean]
 [, start_point=string]
 [, start_point_occurrence=integer]
 [, omit_empty_keys=Boolean]
 [, reject_on_duplicate=Boolean]
 [, reject_on_materialized_type_error=Boolean]
 [, reject_on_empty_key=Boolean]
 [, key_separator=char]
 [, suppress_nonalphanumeric_key_chars=Boolean]
)
```

### enforce\_length

If set to TRUE, rejects the row if data being loaded is too wide to fit into its column. Defaults to FALSE, which truncates any data that is too wide to fit into its column.

**flatten\_maps**

If set to TRUE, flattens all JSON maps.

**flatten\_arrays**

If set to TRUE, flattens JSON arrays.

**start\_point**

Specifies the key in the JSON data that the parser should parse. The parser only extracts data that is within the value associated with the **start\_point** key. It parses the values of all instances of the **start\_point** key within the data.

**start\_point\_occurrence**

Integer value indicating which the occurrence of the key specified by the **start\_point** parameter where the parser should begin parsing. For example, if you set this value to 4, the parser will only begin loading data from the fifth occurrence of the **start\_point** key. Only has an effect if you also supply the **start\_point** parameter.

**omit\_empty\_keys**

If set to TRUE, omits any key from the load data that does not have a value set.

**reject\_on\_duplicate**

If set to TRUE, rejects the row that contains duplicate key names. Key names are case-insensitive, so the keys "mykey" and "MyKey" are considered duplicates.

**reject\_on\_materialized\_type\_error**

If set to TRUE, rejects the row if the data includes keys matching an existing materialized column and has a key that cannot be mapped into the materialized column's data type.

**reject\_on\_empty\_key**

If set to TRUE, rejects any row containing a key without a value.

**key\_separator**

A single character to use as the separator between key values instead of the default period ( . ) character.

**suppress\_nonalphanumeric\_key\_chars**

If set to TRUE, replaces all non-alphanumeric characters in JSON key values with an underscore ( \_ ) character.

See [JSON data](#) for more information.

The following example demonstrates loading JSON data from Kafka. The parameters in the statement define to the load to:

- Load data into the pre-existing table named logs.
- The KafkaSource streams the data from a single partition in the source called server\_log.
- The Kafka broker for the data load is running on the host named kafka01 on port 9092.
- KafkaSource stops loading data after either 10 seconds or on reaching the end of the stream, whichever happens first.
- The KafkJSONParser flattens any arrays or maps in the JSON data.

```
=> COPY logs SOURCE KafkaSource(stream='server_log|0|0',
 stop_on_eof=true,
 duration=interval '10 seconds',
 brokers='kafka01:9092')
PARSER KafkJSONParser(flatten_arrays=True, flatten_maps=True);
```

**KafkaListManyTopics**

Retrieves information about all topics from a Kafka broker. This function lists all of the topics defined in the Kafka cluster as well the number of partitions it contains and which brokers serve the topic.

**Syntax**

```
KafkaListManyTopics('broker:port[;...]'
 [USING PARAMETERS
 [kafka_conf='kafka_configuration_setting'
 [, timeout=timeout_sec]])
```

**broker**

The hostname (or ip address) of a broker in the Kafka cluster

**port**

The port number on which the broker is running.

## kafka\_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

## kafka\_conf\_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as [kafka\\_conf](#).

Values passed to this parameter are not logged or stored in system tables.

## timeout

Integer number of seconds to wait for a response from the Kafka cluster.

### Example

```
=> \x
Expanded display is on.
=> SELECT KafkaListManyTopics('kafka01.example.com:9092')
 OVER (PARTITION AUTO);
-[RECORD 1]--+-----
brokers | kafka01.example.com:9092,kafka02.example.com:9092
topic | __consumer_offsets
num_partitions | 50
-[RECORD 2]--+-----
brokers | kafka01.example.com:9092,kafka02.example.com:9092
topic | iot_data
num_partitions | 1
-[RECORD 3]--+-----
brokers | kafka01.example.com:9092,kafka02.example.com:9092
topic | test
num_partitions | 1
```

## KafkaListTopics

Gets the list of topics available from a Kafka broker.

### Syntax

```
KafkaListTopics(USING PARAMETERS brokers='hostname:port[,hostname2:port2...]'
 [, kafka_conf='kafka_configuration_setting']
 [, timeout=timeout_sec])
```

### brokers

The host name and port number of the broker to query for a topic list. You can supply more than one broker as a comma-separated list. However, the returned list will only contains the topics served by the last broker in the list.

### kafka\_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

### kafka\_conf\_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as [kafka\\_conf](#).

Values passed to this parameter are not logged or stored in system tables.

### timeout

Integer number of seconds to wait for a response from the Kafka cluster.

### Example

```
=> SELECT KafkaListTopics(USING PARAMETERS brokers='kafka1-01.example.com:9092')
 OVER ();
 topic | num_partitions
-----+-----
test | 1
iot_data | 1
__consumer_offsets | 50
vertica_notifications | 1
web_hits | 1
(5 rows)
```

## KafkaOffsets

The `KafkaOffsets` user-defined transform function returns load operation statistics generated by the most recent invocation of `KafkaSource`. Query `KafkaOffsets` to see the metadata produced by your most recent load operation. You can query `KafkaOffsets` after each `KafkaSource` invocation to view information about that load. If you are using the scheduler, you can also view historical load information in the [stream\\_microbatch\\_history](#) table.

For each load operation, `KafkaOffsets` returns the following:

- source kafka topic
- source kafka partition
- starting offset
- ending offset
- number of messages loaded
- number of bytes read
- duration of the load operation
- end message
- end reason

The following example demonstrates calling `KafkaOffsets` to show partition information that was loaded using `KafkaSource`:

```
=> SELECT kpartition, start_offset, end_offset, msg_count, ending FROM (select KafkaOffsets() over()) AS stats ORDER BY kpartition;
kpartition | start_offset | end_offset | msg_count | ending
-----+-----+-----+-----+-----
0 | -2 | 9999 | 1068 | END_OFFSET
```

The output shows that `KafkaSource` loaded 1068 messages (rows) from Kafka in a single partition. The `KafkaSource` ended the data load because it reached the ending offset.

### Note

The values shown in the `start_offset` column are exclusive (the message with the shown offset was not loaded) and the values in the `end_offset` column are inclusive (the message with the shown offset was loaded). This is the opposite of the values specified in the `KafkaSource`'s `stream` parameter. The difference between the inclusiveness of `KafkaSource`'s and `KafkaOffset`'s start and end offsets are based on the needs of the job scheduler. `KafkaOffset` is primarily intended for the job scheduler's use, so the start and end offset values are defined so the scheduler can easily start streaming from where left off.

## KafkaParser

The `KafkaParser` does not parse data loaded from Kafka. Instead, it passes the messages through as `LONG VARCHAR` values. Use this parser when you want to load raw Kafka messages into Vertica for further processing. You can use this parser as a catch-all for unsupported formats.

`KafkaParser` does not take any parameters.

### Example

The following example loads raw messages from a Kafka topic named `iot-data` into a table named `raw_iot`.

```

=> CREATE TABLE raw_iot(message LONG VARCHAR);
CREATE TABLE
=> COPY raw_iot SOURCE KafkaSource(stream='iot-data|0|-2,iot-data|1|-2,iot-data|2|-2',
 brokers='docd01:6667,docd03:6667', stop_on_eof=TRUE)
 PARSER KafkaParser();
Rows Loaded

 5000
(1 row)

=> select * from raw_iot limit 10;
 message

10039, 59, -68.951406, -19.270126
10042, 40, -82.688712, 4.7187705
10054, 6, -153.805268, -10.5173935
10054, 71, -135.613150, 58.286458
10081, 44, 130.288419, -77.344405
10104, -5, 77.882598, -56.600744
10132, 87, 103.530616, -69.672863
10135, 6, -121.420382, 15.3229855
10166, 77, -179.592211, 42.0477075
10183, 62, 17.225394, -55.6644765
(10 rows)

```

## KafkaSource

The KafkaSource UDL accesses data from a Kafka cluster. All Kafka parsers must use KafkaSource. Messages processed by KafkaSource must be at least one byte in length. KafkaSource writes an error message to vertica.log for zero-length messages.

The output of KafkaSource does not work directly with any of the non-Kafka parsers in Vertica (such as the FCSVPARSER). The KafkaParser produces additional metadata about the stream that parsers need to use in order to correctly parse the data. You must use filters such as KafkaInsertDelimiters to transform the data into a format that can be processed by other parsers. See [Parsing custom formats](#) for more an example.

You can cancel a running KafkaSource data load by using a close session function such as [CLOSE\\_ALL\\_SESSIONS](#).

## Syntax

```
KafkaSource(stream='topic_name|partition|start_offset|[end_offset]', param=value [...])
```

### stream

Required. Defines the data to be loaded as a comma-separated list of one or more partitions. Each partition is defined by three required values and one optional value separated by pipe characters (|):

- **topic\_name**: the name of the Kafka topic to load data from. You can read from different Kafka topics in the same stream parameter, with some limitations. See [Loading from Multiple Topics in the Same Stream Parameter](#) below for more information.
- **partition**: the partition in the Kafka topic to copy.
- **start\_offset**: the offset in the Kafka topic where the load will begin. This offset is inclusive (the message with the offset **start\_offset** is loaded). See [Special Starting Offset Values](#) below for additional options.
- **end\_offset**: the optional offset where the load should end. This offset is exclusive (the message with the offset **end\_offset** will not be loaded).

To end a load using **end\_offset**, you must supply an ending offset value for all partitions in the stream parameter. Attempting to set an ending offset for some partitions and not set offset values for others results in an error.

If you do not specify an ending offset, you must supply at least one other ending condition using **stop\_on\_eof** or **duration**.

### brokers

A comma-separated list of host:port pairs of the brokers in the Kafka cluster. Vertica recommends running Kafka on a different machine than Vertica.

**Default:** localhost:9092

### duration

AN INTERVAL that specifies the duration of the frame. After this specified amount of time, KafkaSource terminates the COPY statements. If this parameter is not set, you must set at least one other ending condition by using stop\_on\_eof or specify an ending offset instead. See [Duration Note](#) below for more information.

## executionparallelism

The number of threads to use when loading data. Normally, you set this to an integer value between 1 and the number of partitions the node is loading from. Setting this parameter to a reduced value limits the number of threads used to process any COPY statement. It also increases the throughput of short queries issued in the pool, especially if the queries are executed concurrently.

If you do not specify this parameter, Vertica automatically creates a thread for every partition, up to the limit allowed by the resource pool. If the value you specify for the KafkaSource is lower than the value specified for the scheduler resource pool, the KafkaSource value applies. This value cannot exceed the value specified for the scheduler's resource pool.

## stop\_on\_eof

Determines whether KafkaSource should terminate the COPY statement after it reaches the end of a file. If this value is not set, you must set at least one other ending condition using [duration](#) or by supplying ending offsets instead.

**Default:** FALSE

## group\_id

The name of the Kafka consumer group to which Vertica reports its progress consuming messages. Set this value to disable progress reports to a Kafka consumer group. For details, see [Monitoring Vertica message consumption with consumer groups](#).

**Default:** `vertica_ database-name`

## kafka\_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets global configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

## kafka\_topic\_conf

A JSON string of property/value pairs to pass directly to the rdkafka, the library that Vertica uses to communicate with Kafka. This parameter directly sets topic-level configuration properties that are not available through the Vertica integration with Kafka.

For details, see [Directly setting Kafka library options](#).

## kafka\_conf\_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as [kafka\\_conf](#).

Values passed to this parameter are not logged or stored in system tables.

## fail\_on\_conf\_parse\_error

Determines whether the function fails when [kafka\\_conf](#) contains incorrectly formatted options and values, or invalid configuration properties.

**Default Value :** FALSE

For accepted option and value formats, see [Directly setting Kafka library options](#).

For a list of valid configuration properties, see the [rdkafka GitHub repository](#).

## Special starting offset values

The [start\\_offset](#) portion of the [stream](#) parameter lets you start loading messages from a specific point in the topic's partition. It also accepts one of two special offset values:

- -2 tells KafkaSource to start loading at the earliest available message in the topic's partition. This value is useful when you want to load as many messages as you can from the Kafka topic's partition.
- -3 tells KafkaSource to start loading from the consumer group's saved offset. If the consumer group does not have a saved offset, it starts loading from the earliest available message in the topic partition. See [Monitoring Vertica message consumption with consumer groups](#) for more information.

## Loading from multiple topics in the same stream parameter

You can load from multiple Kafka topics in a single stream parameter as long as you follow these guidelines:

- The data for the topics must be in the same format because you pass the data from KafkaSource to a single parser. For example, you cannot load data from one topic that is in Avro format and another in JSON format.
- Similarly, you need to be careful if you are loading Avro data and specifying an external schema from a registry. The Avro parser accepts a single schema per data load. If the data from the separate topics have different schemas, then all of the data from one of the topics will be rejected.

- The data in the different topics should have the same (or very similar) schemas, especially if you are loading data into a traditional Vertica table. While you can load data with different schemas into a flex table, there are only a few scenarios where it makes sense to combine dissimilar data into a single table.

#### Duration note

The `duration` parameter applies to the length of time that Vertica allows the `KafkaSource` function to run. It usually reflects the amount of time the overall load statement takes. However, if `KafkaSource` is loading a large volume of data or the data needs extensive processing and parsing, the overall runtime of the query can exceed the amount of time specified in `duration`.

#### Example

The following example demonstrates calling `KafkaSource` to load data from Kafka into an existing flex table named `web_table` with the following options:

- The stream is named `web_hits` which has a single partition.
- The load starts at the earliest message in the stream (identified by passing `-2` as the start offset).
- The load ends when it reaches the message with offset 1000.
- The Kafka cluster's brokers are `kafka01` and `kafka03` in the `example.com` domain.
- The brokers are listening on port 9092.
- The load ends if it reaches the end of the stream before reaching the message with offset 1000. If you do not supply this option, the connector waits until Kafka sends a message with offset 1000.
- The loaded data is sent to the `KafkaJSONParser` for processing.

```
=> COPY web_table
SOURCE KafkaSource(stream='web_hits|0|-2|1000',
 brokers='kafka01.example.com:9092,kafka03.example.com:9092',
 stop_on_eof=true)
PARSER KafkaJSONParser();
Rows Loaded

 1000
(1 row)
```

To view details about this load operation, query [KafkaOffsets](#). `KafkaOffsets` returns metadata about the messages that Vertica consumed from Kafka during the most recent `KafkaSource` invocation:

```
=> SELECT KafkaOffsets() OVER();
 ktopic | kpartition | start_offset | end_offset | msg_count | bytes_read | duration | ending | end_msg
-----+-----+-----+-----+-----+-----+-----+-----+-----
web_hits | 0 | 0 | 999 | 1000 | 197027 | 00:00:00.385365 | END_OFFSET | Last message read
(1 row)
```

The `msg_count` column verifies that Vertica loaded 1000 messages, and the `ending` column indicates that Vertica stopped consuming messages when it reached the message with the offset 1000.

#### KafkaTopicDetails

Retrieves information about the specified topic from one or more Kafka brokers. This function lists details about the topic partitions, and the Kafka brokers that serve each partition in the Kafka cluster.

#### Syntax

```
KafkaTopicDetails(USING PARAMETERS brokers='hostname:port[,hostname2:port2...]'
 , topic=topic_name
 [, kafka_conf='option=value[:option2=value2...]'
 [, timeout=timeout_sec])
```

#### **brokers**

The hostname (or IP address) of a broker in the Kafka cluster.

#### **port**

The port number on which the broker is running.

#### **topic**

Kafka topic that you want details for.

#### **kafka\_conf**

A semicolon-delimited list of *option = value* pairs to pass directly to the rdkafka library. This is the library Vertica uses to communicate with Kafka. You can use this parameter to directly set configuration options that are not available through the Vertica integration with Kafka. See [Directly setting Kafka library options](#) for details.

### kafka\_conf\_secret

Conceals sensitive configuration data that you must pass directly to the rdkafka library, such as passwords. This parameter accepts settings in the same format as `kafka_conf`.

Values passed to this parameter are not logged or stored in system tables.

### timeout

Integer number of seconds to wait for a response from the Kafka cluster.

### Example

```
=> SELECT KafkaTopicDetails(USING PARAMETERS brokers='kafka1-01.example.com:9092',topic='iot_data') OVER();
partition_id | lead_broker | replica_brokers | in_sync_replica_brokers
-----+-----+-----+-----
0 | 0 | 0 | 0
1 | 1 | 1 | 1
2 | 0 | 0 | 0
3 | 1 | 1 | 1
4 | 0 | 0 | 0
(5 rows)
```

## Data streaming schema tables

Every time you create a scheduler ( `--create` ), Vertica creates a schema for that scheduler with the name you specify or the default `stream_config`. Each schema has the following tables:

- [stream\\_clusters](#)
- [stream\\_events](#)
- [stream\\_load\\_specs](#)
- [stream\\_microbatch\\_history](#)
- [stream\\_microbatch\\_source\\_map](#)
- [stream\\_microbatches](#)
- [stream\\_scheduler](#)
- [stream\\_scheduler\\_history](#)
- [stream\\_sources](#)
- [stream\\_targets](#)

### Caution

Vertica recommends that you do not alter these tables except in consultation with support.

### stream\_clusters

This table lists clusters and hosts. You change settings in this table using the vkconfig cluster tool. See [Cluster tool options](#) for more information.

Column	Data Type	Description
id	INTEGER	The identification number assigned to the cluster.
cluster	VARCHAR	The name of the cluster.
hosts	VARCHAR	A comma-separated list of hosts associated with the cluster.

### Examples

This example shows a cluster and its associated hosts.

```
=> SELECT * FROM stream_config.stream_clusters;
```

```
id | cluster | hosts
-----+-----+-----
2250001 | streamcluster1 | 10.10.10.10:9092,10.10.10.11:9092
(1 rows)
```

## stream\_events

This table logs microbatches and other important events from the scheduler in an internal log table.

This table was renamed from kafka\_config.kafka\_events.

Column	Data Type	Description
event_time	TIMESTAMP	The time the event was logged.
log_level	VARCHAR	The type of event that was logged.  <b>Valid Values:</b> <ul style="list-style-type: none"><li>• TRACE</li><li>• DEBUG</li><li>• FATAL</li><li>• ERROR</li><li>• WARN</li><li>• INFO</li></ul> <b>Default:</b> INFO
frame_start	TIMESTAMP	The time when the frame executed.
frame_end	TIMESTAMP	The time when the frame completed.
microbatch	INTEGER	The identification number of the associated microbatch.
message	VARCHAR	A description of the event.
exception	VARCHAR	If this log is in the form of a stack trace, this column lists the exception.

## Examples

This example shows typical rows from the stream\_events table.

```

=> SELECT * FROM stream_config.stream_events;
-[RECORD 1]-+-----
event_time | 2016-07-17 13:28:35.548-04
log_level | INFO
frame_start |
frame_end |
microbatch |
message | New leader registered for schema stream_config. New ID: 0, new Host: 10.20.30.40
exception |
-[RECORD 2]-+-----
event_time | 2016-07-17 13:28:45.643-04
log_level | INFO
frame_start | 2015-07-17 12:28:45.633
frame_end | 2015-07-17 13:28:50.701-04
microbatch |
message | Generated tuples: test3|2|-2,test3|1|-2,test3|0|-2
exception |
-[RECORD 3]-+-----
event_time | 2016-07-17 14:28:50.701-04
log_level | INFO
frame_start | 2016-07-17 13:28:45.633
frame_end | 2016-07-17 14:28:50.701-04
microbatch |
message | Total rows inserted: 0
exception |

```

## stream\_load\_specs

This table describes user-created load specs. You change the entries in this table using the vkconfig utility's [load\\_spec tool](#).

Column	Data Type	Description
id	INTEGER	The identification number assigned to the cluster.
load_spec	VARCHAR	The name of the load spec.
filters	VARCHAR	A comma-separated list of UDFilters for the scheduler to include in the COPY statement it uses to load data from Kafka.
parser	VARCHAR	A Vertica UDFParser to use with a specified target. If you are using a Vertica native parser, parser parameters serve as a COPY statement parameters.
parser_parameters	VARCHAR	A list of parameters to provide to the parser.
load_method	VARCHAR	The COPY load method to use for all loads with this scheduler. <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>Deprecated</b> In Vertica 10.0, load methods are no longer used due to the removal of the WOS. The value shown in this column has no effect.</p> </div>
message_max_bytes	INTEGER	The maximum size, in bytes, of a message.
uds_kv_parameters	VARCHAR	A list of parameters that are supplied to the KafkaSource statement. If the value in this column is in the format <i>key = value</i> , the scheduler it to the COPY statement's KafkaSource call.

## Examples

This example shows the load specs that you can use with a Vertica instance.

```
SELECT * FROM stream_config.stream_load_specs;
-[RECORD 1]-----+-----
id | 1
load_spec | loadspec2
filters |
parser | KafkaParser
parser_parameters |
load_method | direct
message_max_bytes | 1048576
uds_kv_parameters |
-[RECORD 2]-----+-----
id | 750001
load_spec | streamspec1
filters |
parser | KafkaParser
parser_parameters |
load_method | TRICKLE
message_max_bytes | 1048576
uds_kv_parameters |
```

### stream\_lock

This table is locked by the scheduler. This locks prevent multiple schedulers from running at the same time. The scheduler that locks this table updates it with its own information.

#### Important

Do not use this table in a serializable transaction that locks this table. Locking this table can interfere with the operation of the scheduler.

Column	Data Type	Description
scheduler_id	INTEGER	A unique ID for the scheduler instance that is currently running.
update_time	TIMESTAMP	The time the scheduler took ownership of writing to the schema.
process_info	VARCHAR	Information about the scheduler process. Currently unused.

#### Example

```
=> SELECT * FROM weblog_sched.stream_lock;
scheduler_id | update_time | process_info
-----+-----
2 | 2018-11-08 10:12:36.033 |
(1 row)
```

### stream\_microbatch\_history

This table contains a history of every microbatch executed within this scheduler configuration.

Column	Data Type	Description
source_name	VARCHAR	The name of the source.
source_cluster	VARCHAR	The name of the source cluster. The clusters are defined in <a href="#">stream_clusters</a> .
source_partition	INTEGER	The number of the data streaming partition.
start_offset	INTEGER	The starting offset of the microbatch.

end_offset	INTEGER	The ending offset of the microbatch.
end_reason	VARCHAR	An explanation for why the batch ended. The following are valid end reasons: <ul style="list-style-type: none"> <li>• DEADLINE - The batch ran out of time.</li> <li>• END_OFFSET - The load reached the ending offset specified in the KafkaSource. This reason is never used by the scheduler, as it does not specify an end offset.</li> <li>• END_OF_STREAM - There are no messages available to the scheduler or the eof_timeout has been reached.</li> <li>• NETWORK_ERROR - The scheduler could not connect to Kafka.</li> <li>• RESET_OFFSET - The start offset was changed using the <code>--update</code> and <code>--offset</code> parameters to the KafkaSource. This state does not occur during normal scheduler operations.</li> <li>• SOURCE_ISSUE - The Kafka service returned an error.</li> <li>• UNKNOWN - The batch ended for an unknown reason.</li> </ul>
end_reason_message	VARCHAR	If the end reason is a network or source issue, this column contains a brief description of the issue.
partition_bytes	INTEGER	The number of bytes transferred from a source partition to a Vertica target table.
partition_messages	INTEGER	The number of messages transferred from a source partition to a Vertica target table.
microbatch_id	INTEGER	The Vertica transaction id for the batch session.
microbatch	VARCHAR	The name of the microbatch.
target_schema	VARCHAR	The name of the target schema.
target_table	VARCHAR	The name of the target table.
timeslice	INTERVAL	The amount of time spent in the KafkaSource operator.
batch_start	TIMESTAMP	The time the batch executed.
batch_end	TIMESTAMP	The time the batch completed.
last_batch_duration	INTERVAL	The length of time required to run the complete COPY statement.
last_batch_parallelism	INTEGER	The number of parallel COPY statements generated to process the microbatch during the last frame.
microbatch_sub_id	INTEGER	The identifier for the COPY statement that processed the microbatch.
consecutive_error_count	INTEGER	(Currently not used.) The number of times a microbatch has encountered an error on an attempt to load. This value increases over multiple attempts.
transaction_id	INTEGER	The identifier for the transaction within the session.
frame_start	TIMESTAMP	The time the frame started. A frame can contain multiple microbatches.
frame_end	TIMESTAMP	The time the frame completed.

## Examples

This example shows typical rows from the `stream_microbatch_history` table.

```
=> SELECT * FROM stream_config.stream_microbatch_history;
```

```
-[RECORD 1]--+-+-----
source_name | streamsource1
source_cluster | kafka-1
source_partition | 0
start_offset | 196
end_offset | 196
end_reason | END_OF_STREAM
partition_bytes | 0
partition_messages | 0
microbatch_id | 1
microbatch | mb_0
target_schema | public
target_table | kafka_flex_0
timeslice | 00:00:09.892
batch_start | 2016-07-28 11:31:25.854221
batch_end | 2016-07-28 11:31:26.357942
last_batch_duration | 00:00:00.379826
last_batch_parallelism | 1
microbatch_sub_id | 0
consecutive_error_count |
transaction_id | 45035996275130064
frame_start | 2016-07-28 11:31:25.751
frame_end |
end_reason_message |
```

```
-[RECORD 2]--+-+-----
source_name | streamsource1
source_cluster | kafka-1
source_partition | 1
start_offset | 197
end_offset | 197
end_reason | NETWORK_ISSUE
partition_bytes | 0
partition_messages | 0
microbatch_id | 1
microbatch | mb_0
target_schema | public
target_table | kafka_flex_0
timeslice | 00:00:09.897
batch_start | 2016-07-28 11:31:45.84898
batch_end | 2016-07-28 11:31:46.253367
last_batch_duration | 000:00:00.377796
last_batch_parallelism | 1
microbatch_sub_id | 0
consecutive_error_count |
transaction_id | 45035996275130109
frame_start | 2016-07-28 11:31:45.751
frame_end |
end_reason_message | Local: All brokers are down
```

#### stream\_microbatch\_source\_map

This table maps microbatches to the their associated sources.

Column	Data Type	Description
microbatch	INTEGER	The identification number of the microbatch.

source	INTEGER	The identification number of the associated source.
--------	---------	-----------------------------------------------------

#### Examples

This example shows typical rows from the stream\_microbatch table.

```
SELECT * FROM stream_config.stream_microbatch_source_map;
```

```
microbatch | source
```

```
-----+-----
```

```
1 | 4
```

```
3 | 2
```

```
(2 rows)
```

#### stream\_microbatches

This table contains configuration data related to microbatches.

Column	Data Type	Description
id	INTEGER	The identification number of the microbatch.
microbatch	VARCHAR	The name of the microbatch.
target	INTEGER	The identification number of the target associated with the microbatch.
load_spec	INTEGER	The identification number of the load spec associated with the microbatch.
target_columns	VARCHAR	The table columns associated with the microbatch.
rejection_schema	VARCHAR	The schema that contains the rejection table.
rejection_table	VARCHAR	The table where Vertica stores messages that are rejected by the database.
max_parallelism	INTEGER	The number of parallel COPY statements the scheduler uses to process the microbatch.
enabled	BOOLEAN	When TRUE, the microbatch is enabled for use.
consumer_group_id	VARCHAR	The name of the Kafka consumer group to report loading progress to. This value is NULL if the microbatch reports its progress to the default consumer group for the scheduler. See <a href="#">Monitoring Vertica message consumption with consumer groups</a> for more information.

#### Examples

This example shows a row from a typical stream\_microbatches table.

```

=> select * from weblog_sched.stream_microbatches;
-[RECORD 1]-----+-----
id | 750001
microbatch | weberrors
target | 750001
load_spec | 2250001
target_columns |
rejection_schema |
rejection_table |
max_parallelism | 1
enabled | t
consumer_group_id |
-[RECORD 2]-----+-----
id | 1
microbatch | weblog
target | 1
load_spec | 1
target_columns |
rejection_schema |
rejection_table |
max_parallelism | 1
enabled | t
consumer_group_id | weblog_group

```

## stream\_scheduler

This table contains metadata related to a single scheduler.

This table was renamed from `kafka_config.kafka_scheduler`. This table used to contain a column named `eof_timeout_ms`. It has been removed.

Column	Data Type	Description
version	VARCHAR	The version of the scheduler.
frame_duration	INTERVAL	The length of time of the frame. The default is 00:00:10.
resource_pool	VARCHAR	The resource pool associated with this scheduler.
config_refresh	INTERVAL	The interval of time that the scheduler runs before applying any changes to its metadata, such as, changes made using the <code>--update</code> option.  For more information, refer to <code>--config-refresh</code> in <a href="#">Scheduler tool options</a> .
new_source_policy	VARCHAR	When during the frame that the source runs. Set this value with the <code>--new-source-policy</code> in <a href="#">Source tool options</a> .  <b>Valid Values:</b> <ul style="list-style-type: none"> <li>FAIR: Takes the average length of time from the previous batches and schedules itself appropriately.</li> <li>START: Runs all new sources at the beginning of the frame. In this case, Vertica gives the minimal amount of time to run.</li> <li>END: Runs all new sources starting at the end of the frame. In this case, Vertica gives the maximum amount of time to run.</li> </ul> <b>Default:</b>  FAIR

pushback_policy	VARCHAR	(Not currently used.) How Vertica handles delays for microbatches that continually fail.  <b>Valid Values:</b>  <ul style="list-style-type: none"> <li>• FLAT</li> <li>• LINEAR</li> <li>• EXPONENTIAL</li> </ul> <b>Default:</b>  LINEAR
pushback_max_count	INTEGER	(Currently not used.) The maximum number of times a microbatch can fail before Vertica terminates it.
auto_sync	BOOLEAN	When TRUE, the scheduler automatically synchronizes source information with host clusters. For more information, refer to <a href="#">Automatically consume data from Kafka with a scheduler</a> .  <b>Default:</b>  TRUE
consumer_group_id	VARCHAR	The name of the Kafka consumer group to which the scheduler reports its progress in consuming messages. This value is NULL if the scheduler reports to the default consumer group named <code>vertica-<i>database_name</i></code> . See <a href="#">Monitoring Vertica message consumption with consumer groups</a> for more information.

#### Examples

This example shows a typical row in the `stream_scheduler` table.

```
=> SELECT * FROM weblog_sched.stream_scheduler;
-[RECORD 1]-----+-----
version | v9.2.1
frame_duration | 00:05:00
resource_pool | weblog_pool
config_refresh | 00:05
new_source_policy | FAIR
pushback_policy | LINEAR
pushback_max_count | 5
auto_sync | t
consumer_group_id | vertica-consumer-group
```

#### stream\_scheduler\_history

This table shows the history of launched scheduler instances.

This table was renamed from `kafka_config.kafka_scheduler_history`.

Column	Data Type	Description
elected_leader_time	TIMESTAMP	The time when this instance took began scheduling operations.
host	VARCHAR	The host name of the machine running the scheduler instance.
launcher	VARCHAR	The name of the currently active scheduler instance.  <b>Default:</b> NULL
scheduler_id	INTEGER	The identification number of the scheduler.
version	VARCHAR	The version of the scheduler.

#### Examples

This example shows typical rows from the stream\_scheduler\_history table.

```
SELECT * FROM stream_config.stream_scheduler_history;
 elected_leader_time | host | launcher | scheduler_id | version
-----+-----+-----+-----+-----
2016-07-26 13:19:42.692 | 10.20.100.62 | | 0 | v8.0.0
2016-07-26 13:54:37.715 | 10.20.100.62 | | 1 | v8.0.0
2016-07-26 13:56:06.785 | 10.20.100.62 | | 2 | v8.0.0
2016-07-26 13:56:56.033 | 10.20.100.62 | SchedulerInstance | 3 | v8.0.0
2016-07-26 15:51:20.513 | 10.20.100.62 | SchedulerInstance | 4 | v8.0.0
2016-07-26 15:51:35.111 | 10.20.100.62 | SchedulerInstance | 5 | v8.0.0
(6 rows)
```

### stream\_sources

This table contains metadata related to data streaming sources.

This table was formerly named kafka\_config.kafka\_scheduler.

Column	Data Type	Description
id	INTEGER	The identification number of the source
source	VARCHAR	The name of the source.
cluster	INTEGER	The identification number of the cluster associated with the source.
partitions	INTEGER	The number of partitions in the source.
enabled	BOOLEAN	When TRUE, the source is enabled for use.

### Examples

This example shows a typical row from the stream\_sources table.

```
select * from stream_config.stream_sources;
-[RECORD 1]-----
 id | 1
 source | SourceFeed1
 cluster | 1
 partitions | 1
 enabled | t
-[RECORD 2]-----
 id | 250001
 source | SourceFeed2
 cluster | 1
 partitions | 1
 enabled | t
```

### stream\_targets

This table contains the metadata for all Vertica target tables.

The table was formerly named kafka\_config.kafka\_targets.

Column	Data Type	Description
id	INTEGER	The identification number of the target table
target_schema	VARCHAR	The name of the schema for the target table.
target_table	VARCHAR	The name of the target table.

## Examples

This example shows typical rows from the stream\_tables table.

```
=> SELECT * FROM stream_config.stream_targets;
-[RECORD 1]-----+-----
id | 1
target_schema | public
target_table | stream_flex1
-[RECORD 2]-----+-----
id | 2
target_schema | public
target_table | stream_flex2
```

## Apache Spark integration

Apache Spark is an open-source, general-purpose cluster-computing framework. See the [Apache Spark website](#) for more information. Vertica provides a Spark connector that you install into Spark that lets you transfer data between Vertica and Spark.

Using the connector, you can:

- Copy large volumes of data from Spark DataFrames to Vertica tables. This feature lets you save your Spark analytics in Vertica.
- Copy data from Vertica to Spark RDDs or DataFrames for use with Python, R, Scala and Java. The connector efficiently pushes down column selection and predicate filtering to Vertica before loading the data.

The connector lets you use Spark to preprocess data for Vertica and to use Vertica data in your Spark application. You can even round-trip data from Vertica to Spark—copy data from Vertica to Spark for analysis, and then save the results of that analysis back to Vertica.

See the [spark-connector project](#) on GitHub for more information about the connector.

## How the connector works

The Spark connector is a library that you incorporate into your Spark applications to read data from and write data to Vertica. When transferring data, the connector uses an intermediate storage location as a buffer between the Vertica and Spark clusters. Using the intermediate storage location lets both Vertica and Spark use all of the nodes in their clusters to transfer data in parallel.

When transferring data from Vertica to Spark, the connector tells Vertica to write the data as Parquet files in the intermediate storage location. As part of this process, the connector pushes down the required columns and any Spark data filters into Vertica as SQL. This push down lets Vertica pre-filter the data so it only copies the data that Spark needs. Once Vertica finishes copying the data, the connector has Spark load it into DataFrames from the intermediate location.

When transferring data from Spark to Vertica, the process is reversed. Spark writes data into the intermediate storage location. It then connects to Vertica and runs a COPY statement to load the data from the intermediate location into a table.

## Getting the connector

The Spark connector is an open source project. For the latest information on it, visit the [spark-connector project](#) on GitHub. To get an alert when there are updates to the connector, you can log into a GitHub account and click the **Notifications** button on any of the project's pages.

You have three options to get the Spark connector:

- Get the connector from [Maven Central](#). If you use Gradle, Maven, or SBT to manage your Spark applications, you can add a dependency to your project to automatically get the connector and its dependencies and add them into your Spark application. See [Getting the Connector from Maven Central](#) below.
- Download a precompiled assembly from the GitHub project's [releases page](#). Once you have downloaded the connector, you must configure Spark to use it. See [Deploy the Connector to the Spark Cluster](#) below.
- Clone the connector project and compile it. This option is useful if you want features or bugfixes that have not been released yet. See [Compiling the Connector](#) below.

See the [Spark connector project](#) on GitHub for detailed instructions on deploying and using the connector.

### Getting the connector from maven central

The Vertica Spark connector is available from the Maven Central Repository. Using Maven Central is the easiest method of getting the connector if your build tool supports downloading dependencies from it.

If your Spark project is managed by Gradle, Maven, or SBT you can add the Spark connector to it by listing it as a dependency in its configuration file. You may also have to enable Maven Central if your build tool does not automatically do so.

For example, suppose you use SBT to manage your Spark application. In this case, the Maven Central repository is enabled by default. All you need to do is add the `com.vertica.spark` dependency to your `build.sbt` file.

See the [com.vertica.spark](#) page on the Maven Repository site for more information on the available Spark connector versions and dependency information for your build system.

## Compiling the connector

You may choose to compile the Spark connector if you want to test new features or bugfixes that have not yet been released. Compiling the connector is necessary if you plan on contributing your own features.

To compile the connector, you need:

- The SBT build tool. In order to compile the connector, you must install SBT and all of its dependencies (including a version of the Java SDK). See the [SBT documentation](#) for requirements and installation instructions.
- [git](#) to clone the Spark connector V2 source from the GitHub.

As a quick overview, executing the following commands on a Linux command line will download the source and compile it into an assembly file:

```
$ git clone https://github.com/vertica/spark-connector.git
$ cd spark-connector/connector
$ sbt assembly
```

Once compiled, the connector is located at `target/scala-n.n/spark-vertica-connector-assembly-x.x.jar`. The *n.n* is the currently-supported version of Scala and *x.x* is the current version of the Spark connector.

See the [CONTRIBUTING](#) document in the connector's GitHub project for detailed requirements and compiling instructions.

Once you compile the connector, you must deploy it to your Spark cluster. See the next section for details.

## Deploy the connector to the Spark cluster

If you downloaded the Spark connector from GitHub or compiled it yourself, you must deploy it to your Spark cluster before you can use it. Two options include copying it to a Spark node and including it in a `spark-submit` or `spark-shell` command or deploying it to the entire cluster and having it loaded automatically.

### Loading the Spark connector from the command line

The quickest way to use the connector is to include it in the `--jars` argument when executing a `spark-submit` or `spark-shell` command. To be able to use the connector in the command line, you must first copy its assembly JAR to the Spark node on which you will run the commands. Then add the path to the assembly JAR file as part of the `--jars` command line argument.

For example, suppose you copied the assembly file to your current directory on a Spark node. Then you could load the connector when starting `spark-shell` with the command:

```
spark-shell --jars spark-vertica-connector-assembly-x.x.jar
```

You could also enable the connector when submitting a Spark job using `spark-submit` with the command:

```
spark-submit --jars spark-vertica-connector-assembly-x.x.jar
```

### Configure Spark to automatically load the connector

You can configure your Spark cluster to automatically load the connector. Deploying the connector this way ensures that the Spark connector is available to all Spark applications on your cluster.

To have Spark automatically load the Spark connector:

1. Copy the Spark connector's assembly JAR file to the same path on all of the nodes in your Spark cluster. For example, on Linux you could copy the `spark-vertica-connector-assembly-x.x.jar` file to the `/usr/local/lib` directory on every Spark node. The file must be in the same location on each node.
2. In your Spark installation directories on each node in your cluster, edit the `conf/spark-defaults.conf` file to add or alter the following line:

```
spark.jars /path_to_assembly/spark-vertica-connector-assembly-x.x.jar
```

For example, if you copied the assembly JAR file to `/usr/local/lib`, you would add:

```
spark.jars /usr/local/lib/spark-vertica-connector-assembly-x.x.jar
```

### Note

If the `spark.jars` line already exists in the configuration file, add a comma to the end of the line, then add the path to the assembly file. Do not add a space between the comma and the surrounding values.

If you have the JAR files for the Spark connector V1 in your configuration file, you do not need to remove them. Both connector versions can be loaded into Spark at the same time without a conflict.

3. Test your configuration by starting a Spark shell and entering the statement:

```
import com.vertica.spark._
```

If the statement completes successfully, then Spark was able to locate and load the Spark connector library correctly.

## Prior connector versions

The Vertica Spark connector is an open source project available from GitHub. It is released on a separate schedule than the Vertica server.

Versions of Vertica prior to 11.0.2 distributed a closed-source proprietary version of the Spark connector. This legacy version is no longer supported, and is not distributed with the Vertica server install package.

The newer open source Spark connector differs from the old one in the following ways:

- The new connector uses the Spark V2 API. Using this newer API makes it more future-proof than the legacy connector, which uses an older Spark API.
- The primary class name has changed. Also, the primary class has several renamed configuration options and a few removed options. See [Migrating from the legacy Vertica Spark connector](#) for a list of these changes.
- It supports more features than the older connector, such as Kerberos authentication and S3 intermediate storage.
- It comes compiled as an assembly which contains supporting libraries such as the Vertica JDBC library.
- It is distributed separate from the Vertica server. You can directly download it from the GitHub project. It is also available from the Maven Central Repository, making it easier for you to integrate it into your Gradle, Maven, or SBT workflows.
- It is an open-source project that is not tied to the Vertica server release cycle. New features and bug fixes do not have to wait for a Vertica release. You can also contribute your own features and fixes.

If you have Spark applications that used the previous version of the Spark connector, see [Migrating from the legacy Vertica Spark connector](#) for instructions on how to update your Spark code to work with the new connector.

If you are still using a version of Spark earlier than 3.0, you must use the legacy version of the Spark connector. The new open source version is incompatible with older versions of Spark. You can get the older connector by downloading and extracting a Vertica installation package earlier than version 11.0.2.

In this section

- [Migrating from the legacy Vertica Spark connector](#)

## Migrating from the legacy Vertica Spark connector

If you have existing Spark applications that used the closed-source Vertica Spark connector, you must update them to work with the newer open source connector. The new connector offers new features, better performance, and is under ongoing development. The old connector has been removed from service.

### Deployment changes between the old and connectors

The legacy connector was only distributed with the Vertica server install. The new connector is distributed via several channels giving you more ways to deploy it.

The new Spark connector is available from Maven Central. If you use Gradle, Maven, or SBT to manage your Spark applications, you may find it more convenient to deploy the Spark connector using a dependency rather than manually installing it on your Spark cluster. Integrating the connector into your Spark project as a dependency makes updating to newer versions of the connector easy—just update the required version in the dependency. See [Getting the Connector from Maven Central](#) for more information.

You can also download the precompiled connector assembly or build it from source. In this case, you must deploy the connector to your Spark cluster. The legacy connector depended on the Vertica JDBC driver and required that you separately include it. The new connector is an assembly that incorporates all of its dependencies, including the JDBC driver. You only need to deploy a single JAR file containing the Spark connector to your Spark cluster.

You can have Spark load both the legacy and new connector at the same time because the new connector's primary class name is different (see below). This renaming lets you add the new connector to your Spark configuration files without having to immediately port all of your Spark applications that use the legacy connector to the new API. You can just add the new assembly JAR file to spark-jars list in the [spark-defaults.conf](#) file.

## API changes

There are several API changes from the legacy connector to the new connector require changes to your Spark application.

### VerticaRDD class no longer supported

The legacy connector supported a class named [VerticaRDD](#) to load data from Vertica using the Spark resilient distributed dataset (RDD) feature. The new connector does not support this separate class. Instead, if you want to directly manipulate an RDD, access it through the [DataFrame](#) object you create using the [DataSource](#) API.

### DefaultSource class renamed VerticaSource

The primary class in the legacy connector is named [DataSource](#). In the new connector, this class has been renamed to [VerticaSource](#). This renaming lets both connectors coexist, allowing you to gradually transition your Spark applications.

For your existing Spark application to use the new connector, you must change calls to the [DataSource](#) class to the [VerticaSource](#) class. For example, suppose your Spark application has this method call to read data from the legacy connector:

```
spark.read.format("com.vertica.spark.datasource.DefaultSource").options(opts).load()
```

Then to have it use the new connector, use this method call:

```
spark.read.format("com.vertica.spark.datasource.VerticaSource").options(opts).load()
```

### Changed API options

In addition to renaming of the [DataSource](#) class to [VerticaSource](#), some of the names for options for the primary connector class have changed. Other options are no longer supported. If you are porting a Spark application from the legacy to the new connector that uses one of the following options, you must update your code:

Legacy DataSource Option	New VerticaSource Option	Description
<a href="#">fileformat</a>	none	The new connector does not support the fileformat option. The files that Vertica and Spark write to the intermediate storage location are always in parquet format.
<a href="#">hdfs_url</a>	<a href="#">staging_fs_url</a>	The location of the intermediate storage location that Vertica and Spark use to exchange data. Renamed to be more general, as the new connector supports storage platforms in addition to HDFS.
<a href="#">logging_level</a>	none	The connector no longer supports setting a logging level. Instead, set the logging level in Spark.
<a href="#">numpartitions</a>	<a href="#">num_partitions</a>	The number of Spark partitions to use when reading data from Vertica.
<a href="#">target_table_ddl</a>	<a href="#">target_table_sql</a>	A SQL statement for Vertica to execute before loading data from Spark.
<a href="#">web_hdfs_url</a>	<a href="#">staging_fs_url</a>	Use the same option for a web HDFS URL as you would for an S3 or HDFS storage location.

In addition, the new connector has added options to support new features such as Kerberos authentication. For details on the connector's VerticaSource options API, see the [Vertica Spark connector GitHub project](#).

### Take advantage of new features

The new Vertica Spark connector offers new features that you may want to take advantage of.

Currently, the most notable new features are:

- Kerberos authentication. This feature lets you configure the connector for passwordless connections to Vertica. See the [Kerberos documentation](#) in the Vertica Spark connector GitHub project for details of using this feature.
- Support for using S3 for intermediate storage. This option lets you avoid having to set up a Hadoop cluster solely to host an HDFS storage location. See the [S3 user guide](#) at the connector GitHub site.

# Voltage SecureData integration

Voltage SecureData is a suite of encryption technologies that let you integrate end-to-end data encryption into other applications. It uses Format-Preserving Encryption (FPE): the encrypted values have the same overall format as the unencrypted data. This feature means you do not have to change the data types of table columns that you want to encrypt. It also preserves reference integrity: the encrypted values have the same sort order as unencrypted data, and encrypted values can be cross-referenced between tables, as long as each instance of the value is encrypted with the same key.

See the [Voltage web site](#) for more about SecureData.

This section explains how you can integrate the SecureData encryption feature into Vertica.

In this section

- [How Vertica and SecureData work together](#)
- [Requirements for integrating with SecureData](#)

## How Vertica and SecureData work together

Vertica provides functions to encrypt and decrypt data using SecureData.

Voltage SecureData supplies a number of interfaces for applications to use its encryption: web-based APIs, command-line tools, and SDKs for C, C#, and Java. Vertica has developed a connector that calls the SecureData API that lets you:

- Encrypt sensitive data as it is being loaded into Vertica using SecureData's FPE feature. You can ensure data is stored in Vertica in its encrypted state (referred to as "encrypted at rest"). Authorized users can decrypt the data as needed. Unauthorized users only see the encrypted values. Decryption for authorized users can be automated using views or access policies. The data is transparently decrypted for them.
- Encrypt semi-sensitive data that is stored unencrypted in Vertica so unauthorized users only see a masked version of the data. You can also automate this on-the-fly encryption using access policies.

The encryption method you choose depends on the data you are processing. For example, regulations or contracts may require you to encrypt specific pieces of data. In these cases, use SecureData to encrypt your data as it is loaded, so it is never stored in an unencrypted format within Vertica.

In other cases, you may have semi-sensitive data that you can choose between the two options. In these cases, choose the method that requires the least number of encryptions or decryptions (and therefore of calls to SecureData). If most of the queries on the data need to be masked from users who should not see the unencrypted values, then encrypt the data at rest. Alternatively, if the most of the queries will be from authorized users, with only occasional queries where the data should be masked, then store the data in an unencrypted format and use on-the-fly encryption to mask the data.

## Requirements for integrating with SecureData

Before you can use SecureData with Vertica, you must verify the following:

- You are using version 6.0 or later of SecureData. The Vertica integration functions use APIs introduced in version 6.0 of SecureData.
- All of the nodes in your Vertica cluster are able to communicate with all of your SecureData appliance hosts. Any firewalls between your Vertica cluster and your SecureData appliance must allow connections on the ports that SecureData uses for communications. See "Ensuring Access to SecureData Services" in the *Voltage SecureData Appliance Installation Guide* (downloadable with the SecureData ISO) for a list of the ports reserved by SecureData.
- Your Vertica database is not using [Federal information processing standard](#) (FIPS) mode. FIPS is incompatible with the Voltage SecureData integration. When FIPS mode is active, the SecureData integration library is not installed by default. Do not manually install this library if you are using FIPS.
- You are following the [best practices](#) when using Safe Unicode FPE formats.

## Best practices for safe unicode FPE

Starting with Voltage SecureData Simple API 6.0, you can use Safe Unicode Format Preserving Encryption (FPE) formats to encrypt and decrypt Unicode strings.

When encrypting Unicode with Safe Unicode FPE formats, the plaintext passed into the [VoltageSecureProtect](#) function is first encrypted with an alphabet of all Unicode code points, and then encoded with the Base32K-encoding to produce encrypted text in [Unicode Normalization Form C](#) (NFC). The encrypted text will generally consist of 3-byte Chinese and Japanese characters, as they account for a significant portion of the NFC-stable alphabet. [VoltageSecureAccess](#) reverses this process.

Unlike regular FPE, which handles ASCII strings consisting of single bytes, Safe Unicode FPE handles strings consisting of variable-length code points. This variability introduces an important complication: Safe Unicode FPE formats like `UNICODE_BASE32K` are not length-preserving. The encryption algorithm guarantees that the encrypted text will be larger than the original, and failing to account for this expansion can lead to truncated or otherwise improperly stored encrypted text, making decryption impossible.

Additionally, Unicode allows semantically equivalent characters to be encoded in different ways, which means that unnormalized, semantically equivalent plaintexts can have different forms when encrypted, compromising [referential integrity](#). To prevent this, you should always normalize your plaintext strings into their NFC forms before encryption. For more information on Unicode normalization, see the Unicode Consortium's [Normalization FAQ](#).

The encrypted text is guaranteed to be larger than the plaintext in the following ways:

- 16/15ths longer in character-length (rounded up)
- up to 4-times larger (in bytes)

For a list of predefined formats for Safe Unicode FPE, consult your copy of the Voltage SecureData Simple API documentation.

#### Checklist for safe unicode FPE

Before using Safe Unicode FPE:

- Normalize your plaintext to its NFC form before encryption.
- For fixed-length [data types](#): remove any padding from the plaintext string.
- To store the encrypted text, ensure that the columns storing the encrypted text can handle:
  - strings 16/15ths times longer than your longest plaintext string
  - strings up to 4-times larger (in bytes) than your largest plaintext string

## Verifying the Vertica server's access to the SecureData CA certificate

Before you can use SecureData with Vertica, you must verify that the root certificate authority (CA) and any intermediate certificate authority used to sign the SecureData Appliance's certificate are rehashed and stored in the Vertica server's trust store ( `/opt/vertica/packages/voltagesecure/trustStore/` ). Vertica supplies many standard root certificates in this directory. If your SecureData Appliance uses a certificate signed by a standard CA authority, it is likely already in the trust store.

If your SecureData Appliance is using a certificate signed by your own internal CA authority , you must add this CA Certificate to the Vertica trust store.

If you are unsure whether your CA Certificate is in the Vertica trust store, follow the steps under [Troubleshooting Certificate Problems](#) to test whether the Vertica already has the CA certificate. If you are able to retrieve the client policy XML file from the SecureData Appliance, then your Vertica cluster has the correct CA certificate to access SecureData.

### Adding the CA certificate to Vertica

You must add the CA to Vertica trust store before using the SecureData Integration if you used:

- Your own CA certificate to sign your SecureData Appliance's certificate.
- A third-party CA that is not in the Vertica trust store.

To add the CA certificate to the Vertica trust store, you need:

- The certificate authority (CA) file used to sign the SecureData Appliance's certificate. This file must be in `.pem` format.
- The `openssl` or `c_rehash` utility.
- Access to the dbadmin account on the Vertica nodes. This access is required in order to copy the certificate file to trust store directory in the Vertica installation.

To add the CA file to Vertica:

1. Run either `openssl rehash` or `c_rehash` , specifying the directory containing the CA certificate. This creates a symbolic link `hash .0` :

```
openssl rehash directory_of_certificate
```

```
$ c_rehash directory_of_certificate
```

2. On all nodes, use `cp -L` to copy the certificate to `/opt/vertica/packages/voltagesecure/trustStore/`. If the previous step produced more than one symbolic link, run the following command on all of them:

```
$ cp -L hash_0 /opt/vertica/packages/voltagesecure/trustStore/
```

3. Reinstall the SecureData integration library:

```
$ admintools -t install_package -d database_name -p 'password' --package voltagesecure --force-reinstall
```

When Vertica reinstalls the SecureData integration library, it copies the CA authority file to the all nodes in the cluster. After the file is distributed, all Vertica nodes can authenticate with the SecureData Appliance.

For example, for a database `VMart` and a certificate file `my_ca_cert.pem` :

1. Rehash the certificate:

```
$ openssl rehash my_certs
$ ls -l my_certs
total 4
-rwxrwxrwx 1 dbadmin dbadmin 8 Oct 12 14:35 9da13359.0 -> my_ca_cert.pem
-rw-rw-r-- 1 dbadmin dbadmin 1245 Oct 12 14:16 my_ca_cert.pem
```

2. On all nodes, copy the file certificate to the trust store:

```
$ cp -L 9da13359.0 /opt/vertica/packages/voltagesecure/trustStore/
```

3. Run the following on one node:

```
$ admintools -t install_package -d VMart -p dbadmin_password --package voltagesecure --force-reinstall
installing package voltagesecure...
..Success!
```

## Troubleshooting certificate problems

You can test whether the Vertica trust store has the correct certificate by executing the following statement from the Linux command line:

```
curl --capath /vertica_catalog_directory/Libraries/
$(vsq -A -t -c "SELECT sa1_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib;")\
https://SecureData_appliance_hostname/policy/clientPolicy.xml
```

Where:

- `vertica_catalog_directory` is the absolute path to the Vertica catalog directory. See [Understanding the catalog directory](#) for more information about the catalog directory.
- `SecureData_appliance_hostname` is the host name of your Voltage SecureData Appliance.

For example, suppose you are connected to node0001 of the example VMart database. Also, your Voltage SecureData appliance's host name is `voltage-pp-0000.example.com`. Then you would use the following command to test your certificate installation.

```

$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/
$(vsq -A -t -c "SELECT sa_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';") \
https://voltage-pp-0000.example.com/policy/clientPolicy.xml

<clientPolicy version="2">

<server name="SecureDataAppliance" version="6.4.2.232000" />

<localDomains>example.com</localDomains>

<userWhitelist></userWhitelist>

<defaultDistrict value="0" />

<sendUniversalReader value="1" />

<messageFooterGlobal></messageFooterGlobal>

<parameterAggressiveDistricts>example.com</parameterAggressiveDistricts>

<localPolicyLocked value="0" />

<trustedDistricts></trustedDistricts>

<fallThroughDistrict>example.com</fallThroughDistrict>

. . .

```

The `<clientPolicy>...` output (which is the content of the `clientPolicy.xml` file) indicates that the Vertica node was able to use its CA certificate to connect to the SecureData Appliance.

#### Tip

If you are unsure which Format Preserving Encryption (FPE) formats are defined in your SecureData Appliance, examine the output of the `curl` command. Look for the tags with `formatName` attributes which describe each of the formats.

If the CA certificate you installed on Vertica does not match the certificate installed on the SecureData Appliance, you will see an error similar to the following:

```

$ curl --capath /home/dbadmin/VMart/v_vmart_node0001_catalog/Libraries/$(vsq \
-A -t -c "SELECT sa_storage_id from user_libraries WHERE lib_name = 'VoltageSecureLib';") \
https://voltage-pp-0000.example.com/policy/clientPolicy.xml

curl: (60) Peer certificate cannot be authenticated with known CA certificates
More details here: http://curl.haxx.se/docs/sslcerts.html

```

In this case, verify that you have installed the correct CA certificate in Vertica, and that its file name has a `.pem` extension.

If you see other errors, such as "couldn't connect to host," verify that your firewall configuration allows your Vertica nodes to access your SecureData Appliance.

## Configuring access to SecureData

The Vertica integration functions require several pieces of information in order to connect to and authenticate with SecureData.

### SecureData global configuration settings

The SecureData integration has one required setting and two optional settings that you set globally using the [VoltageSecureConfigureGlobal](#) function. This function saves the settings to a configuration file named `/voltagesecure/conf.global` stored in the Vertica Distributed File System (DFS). This file system is used by Vertica to store data that can be accessed by all nodes. You must use the function to create this file before you use any of the other SecureData integration functions. All users who have access to the SecureData functions are able to access the settings in this file.

The one required setting is the URL of the SecureData policy file. This file provides the SecureData integration library with details of how the SecureData Appliance is configured. The library also uses this URL to determine the address of the SecureData Appliance.

The two optional settings are:

- **allow\_short\_fpe** : When set to True, SecureData ignores the lower length limit for encoding FPE values. Usually, SecureData does not use FPE to encrypt data shorter than a lower limit (usually, 8 bits). See the *SecureData Architecture Guide*'s section on Data Length Restrictions for more information.
- **enable\_file\_cache** : When set to True, Vertica caches the SecureData policy file and encryption keys to disk, rather than just to memory. Defaults to false.

This example sets the policy URL globally to <https://voltage-pp-0000.example.com/policy/clientPolicy.xml> and the network timeout to 200 seconds.

```
=> SELECT VoltageSecureConfigureGlobal(USING PARAMETERS
 policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml',
 NETWORK_TIMEOUT=200)
 OVER ();
```

policy_url	allow_short_fpe	enable_file_cache	network_timeout
https://voltage-pp-0000.example.com/policy/clientPolicy.xml			200

(1 row)

Manually refresh the client policy across the nodes:

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
 PolicyRefresh
```

Successfully refreshed policy on node [v\_sandbox\_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

## Important

The SecureData integration only supports one configuration for the SecureData Appliance at a time.

## SecureData user configuration settings

The remaining SecureData settings define SecureData user information. They are usually specific to each user accessing the integration functions. However, you can have all Vertica users share the same SecureData user configuration. These settings are:

- Your authentication credentials for SecureData. The exact information you need depends on your SecureData Appliance's configuration. There are four potential settings you that you can use:
  - **username** : a username that you use to identify yourself. Your user name is either defined by LDAP (when using LDAP authentication) or by the SecureData appliance when using shared secret authentication.
  - **identity** : the SecureData identity to use. See the *SecureData Administrator Guide* for more information about identities in SecureData. The identity usually takes the form of an email address. When your SecureData Appliance uses LDAP authentication, your LDAP account must have access to this identity.
  - **shared\_secret** : a password set in SecureData.
  - **password** : the LDAP password to use to authenticate with SecureData.

You can supply both a username and identity, depending on the SecureData Appliance's configuration. Your SecureData Appliance can be configured to supply the identity based on your SecureData username.

However, you can only use a shared\_secret or a password. If you set both parameters, the Vertica SecureData functions exit with an error.

You have two options for setting these configuration values: setting them in [user-defined session parameters](#), or saving the values in a configuration file stored in the Vertica distributed file system.

## Setting SecureDate user session parameters

Use the [ALTER SESSION](#) statement to set parameters for the voltagesecurelib library. This library contains all of the SecureData functions. The following example demonstrates configuring the session to access SecureData using shared secret authentication.

```
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib identity='alice@example.com';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib username='alice';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib shared_secret='my_shared_secret';
ALTER SESSION
```

Once set, these parameters only last for the duration of your session.

### Saving parameters in configuration files

You can use the [VoltageSecureConfigure](#) function to save SecureData user parameters to a configuration file in the DFS. You must supply a file name for your configuration file. You can choose to store your SecureData parameters in a user-specific file by supplying just a file name, such as [securedata.conf](#) . Behind the scenes, your configuration file is stored in DFS under a directory named for your username. This directory prevents your configuration file from conflicting with other users' files. You do not use this directory name when accessing your configuration file.

You can also store the configuration parameters in an absolute file named [/voltagesecure/conf](#) . All users who have access to the SecureData integration functions can use this configuration file in their function calls. You can use this file if all of the users accessing the SecureData functions share the same SecureData user settings.

### Important

All users that have access to the VoltageSecureConfigure function can write to the global [/voltagesecure/conf](#) file. Users do not need to be able to write to this file in order to use it in calls to the other SecureData integration functions. You will usually choose to either grant users access to VoltageSecureConfigure in order to save their own configuration files, or you will use the global [/voltagesecure/conf](#) file and not grant users access to VoltageSecureConfigure.

Values in the session parameters override values in configuration files.

You call VoltageSecureConfigure with the parameters you want to save to the configuration file. Values that you do not set in this function call are not set in the configuration file. You must supply those values to the other SecureData integration functions using session parameters.

If you choose to save either the password or shared secret to your configuration file, you do not directly pass them to the VoltageSecureConfigure function. Instead, you set the value in the appropriate session variable, and then set either VoltageSecureConfigure's [store\\_password](#) or [store\\_shared\\_secret](#) parameter to true. When either of these parameters are true, VoltageSecureConfigure reads the value from the session variable and saves it in the configuration file.

### Caution

Under normal circumstances, users are not able to directly read data from files stored in DFS. However, all users who have access to UDX functions that read from the DFS could access these files from within Vertica.

In addition, these files are stored as plain text in every node's file system. Anyone with the proper file system access on the nodes can read the file's contents.

You should take both of these facts into consideration when deciding whether to store sensitive information such as passwords or shared secrets in either the shared or per-user configuration files.

### Example: creating a user-specific configuration file

The following example shows how you can create a user-specific configuration file. This example does not store information such as the password or shared secret, so you must still set session parameters for these values before you can call the other SecureData integration functions.

```
=> \x
Expanded display is on.
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
 username='alice', identity='alice@example.com', store_password=false
) OVER ();
-[RECORD 1]-----+-----
config_dfs_path | voltage.conf
identity | alice@example.com
username | alice
```

## Encrypting, decrypting, and hashing data

Once you have set up authentication with the SecureData Appliance (SDA), call the [VoltageSecureProtect](#) and [VoltageSecureAccess](#) functions to encrypt/hash or decrypt your data, respectively. At a minimum, you pass these functions the value to be encrypted, hashed, or decrypted and value's FPE format as defined in the Voltage SDA. You can also capture these parameters in [SQL Macros](#) and [access policies](#).

### Connecting Vertica to the SecureData appliance

The following example demonstrates how to fetch the SDA client policy with Vertica and then how to set the session parameters for authentication to the SDA.

1. [Add the SecureData CA certificate to Vertica](#).
2. Set the client policy with [VoltageSecureConfigureGlobal](#).

```
=> SELECT VoltageSecureConfigureGlobal(USING PARAMETERS
 policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml')
 OVER ();
```

policy_url	allow_short_fpe	enable_file_cache
https://voltage-pp-0000.example.com/policy/clientPolicy.xml		

(1 row)

3. (Optional) Retrieve the latest version of the client policy with [VoltageSecureRefreshPolicy](#).

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
```

PolicyRefresh
Successfully refreshed policy on node [v_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

4. Set the authentication parameters to authenticate to the SDA as a Vertica user with [ALTER SESSION](#) or [VoltageSecureConfigure](#). For details on this process, see [Configuring access to SecureData](#).

`ALTER SESSION` sets these parameters for the duration of your session and override parameters set in configuration files.

```
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib identity='alice@example.com';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib username='alice';
ALTER SESSION
=> ALTER SESSION SET UDPARAMETER FOR voltagesecurelib shared_secret='my_secret';
ALTER SESSION
```

`VoltageSecureConfigure` saves these parameters to the specified `config_dfs_path`. This configuration file can then be passed to other Voltage functions.

```
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
 username='alice', identity='alice@example.com', store_password=false) OVER ();
```

config_dfs_path	identity	username
voltage.conf	alice@example.com	alice

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS
 format='ssn',
 config_dfs_path='voltage.conf');
```

VoltageSecureProtect
376-69-6789

### Encrypting and decrypting data

[VoltageSecureProtect](#) takes a format-preserving encryption (FPE) format defined in your SDA and VARCHAR data and returns format-preserved ciphertext, which can then be decrypted with [VoltageSecureAccess](#). That is, if the plaintext follows the form of a phone number (###-###-####), the resulting ciphertext will be in the same form. Formats can be customized in various ways, like masking certain values, leaving some part of the string unencrypted, etc.

One of the many predefined formats in the SDA is `ssn` . The `ssn` format encrypts all but the last four digits of the social security number, which can be useful for certain roles like customer support, which may need the last four digits of the SSN to authenticate individuals over the phone.

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='ssn');
VoltageSecureProtect

376-69-6789
(1 row)

=> SELECT VoltageSecureAccess('376-69-6789' USING PARAMETERS format='ssn');
VoltageSecureAccess

123-45-6789
(1 row)
```

Another predefined format is `auto` , which can handle a wide variety of data, including SSNs. In contrast to `ssn` , `auto` is configured in the SDA to encrypt all characters in the plaintext.

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='auto');
VoltageSecureProtect

820-31-5110
(1 row)
```

Note that you can only decrypt ciphertext with the same format that generated it. In this case, ciphertext created with `ssn` must be decrypted with `ssn` . Passing the format `auto` with a ciphertext generated with `ssn` , for instance, would simply return an incorrect plaintext.

#### Encrypting data during load

When handling sensitive data, you often want to encrypt it as you load it so the unencrypted values are never stored in your database.

The following example demonstrates loading data using `COPY` . Suppose you have a data filled with customer information with the following fields: id number, first name, last name, social security number, card verification number, and date of birth:

```
5345,Thane,Ross,559-32-0670,376765616314013,618,05-09-1996
5346,Talon,Wilkins,540-48-0784,4716511603424923,111,09-17-1941
5347,Daquan,Phelps,785-34-0092,342226134491834,294,05-08-1963
5348,Basia,Lopez,011-85-0705,4595818418314603,503,04-29-1940
5349,Kaseem,Hendrix,672-57-0309,4556 078 73 7944,693,03-11-1942
5350,Omar,Lott,825-45-0131,6462 0541 0799 6261,555,02-17-1956
5351,Nell,Cooke,637-50-0105,646 59756 30903 530,818,02-14-1995
5352,Illana,Middleton,831-47-0929,648 23640 86684 267,883,12-29-1949
5353,Garrett,Williamson,408-73-0207,5334 2702 1360 8370,869,11-06-1955
5354,Hanna,Ware,694-97-0394,543 38494 19219 254,586,08-08-1967
```

To encrypt the social security number and the credit card number columns, call `VoltageSecureProtect` to encrypt these columns in the `COPY` statement you use to load the data:

```
=> CREATE TABLE customers (id INTEGER, first_name VARCHAR, last_name VARCHAR,
 ssn VARCHAR(11), cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
```

```
CREATE TABLE
```

```
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
 cc_num_raw FILLER VARCHAR(25), cvv, dob,
 ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS format='ssn',
 config_dfs_path='voltage.conf'),
 cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS format='cc',
 config_dfs_path='voltage.conf'))
 FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
```

```
Rows Loaded
```

```

 100
(1 row)
```

```
=> SELECT * FROM customers ORDER BY id ASC LIMIT 10;
```

```
id | first_name | last_name | ssn | cc_num | cvv | dob
-----+-----+-----+-----+-----+-----+-----
5345 | Thane | Ross | 072-52-0670 | 405939553794013 | 618 | 1996-05-09
5346 | Talon | Wilkins | 348-30-0784 | 5350908688294923 | 111 | 1941-09-17
5347 | Daquan | Phelps | 983-53-0092 | 133383311411834 | 294 | 1963-05-08
5348 | Basia | Lopez | 490-63-0705 | 7979155436134603 | 503 | 1940-04-29
5349 | Kaseem | Hendrix | 268-74-0309 | 3212 314 45 7944 | 693 | 1942-03-11
5350 | Omar | Lott | 872-03-0131 | 4914 1839 6801 6261 | 555 | 1956-02-17
5351 | Nell | Cooke | 785-90-0105 | 332 34312 95233 530 | 818 | 1995-02-14
5352 | Illana | Middleton | 947-60-0929 | 219 06376 36044 267 | 883 | 1949-12-29
5353 | Garrett | Williamson | 333-23-0207 | 1126 1022 5922 8370 | 869 | 1955-11-06
5354 | Hanna | Ware | 661-57-0394 | 106 09915 59049 254 | 586 | 1967-08-08
(10 rows)
```

### Caution

**Always use the same FPE format to encrypt data in a column.** If you use different FPE formats in the same column (such as loading some data using `ssn` and other data using `auto`) there is no way to tell which format was used for any particular row, and properly and improperly encrypted ciphertexts will be indistinguishable.

Encrypting Non-VARCHAR data

VoltageSecureProtect function only encrypts VARCHAR values, so if you need to encrypt other data types, such as DATE or INTEGER, you must cast these values to VARCHAR in your function call and then cast them back to DATE or INTEGER when storing them.

Building off the previous example, the following encrypts the date of birth (dob) column, which holds date type DATE.

```
=> CREATE TABLE customers2 (id INTEGER, first_name VARCHAR, last_name VARCHAR, ssn VARCHAR(11),
 cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
```

```
CREATE TABLE
```

```
=> COPY customers2 (id, first_name, last_name, ssn, cc_num, cvv, dob_raw FILLER DATE,
 dob AS VoltageSecureProtect(dob_raw::VARCHAR USING PARAMETERS
 format='birthday',
 config_dfs_path='voltage.conf'))::DATE)
FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
```

```
Rows Loaded
```

```

 100
(1 row)
```

```
=> SELECT * FROM customers2 ORDER BY id ASC LIMIT 10;
```

```
id | first_name | last_name | ssn | cc_num | cvv | dob
-----+-----+-----+-----+-----+-----+-----
5345 | Thane | Ross | 559-32-0670 | 376765616314013 | 618 | 1902-03-09
5346 | Talon | Wilkins | 540-48-0784 | 4716511603424923 | 111 | 2023-07-22
5347 | Daquan | Phelps | 785-34-0092 | 342226134491834 | 294 | 2091-01-18
5348 | Basia | Lopez | 011-85-0705 | 4595818418314603 | 503 | 1921-08-17
5349 | Kaseem | Hendrix | 672-57-0309 | 4556 078 73 7944 | 693 | 1962-08-23
5350 | Omar | Lott | 825-45-0131 | 6462 0541 0799 6261 | 555 | 1930-01-12
5351 | Nell | Cooke | 637-50-0105 | 646 59756 30903 530 | 818 | 2098-01-01
5352 | Illana | Middleton | 831-47-0929 | 648 23640 86684 267 | 883 | 1956-09-07
5353 | Garrett | Williamson | 408-73-0207 | 5334 2702 1360 8370 | 869 | 2079-03-25
5354 | Hanna | Ware | 694-97-0394 | 543 38494 19219 254 | 586 | 1903-07-16
(10 rows)
```

#### Note

To encrypt dates, you must create your own FPE format. Be sure to match your custom FPE format to standard Vertica date format of YYYY-MM-DD. The example's `birthday` is one such custom format.

Note that you cannot use the `auto` format for DATE types; ciphertext generated by `auto` uses the full range of numbers and letters and only preserves the number of characters and any separators, so the resulting ciphertext cannot typically be cast to a date.

```
=> SELECT VoltageSecureProtect('07-16-1969' USING PARAMETERS format='auto',
 config_dfs_path='/voltagesecure/conf');
```

```
VoltageSecureProtect
```

```

45-86-8651
(1 row)
```

```
=> SELECT VoltageSecureProtect('07-16-1969' USING PARAMETERS format='auto',
 config_dfs_path='/voltagesecure/conf')::DATE;
```

```
ERROR 2992: Date/time field value out of range: "45-86-8651"
```

```
HINT: Perhaps you need a different "datestyle" setting
```

Decrypting values in queries

To decrypt ciphertext stored in tables, call `VoltageSecureAccess` on the encrypted column in your query.

The following example queries a table and decrypts the SSN column:

```
=> SELECT id,
 first_name,
 last_name,
 VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf') AS ssn_plaintext,
 dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
```

id	first_name	last_name	ssn_plaintext	dob
5346	Talon	Wilkins	540-48-0784	1941-09-17
5347	Daquan	Phelps	785-34-0092	1963-05-08
5348	Basia	Lopez	011-85-0705	1940-04-29
5349	Kaseem	Hendrix	672-57-0309	1942-03-11
5350	Omar	Lott	825-45-0131	1956-02-17
5352	Illana	Middleton	831-47-0929	1949-12-29
5353	Garrett	Williamson	408-73-0207	1955-11-06
5354	Hanna	Ware	694-97-0394	1967-08-08
5355	Quinn	Pruitt	818-91-0359	1965-11-14
5356	Clayton	Santiago	102-56-0010	1958-02-02

(10 rows)

Important  
The VoltageSecureAccess function has no way of determining if the values you are passing it are actually encrypted or not; the function simply takes the input and transforms it using the decryption key. If you pass it values from an unencrypted column, you will get back scrambled values. For example:

```
=> SELECT first_name,
 VoltageSecureAccess(first_name USING PARAMETERS format='auto',
 config_dfs_path='/voltagesecure/conf')
 AS decrypted_first_name
FROM customers LIMIT 10;
```

first_name	decrypted_first_name
Omar	Rftd
Illana	Clfkow
Hanna	Bodng
Keith	Hklnw
Constance	Cicgtmgtw
Kirk	Jwdv
Eagan	Hiksm
Branden	Ytqngp
Hope	Tqzc
Keane	Pdcax

(10 rows)

#### Decrypting Non-VARCHAR columns

Like VoltageSecureProtect, VoltageSecureAccess can only handle VARCHAR values. When you decrypt ciphertext from a non-VARCHAR column, you must cast it to a VARCHAR before passing it to VoltageSecureAccess. If your query or client application depends on the original data type of the column, you must then cast the returned plaintext back to the column's original data type.

The following example decrypts the dob column by casting the column data from DATE to VARCHAR, passing it to VoltageSecureAccess, and then casting the plaintext back to DATE.

```
=> SELECT id, first_name, last_name,
 VoltageSecureAccess(dob::VARCHAR USING PARAMETERS format='birthday',
 config_dfs_path='/voltagesecure/conf')::DATE AS dob
 FROM customers2 ORDER BY id LIMIT 10;
id | first_name | last_name | dob
```

```
-----+-----+-----+-----
5345 | Thane | Ross | 1996-05-09
5346 | Talon | Wilkins | 1941-09-17
5347 | Daquan | Phelps | 1963-05-08
5348 | Basia | Lopez | 1940-04-29
5349 | Kaseem | Hendrix | 1942-03-11
5350 | Omar | Lott | 1956-02-17
5351 | Nell | Cooke | 1995-02-14
5352 | Illana | Middleton | 1949-12-29
5353 | Garrett | Williamson| 1955-11-06
5354 | Hanna | Ware | 1967-08-08
(10 rows)
```

### Masking decrypted values

If the ciphertext was created with a format that specifies a form of "masking," plaintexts returned by VoltageSecureAccess can be masked by using the `mask=true` parameter. If you don't specify this parameter, the full plaintext will be returned regardless of the format.

This format, as defined in the Voltage SDA, obscures all but the last two characters of the decrypted plaintext.

```
=> SELECT VoltageSecureAccess('g3kbx6ru19', USING PARAMETERS
 format='maskedFormat',
 config_dfs_path='voltage.conf');
```

```
VoltageSecureAccess
```

```

1234567890
```

```
=> SELECT VoltageSecureAccess('g3kbx6ru19', USING PARAMETERS
 format='maskedFormat',
 config_dfs_path='voltage.conf',
 mask=true);
```

```
VoltageSecureAccess
```

```

XXXXXXXX90
```

### Tweaking ciphertext

Analogous to a [salt](#), you can pass an additional "tweak" value to add to the key used by VoltageSecureProtect to create unique ciphertexts from the same plaintext. This "tweaked" ciphertext can then only be decrypted by passing the same format and "tweak" value to VoltageSecureAccess. Support for this feature is set in the SDA.

The following example uses the custom format `ssn-tweak` and the value `tweakvalue123` to tweak the ciphertext.

```
=> SELECT VoltageSecureProtect('681-09-2913', 'tweakvalue123' USING PARAMETERS
 format='ssn-tweak');
```

```
VoltageSecureProtect
```

```

721-21-2913
```

```
=> SELECT VoltageSecureAccess('721-21-2913', 'tweakvalue123' USING PARAMETERS
 format='ssn-tweak');
```

```
VoltageSecureProtect
```

```

681-09-2913
```

## Tweaking an entire column

A common use case is to use the values from one column to tweak the ciphertext in another.

The following example loads the data in a similar manner to the previous section, but uses the values from the last\_name column to tweak the dates of birth of each customer.

```
=> CREATE TABLE customers (id INTEGER, first_name VARCHAR, last_name VARCHAR, ssn VARCHAR(11),
 cc_num VARCHAR(25), cvv VARCHAR(5), dob DATE);
CREATE TABLE
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
 cc_num_raw FILLER VARCHAR(25), cvv,
 dob_raw FILLER DATE, ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS format='ssn',
 config_dfs_path='voltage.conf'),
 /* cast the dob_raw to VARCHAR and tweak with last_name, then cast back to DATE */
 dob AS VoltageSecureProtect(dob_raw::VARCHAR , last_name USING PARAMETERS format='date-tweak',
 config_dfs_path='voltage.conf')::DATE,
 cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS format='cc', config_dfs_path='voltage.conf'))
 FROM 'customers.csv' DELIMITER ',';
```

Rows Loaded

```

 100
(1 row)
```

```
=> SELECT id, first_name, last_name, dob FROM customers ORDER BY id;
 id | first_name | last_name | dob
```

```
-----+-----+-----+-----
5345 | Thane | Ross | 2086-03-07
5346 | Talon | Wilkins | 1936-06-09
5347 | Daquan | Phelps | 1953-12-01
5348 | Basia | Lopez | 1979-11-30
5349 | Kaseem | Hendrix | 2090-01-07
5350 | Omar | Lott | 1984-07-27
5351 | Nell | Cooke | 2053-03-20
5352 | Illana | Middleton | 1988-03-06
5353 | Garrett | Williamson | 1927-03-03
5354 | Hanna | Ware | 1998-08-28
5355 | James | May | 1941-10-24
(11 rows)
```

To decrypt the column, include the tweak column in the call to VoltageSecureAccess. The tweak column must contain the same data it did when it was used to encrypt the column.

```
=> SELECT id, first_name, last_name,
 VoltageSecureAccess(dob::VARCHAR , last_name USING PARAMETERS format='date-tweak',
 config_dfs_path='voltage.conf')::DATE AS dob
 FROM customers ORDER BY id;
id | first_name | last_name | dob
-----+-----+-----+-----
5345 | Thane | Ross | 1996-05-09
5346 | Talon | Wilkins | 1941-09-17
5347 | Daquan | Phelps | 1963-05-08
5348 | Basia | Lopez | 1940-04-29
5349 | Kaseem | Hendrix | 1942-03-11
5350 | Omar | Lott | 1956-02-17
5351 | Nell | Cooke | 1995-02-14
5352 | Illana | Middleton | 1949-12-29
5353 | Garrett | Williamson | 1955-11-06
5354 | Hanna | Ware | 1967-08-08
5355 | James | May | 1967-08-08
(11 rows)
```

### Tweaking columns with stored procedures

Since tweak values become part of the encryption key, a tweak column's contents must be the same at the time of both encryption and decryption. To avoid losing access to the plaintext, when modifying a tweak column, you must:

1. decrypt the ciphertext
2. modify the tweak column
3. re-encrypt the plaintext data with the contents of the modified tweak column

You can automate this process by using stored procedures. For example, a stored procedure to update a customer's date of birth when tweaked with their last name might be:

```
=> CREATE PROCEDURE update_dob (employee_id INT, tweak_value VARCHAR) AS $$
BEGIN
 PERFORM UPDATE customers
 SET dob = (
 WITH dob_ AS (SELECT VoltageSecureAccess(dob::VARCHAR , last_name
 USING PARAMETERS format='date-tweak', config_dfs_path='voltage.conf')::DATE AS dob
 FROM customers
 WHERE id = employee_id)
 SELECT VoltageSecureProtect(dob::VARCHAR, tweak_value
 USING PARAMETERS format='date-tweak', config_dfs_path='voltage.conf')::DATE
 FROM dob_)
 WHERE ID = employee_id;

 PERFORM UPDATE customers SET last_name = tweak_value WHERE ID = employee_id;

 PERFORM COMMIT;
END;
$$;
```

You can then call the procedure to update the encrypted value and the tweak value:

```
=> CALL update_dob(5349, 'Henderson');
```

### Hashing data

VoltageSecureProtect can also hash your data while preserving its format, which can be useful in contexts where you need to anonymize data to comply with privacy standards while retaining accessibility for client code.

You should keep in mind the following:

- hashing is a one way operation, so the original plaintext is unrecoverable
- the nature of format-preserving hash functions and plaintexts with low entropy (names, dates, SSNs, etc.) mean that collisions are much more likely than with standard hashing functions

The following example encrypts an SSN using a custom FPH format, [ssnHash](#) .

```
=> SELECT VoltageSecureProtect('681-09-2913' USING PARAMETERS
 format='ssnHash',
 config_dfs_path='voltage.conf');
VoltageSecureProtect

841-68-2913
```

## Encapsulating encryption business logic with SQL macros

The [VoltageSecureProtect](#) and [VoltageSecureAccess](#) functions are fairly low-level functions and require a lot of preparation to use correctly. This includes, but is not limited to, information on the data type you're decrypting/encrypting, which Voltage format to use, casting the input to VARCHAR and then back to your desired data type, and identity management. Writing queries with this many moving parts can be tedious.

To streamline this process, you can encapsulate this information in SQL macros and decide its behavior in a more dynamic way with case expressions. This approach offers several benefits:

- You can associate a Voltage format with the data's purpose and Vertica will automatically encrypt and decrypt the value accordingly.
- You can automate the required type casting to and from your desired data type to VARCHAR.
- The [THROW\\_ERROR](#) function can provide a form of input validation for your macros.
- You can specify an [identity](#) for a given case expression during encryption which restricts decryption privileges to the same identity.

### Note

SQL macros are incompatible with User-Defined Transform Functions, such as [VoltageSecureProtectAllKeys](#) .

To view your macros, query the [USER\\_FUNCTIONS](#) system table.

### Encryption and decryption macro templates

In the following macros, the [data\\_purpose](#) parameter describes what the data is used for (e.g. [temperature](#) ) and the [value](#) parameter indicates value being encrypted and its [data\\_type](#) (e.g. INT). The [data\\_type](#) must be the same across the entire macro.

The [data\\_purpose](#) parameter is also associated with both the [voltage\\_format](#) and [voltage\\_identity](#) parameters, which control how the data is encrypted/decrypted and which identity has access to it, respectively.

If you pass into the function a [data\\_purpose](#) without a corresponding case expression, the [THROW\\_ERROR](#) function will return a user-specified error, which itself must be casted to the function's return [data\\_type](#) .

Note that the standard casting operator `::` will terminate the query entirely if it encounters types incompatible with the specified cast, which can be problematic when casting larger datasets. To prevent the query from terminating, you can use the `::!` operator to first attempt the specified cast, but to return a NULL value for incompatible types. For more information, see [Cast failures](#) .

### Encryption macro with VoltageSecureProtect

```
=> CREATE FUNCTION encryptDataType(data_purpose VARCHAR, value data_type) RETURN data_type
AS BEGIN
RETURN(CASE
 WHEN (data_purpose='data_purpose')
 then VoltageSecureProtect(value::VARCHAR USING PARAMETERS
 format='voltage_format',
 identity='voltage_identity')::data_type
 ELSE
 THROW_ERROR('no matching data_purpose')::data_type
 END);
END;
```

### Decryption macro with VoltageSecureAccess

```
=> CREATE FUNCTION decryptDataType(data_purpose VARCHAR, value data_type) RETURN data_type
AS BEGIN
RETURN(CASE
WHEN (data_purpose='data_purpose')
then VoltageSecureAccess(value::VARCHAR USING PARAMETERS
format='voltage_format',
identity='voltage_identity')::data_type
ELSE
THROW_ERROR('no matching data_purpose')::data_type
END);
END;
```

### Example

The following example shows how to manage encryption and decryption for a column with dates of birth. In this case, you might want to define a separate identity for encrypting customer and employee data.

```
=> SELECT * FROM customer_dob;
dates

1955-11-04
1991-12-01
1977-07-07
(3 rows)
```

For encryption, define the following macro.

```
=> CREATE FUNCTION encryptDOB(data_purpose VARCHAR, value DATE) RETURN DATE
AS BEGIN
RETURN
(CASE
--The data_purpose parameter controls which identity is used during encryption;
WHEN (data_purpose='customer')
--Format, identities, and casting from DATE to VARCHAR and back to DATE are all encapsulated in the case expression;
then VoltageSecureProtect(value::VARCHAR USING PARAMETERS
format='birthday',
identity='customer_data@example.com')::DATE
WHEN (data_purpose='employee')
then VoltageSecureProtect(value::VARCHAR USING PARAMETERS
format='birthday',
identity='employee_data@example.com')::DATE
ELSE
THROW_ERROR('Unsupported data_purpose -- You must pass "customer" when
encrypting customer data or "employee" when encrypting employee data')::DATE
--Because the return type of this macro is DATE, THROW_ERROR must also be casted to type DATE;
END);
END;
```

To encrypt the dates column in the customer\_dob table:

```
=> SELECT encryptDOB('customer', dates) FROM customer_dob;
encryptDOB

2048-08-09
1917-03-05
2022-01-07
```

To encrypt a value individually:

```
=> SELECT encryptDOB('customer', '1955-11-04');
encryptDOB

2048-08-09
```

You can define a matching macro for decryption. Since encrypted data can only be decrypted with matching identities, these case expressions use the same `data_purpose` and identities for decryption.

For decryption, define the following macro:

```
=> CREATE FUNCTION decryptDOB(data_purpose VARCHAR, value DATE) RETURN DATE
AS BEGIN
RETURN
(CASE
--The case expressions and parameters must match the ones for encryption;
WHEN (data_purpose='customer')
then VoltageSecureAccess(value::VARCHAR USING PARAMETERS
format='birthday',
identity='customer_data@example.com')::DATE
WHEN (data_purpose='employee')
then VoltageSecureAccess(value::VARCHAR USING PARAMETERS
format='birthday',
identity='employee_data@example.com')::DATE
ELSE
THROW_ERROR('Unsupported data_purpose -- You must pass "customer" when
decrypting customer data or "employee" when decrypting employee data')::DATE
END);
END;
```

To decrypt an encrypted column in a nested call:

```
=> SELECT decryptDOB('customer', encryptDOB('customer', dates)) FROM customer_dob;
decryptDOB

1955-11-04
1991-12-01
1977-07-07
(3 rows)
```

To decrypt a value individually:

```
=> SELECT decryptDOB('customer', '2048-08-09');
decryptDOB

1955-11-04
```

To drop these macros:

```
=> DROP FUNCTION encryptDOB(VARCHAR, DATE);
DROP FUNCTION
=> DROP FUNCTION decryptDOB(VARCHAR, DATE);
DROP FUNCTION
```

## Granting users access to the Voltage SecureData integration functions

By default, Vertica users do not have access to the Voltage SecureData Integration Functions. Users attempting to call the integration functions without the correct privileges will receive the following error:

```
=> SELECT id,
 first_name,
 last_name,
 VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf') AS ssn,
 dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
```

ERROR 6482: Failed to parse Access Policies for table "customers" [Function public.VoltageSecureProtect(varchar) does not exist, or permission is denied for public.VoltageSecureProtect(varchar)]

Users must have EXECUTE access to the integration functions in order to use them. These functions are part of the PUBLIC schema. The functions in the Voltage SecureData integration library are:

Function Signature	Function Type
<a href="#">VoltageSecureAccess</a> (VARCHAR)	Function
<a href="#">VoltageSecureConfigure</a> ()	Transform Function
<a href="#">VoltageSecureProtect</a> (VARCHAR)	Function
<a href="#">VoltageSecureProtectAllKeys</a> (VARCHAR)	Transform Function

The following example demonstrates granting the user named Alice access to the VoltageSecureAccess function to be able to decrypt data.

```
=> \c vmart dbadmin
You are now connected to database "vmart" as user "dbadmin".
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureProtect(VARCHAR) TO alice;
GRANT PRIVILEGE
=> \c vmart alice
You are now connected to database "vmart" as user "alice".
=> SELECT id, first_name, last_name,
 VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf')
 AS ssn,
 dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;
id | first_name | last_name | ssn | dob
-----+-----+-----+-----+-----
5345 | Thane | Ross | 559-32-0670 | 1902-03-09
5348 | Basia | Lopez | 011-85-0705 | 1921-08-17
5349 | Kaseem | Hendrix | 672-57-0309 | 1962-08-23
5350 | Omar | Lott | 825-45-0131 | 1930-01-12

5354 | Hanna | Ware | 694-97-0394 | 1903-07-16
5358 | Mallory | Vaughn | 870-53-0272 | 1961-03-09
5363 | Kirk | Robinson | 155-08-0085 | 1964-06-28
5366 | Branden | Coffey | 709-38-0423 | 1923-06-11
5367 | Raven | Keith | 250-31-0269 | 1918-07-31
(10 rows)
```

See [GRANT \(user defined extension\)](#) for a detailed explanation of granting access to UDxs to users.

Creating roles for SecureData users

Instead of granting access to each function to individual users, you can create roles that you grant access to the functions. Then you can grant users who need to access the SecureData functions access to these roles.

Consider creating at least two roles: one for access to the VoltageSecureConfigure function and another for access to the other functions. In most cases, not all users need to access VoltageSecureConfigure, especially if you choose to create a single, global configuration file. See [Configuring access to SecureData](#) for more information about using VoltageSecureConfigure.

The following example:

- Creates two roles: `secure_data_users`, who are granted access to the protect and access functions, and `secure_data_admins`, who are granted access to the SecureDataConfigure function.
- Grants the `secure_data_user` role to a user named Alice
- Sets the new role as her default role.
- Switches to Alice
- Calls several of the SecureData functions.

```

=> \c vmart dbadmin
You are now connected to database "vmart" as user "dbadmin".
=> CREATE ROLE secure_data_users;
CREATE ROLE
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureAccess(varchar)
 TO secure_data_users;
GRANT PRIVILEGE
=> GRANT EXECUTE ON FUNCTION public.VoltageSecureProtect(varchar)
 TO secure_data_users;
GRANT PRIVILEGE
=> GRANT EXECUTE ON TRANSFORM FUNCTION
 public.VoltageSecureProtectAllKeys(varchar)
 TO secure_data_users;
GRANT PRIVILEGE
=> CREATE ROLE secure_data_admins;
CREATE ROLE
=> GRANT EXECUTE ON TRANSFORM FUNCTION public.VoltageSecureConfigure()
 TO secure_data_admins;
GRANT PRIVILEGE
=> GRANT secure_data_users TO ALICE;
GRANT ROLE
=> ALTER USER alice DEFAULT ROLE secure_data_users;
ALTER USER
=> \c vmart alice
You are now connected to database "vmart" as user "alice".
=> SET ROLE secure_data_users;
SET
=> SELECT VoltageSecureProtect('123-45-6789'
 USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf');
VoltageSecureProtect

376-69-6789
(1 row)
=> SELECT VoltageSecureAccess('376-69-6789'
 USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf');
VoltageSecureAccess

123-45-6789
(1 row)
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
 username='alice', identity='alice@example.com',
) OVER ();
ERROR 3457: Function VoltageSecureConfigure() does not exist, or permission
is denied for VoltageSecureConfigure()
HINT: No function matches the given name and argument types. You may need to
add explicit type casts

```

Note that Alice can use the global configuration file, despite not being able to access the VoltageSecureConfigure function.

#### Note

In the previous example, the global configuration file includes the shared secret or password. See [Configuring access to SecureData](#) for a discussion of the security implications of saving sensitive information to a SecureData configuration file.

You can automate encryption and decryption by creating [access policies](#). These policies let you show users with specific roles unencrypted values while users without those roles see encrypted ones. Alternatively, you can create an access policy that masks unencrypted data stored in the database when queried by users who lack a specific role.

Users do not explicitly call the SecureData integration functions when you create access policies to automatically encrypt and decrypt data. However, they still must have access to the SecureData functions and have any necessary session variables set. See [Configuring access to SecureData](#) and [Granting users access to the Voltage SecureData integration functions](#) for the necessary configuration for the access policies to work. If a user who does not have access to the SecureData integration functions queries a table with an access policy that calls these functions, the query generates an error.

### Automatically decrypting table columns for privileged users

To decrypt an encrypted column automatically, create an access policy for the encrypted column that calls [VoltageSecureAccess](#) if the user has a role enabled. If the user does not have the role enabled, just return the encrypted value.

The following example:

1. Creates a role named see\_ssn and grants it to the user named Alice, as well as granting Alice access to the customers table.
2. Creates an access policy on the customers table's ssn column that decrypts the column's value if the user has the see\_ssn role enabled.
3. Switches to the user named Alice.
4. Queries the customers table, without the see\_ssn role enabled.
5. Enables the see\_ssn role and queries the table again.

```
=> CREATE ROLE see_ssn;
CREATE ROLE

=> GRANT see_ssn TO alice;
GRANT ROLE

=> GRANT ALL ON TABLE customers TO alice;
GRANT PRIVILEGE

=> CREATE ACCESS POLICY ON customers FOR COLUMN ssn
CASE
 WHEN enabled_role('see_ssn') THEN VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf')
 ELSE ssn
END ENABLE;
CREATE ACCESS POLICY

=> \c vmart alice;
Password:
You are now connected to database "vmart" as user "alice".

=> SELECT first_name, last_name, ssn FROM customers WHERE id < 5355 ORDER BY id ASC;
first_name | last_name | ssn
-----+-----+-----
Gil | Reeves | 997-92-0657
Robert | Moran | 715-02-0455
Hall | Rice | 938-83-0659
Micah | Trevino | 495-57-0860
(4 rows)

=> SET ROLE see_ssn;
SET
=> SELECT first_name, last_name, ssn FROM customers WHERE id < 5355 ORDER BY id ASC;
first_name | last_name | ssn
-----+-----+-----
Gil | Reeves | 232-28-0657
Robert | Moran | 725-79-0455
Hall | Rice | 285-90-0659
Micah | Trevino | 853-60-0860
(4 rows)
```

In the above example, you could combine the `see_ssn` role with a role that grants users access to the SecureData integration functions. Users who do not have the `see_ssn` role do not need to have access to the SecureData functions in order to see the encrypted values.

#### Note

The above example assumes that the shared configuration file ( `/voltagesecure/conf` ) contains all of the credentials necessary to authenticate with the SecureData Appliance, including the password or shared secret. This configuration may not be secure enough to meet your requirements. See the caution in [VoltageSecureConfigure](#) for more information. In production use, consider having each privileged user set their identity, username, and password or shared secret in session variables. Unprivileged users do not need to set these values.

#### Automatically encrypting columns for unprivileged users

You can also create access policies that encrypt values. Use this technique to prevent some users from seeing values in columns that aren't sensitive enough to require encryption in the database, but should not be seen by all users. This technique is the opposite of the encryption-on-the-fly: users that have a specific role enabled get the value from the table; if they do not have the role, the access policy encrypts the value.

The following example:

1. Creates a role named `see_dob` and assigns it to the user Alice.
2. Creates an access policy on the `dob` column of the `customers` table. It returns the value in the column if the user has the `see_dob` role active and encrypts the value if not.
3. Switches to the user named Alice.
4. Queries the `customers` table including the `dob` column.
5. Sets the `see_dob` role and queries `customers` again.

```

=> CREATE ROLE see_dob;
CREATE ROLE

=> GRANT see_dob TO alice;
GRANT ROLE

=> CREATE ACCESS POLICY ON customers FOR COLUMN dob
CASE
 WHEN enabled_role('see_dob') THEN dob
 ELSE VoltageSecureProtect(dob::varchar USING PARAMETERS format='birthday',
 config_dfs_path='/voltagesecure/conf')::date
END ENABLE;
CREATE ACCESS POLICY

=> \c vmart alice
Password:
You are now connected to database "vmart" as user "alice".

=> SELECT first_name, last_name, dob FROM customers ORDER BY id ASC LIMIT 10;
first_name | last_name | dob
-----+-----+-----
Gil | Reeves | 2048-08-09
Robert | Moran | 1917-03-05
Hall | Rice | 2022-01-07
Micah | Trevino | 2018-06-01
Kuame | Stephenson | 2053-02-13
Hedda | Cooper | 2002-03-12
MacKenzie | Burks | 2061-10-30
Anne | Marquez | 2078-08-02
Dominic | Avery | 1940-08-10
Alfreda | Mcdaniel | 1904-04-27
(10 rows)

=> SET ROLE see_dob;
SET

=> SELECT first_name, last_name, dob FROM customers ORDER BY id ASC LIMIT 10;
first_name | last_name | dob
-----+-----+-----
Gil | Reeves | 1955-11-04
Robert | Moran | 1991-12-01
Hall | Rice | 1977-07-07
Micah | Trevino | 1980-12-05
Kuame | Stephenson | 1979-09-12
Hedda | Cooper | 1987-05-02
MacKenzie | Burks | 1982-11-07
Anne | Marquez | 1949-07-09
Dominic | Avery | 1976-12-02
Alfreda | Mcdaniel | 1975-02-08
(10 rows)

```

#### Note

The values you pass to `VoltageSecureProtect` and `VoltageSecureAccess` must be `VARCHARS`. In the previous example, the `dob` column's data type is `DATE`, so its value has to be cast to `VARCHAR` when passed to `VoltageSecureProtect`. The encrypted value has to be cast back to a `DATE` value because its output needs to match the table schema.

In the previous example, users who do not have the `see_dob` role enabled must have access to the `SecureData` functions in order to see the masked values. If they do not have access to the `SecureData` functions, querying the `customers` table results in an error message. The following example creates a new user named `Bob` and grants him access to the `customers` table, without any access to the `SecureData` functions.

```

=> CREATE USER bob;
CREATE USER
=> GRANT ALL ON TABLE customers TO bob;
GRANT PRIVILEGE
=> \c vmart bob
You are now connected to database "vmart" as user "bob".
=> SELECT * FROM customers LIMIT 10;
ERROR 6482: Failed to parse Access Policies for table "customers"
[Function public.VoltageSecureProtect(varchar) does not exist, or permission
is denied for public.VoltageSecureProtect(varchar)]

```

## Querying eFPE encrypted columns

You can use a feature in Voltage SecureData called Embedded Format Preserving Encryption to encrypt your data. You choose to use eFPE when you define the format in your SecureData Appliance. This format is slightly different than the standard FPE format. It uses key rotation, and embeds identification information in the encrypted value. Due to these factors, calls to [VoltageSecureProtect](#) using an eFPE format may not result in the same encrypted value, depending on key rotation schedules and the identity of the caller. This feature makes querying columns encrypted using an eFPE format more challenging.

When you want to search a standard FPE encrypted column for a value, you can just encrypt the plain text with `VoltageSecureProtect` and use the output in your query. For example, suppose you want to search for the customers table for an entry with the social security number 559-32-0670. Then you could use the following query:

```

=> SELECT id, first_name, last_name FROM customers
 WHERE ssn = VoltageSecureProtect('559-32-0670' USING PARAMETERS
 format='ssn',
 config_dfs_path='voltage.conf');

```

```

id | first_name | last_name
-----+-----
5345 | Thane | Ross
(1 row)

```

Querying a column that uses eFPE format encryption is not as simple, as you do not know which embedded key was used to encrypt the data. You could just use the `VoltageSecureAccess` function to decrypt the entire contents of the table column and search the result for the value you need. However, this is inefficient, as the SecureData function has to be called for every row of data in the table.

A better solution is to use the [VoltageSecureProtectAllKeys](#) function. This function is similar to `VoltageSecureProtect`. However, instead of returning a single encrypted value, it returns a table containing the value encrypted with each of the keys defined for the eFPE format.

```

=> SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
 format='cc_num',
 config_dfs_path='/voltagesecure/conf')
 OVER ();

```

```

data | protected
-----+-----
376765616314013 | XMVMRU9RJVU4013
376765616314013 | X5FD4KO1UEE4013
376765616314013 | M7ZXTIQVCPB4013
376765616314013 | UBOSC9K3EXZ4013
376765616314013 | ZJ1C50C9L9R4013
(5 rows)

```

In the previous example, the `cc_num` column is encrypted using an eFPE format. The output from `VoltageSecureProtectAllKeys` shows that this eFPE format has 5 keys defined. The content of the protected column contains the same value encrypted with each of the keys.

To use this function in a query for a value in an eFPE column, use a [JOIN](#) on the table you are searching and the result table from `VoltageSecureProtectAllKeys`. The following example demonstrates querying the customers table to find all rows that have a `cc_num` value that matches the unencrypted credit card value 376765616314013.

```
=> SELECT id, first_name, last_name FROM customers3 u
 JOIN (SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
 format='cc_num',
 config_dfs_path='/voltagesecure/conf')
 OVER ()) pak
 ON u.cc_num = pak.protected;
```

```
id | first_name | last_name
```

```
-----+-----+-----
5345 | Thane | Ross
```

```
(1 row)
```

## Voltage SecureData integration function reference

The functions in this section are part of the Vertica `voltagesecure` library for integrating with Voltage SecureData. These functions are automatically installed when you install or upgrade Vertica. However, you must re-install the `voltagesecure` library to distribute the CA certificate to all nodes in the Vertica cluster. See [Verifying the Vertica server's access to the SecureData CA certificate](#) for instructions.

In this section

- [VoltageSecureAccess](#)
- [VoltageSecureConfigure](#)
- [VoltageSecureConfigureGlobal](#)
- [VoltageSecureProtect](#)
- [VoltageSecureProtectAllKeys](#)
- [VoltageSecureRefreshPolicy](#)

### VoltageSecureAccess

Calls SecureData to decrypt ciphertexts encrypted with [VoltageSecureProtect](#).

Syntax

```
VoltageSecureAccess('ciphertext' [, 'tweak'] USING PARAMETERS
 format='format_name'
 [, mask=is_masked]
 [, config_dfs_path='config_file']
 [, identity=sd_identity]);
```

Parameters

<i>ciphertext</i>	A VARCHAR value that was encrypted using SecureData. You must cast other data types (for example DATE values) to VARCHAR when calling this function.
<i>tweak</i>	<p>VARCHAR value analogous to a <a href="#">salt</a> that allows equivalent * <i>plaintext</i> *s to produce different ciphertexts. The same <i>tweak</i> value must for encryption and decryption of a given plaintext.</p> <p>When encrypting or hashing an entire column, you can pass another column for a set of <i>tweak</i> values.</p> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p><b>Caution</b> Never use two columns as tweak values for each other or else the original plaintext for both columns will be unrecoverable.</p> </div>
<i>format_name</i>	A string specifying the original FPE format used to generate the ciphertext. Note that SecureData has no way to tell if the value passed to it was actually encrypted or not, or what FPE format was used.

<i>is_masked</i>	A boolean, whether to mask the value when decrypting the <i>ciphertext</i> . Masking is defined on a per-format basis on the SecureData Appliance.  Note that since masking is optional, you must specify whether to decrypt with masking enabled. If you omit the masking parameter, the plaintext will be unmasked by default:
<i>config_file</i>	String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See <a href="#">Configuring access to SecureData</a> . Any values set in session parameters override the values in this file.
<i>sd_identity</i>	A string containing the identity to use when decrypting the data. Because SecureData uses the identity to determine encryption keys, this identity must match the identity used to encrypt the data. If supplied, this value overrides any identity value set in the configuration file or session parameter.

## Examples

The following example decrypts a Social Security Number (SSN) originally encrypted with a predefined format.

```
=> SELECT VoltageSecureAccess('376-69-6789' USING PARAMETERS format='ssn');

VoltageSecureAccess

123-45-6789
(1 row)
```

This example demonstrates decrypting an encrypted column within a query.

```
=> SELECT id,
 first_name,
 last_name,
 VoltageSecureAccess(ssn USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf') AS ssn,
 dob
FROM customers
WHERE dob < '1970-1-1'
ORDER BY id ASC
LIMIT 10;

id | first_name | last_name | ssn | dob
-----+-----+-----+-----+-----
5346 | Talon | Wilkins | 540-48-0784 | 1941-09-17
5347 | Daquan | Phelps | 785-34-0092 | 1963-05-08
5348 | Basia | Lopez | 011-85-0705 | 1940-04-29
5349 | Kaseem | Hendrix | 672-57-0309 | 1942-03-11
5350 | Omar | Lott | 825-45-0131 | 1956-02-17
5352 | Illana | Middleton | 831-47-0929 | 1949-12-29
5353 | Garrett | Williamson | 408-73-0207 | 1955-11-06
5354 | Hanna | Ware | 694-97-0394 | 1967-08-08
5355 | Quinn | Pruitt | 818-91-0359 | 1965-11-14
5356 | Clayton | Santiago | 102-56-0010 | 1958-02-02
(10 rows)
```

The following example decrypts Unicode using a predefined format. For a full list of predefined formats, consult the Voltage SecureData documentation.

```
=> SELECT VoltageSecureAccess('607-0d1cç-ふてびねら' using parameters format='PREDEFINED::JU_AUTO_TYPE');
```

```
VoltageSecureAccess
```

```

123-Hello-こんにちは
```

Decrypt a SSN ciphertext with the original FPE format and tweak value:

```
=> SELECT VoltageSecureAccess('721-21-2913', 'tweakvalue123' USING PARAMETERS
 format='ssn-tweak',
 config_dfs_path='voltage.conf');
```

```
VoltageSecureProtect
```

```

681-09-2913
```

Decrypt a ciphertext that was encrypted with a masking format. This format obscures all but the last two characters of the decrypted plaintext.

```
=> SELECT VoltageSecureAccess('g3kxb6ru19', USING PARAMETERS
 format='maskedFormat',
 config_dfs_path='voltage.conf');
```

```
VoltageSecureAccess
```

```

1234567890
```

```
=> SELECT VoltageSecureAccess('g3kxb6ru19', USING PARAMETERS
 format='maskedFormat',
 config_dfs_path='voltage.conf',
 mask=true);
```

```
VoltageSecureAccess
```

```

XXXXXXXXX90
```

## VoltageSecureConfigure

Saves SecureData user access configuration parameters to a file in the Vertica Distributed File System (DFS). You then pass the file's name to the other SecureData integration functions. This function can store the configuration file in the user's own DFS directory or in a globally-accessible file named [/voltagesecure/conf](#).

Syntax

```
VoltageSecureConfigure(USING PARAMETERS config_dfs_path='filename'
 [, identity=sd_identity]
 [, store_password=Boolean]
 [, store_shared_secret=Boolean]
 [, username=sd_user]
) OVER ();
```

Parameters

<code>config_dfs_path = 'filename'</code>	Required. A string containing the path for the configuration file in DFS. This is either: <ul style="list-style-type: none"> <li>A file name (without any path information). The function automatically stores the file in a DFS directory named for the user. Creating this directory prevents different user's files from overwriting one another.</li> <li>The absolute path <code>/voltagesecure/conf</code>. All users can use this file in calls to the other functions in the SecureData library. This path is the only absolute one that VoltageSecureConfigure allows for this parameter.</li> </ul>
<code>identity= sd_boolean</code>	A string containing identity to use with the SecureData Appliance. This is usually in the form of an email address. When SecureData uses LDAP authentication, it uses this value to authenticate the user.
<code>store_password= Boolean</code>	A Boolean value. When set to true, Vertica stores the LDAP password stored in the password session parameter in the configuration file. Defaults to false.
<code>store_shared_secret= Boolean</code>	A Boolean value. When set to true, Vertica stores the shared secret set in the shared_secret session parameter in the configuration file. Defaults to false.
<code>username= sd_user</code>	A string containing the user name for authenticating with SecureData.

#### Notes

- Any SecureData session variables that are set override values from the configuration file. See [Configuring access to SecureData](#) for more information.
- The SecureData integration only supports one configuration for the SecureData Appliance at a time.
- Under normal circumstances, users are not able to directly read data from files stored in DFS. However, all users who have access to UDX functions that read from the DFS could access these files from within Vertica. In addition, these files are stored as plain text in every node's file system. Anyone with the proper file system access on the nodes can read the file's contents. You should take both of these facts into consideration when deciding whether to store sensitive information such as passwords or shared secrets in either the shared or per-user configuration files.

#### Example

The following example demonstrates saving configuration information to a configuration file named `voltage.conf` in the user's own Vertica DFS directory.

```
=> \x
Expanded display is on.
=> SELECT VoltageSecureConfigure(USING PARAMETERS config_dfs_path='voltage.conf',
 username='alice', identity='alice@example.com', store_password=false
) OVER ();
-[RECORD 1]-----+-----
config_dfs_path | voltage.conf
identity | alice@example.com
username | alice
```

#### VoltageSecureConfigureGlobal

Saves global SecureData access configuration parameters for all users to a file in the Vertica Distributed File System (DFS). This function stores the configuration file file named `/voltagesecure/conf.global` in the distributed file system (DFS). You must use this function to configure at least the SecureData policy URL before you can use any of the other Voltage SecureData integration functions.

To refresh the client policy, see [VoltageSecureRefreshPolicy](#).

#### Syntax

```
VoltageSecureConfigureGlobal(USING PARAMETERS policy_url=url
 [, allow_short_fpe=Boolean]
 [, allow_file_cache=Boolean]
 [, network_timeout=Integer]
) OVER ();
```

#### Parameters

<i>policy_url= url</i>	A string containing the URL of the SecureData policy file. The Vertica SecureData library uses the contents of this file, such as the formats that the SecureData Appliance supports. It also uses the URL of this file to determine the location of the SecureData Appliance.
<i>allow_short_fpe= Boolean</i>	A Boolean value. When set to True, SecureData ignores the lower length limit for encoding FPE values. Usually, SecureData does not use FPE to encrypt data shorter than a lower limit (usually, 8 bits). See the <i>SecureData Architecture Guide</i> 's section on Data Length Restrictions for more information.
<i>enable_file_cache= Boolean</i>	A Boolean value. When set to True, Vertica caches the SecureData policy file and encryption keys to disk, rather than just to memory. Defaults to false.
<i>network_timeout= Integer</i>	An Integer value. Configures the network timeout in seconds. Defaults to its maximum value of 300 seconds.

Example  
 To set the policy URL to <https://voltage-pp-0000.example.com/policy/clientPolicy.xml> and set the network timeout to 200 seconds:

```
=> SELECT VoltageSecureConfigureGlobal(USING PARAMETERS
 policy_url='https://voltage-pp-0000.example.com/policy/clientPolicy.xml',
 NETWORK_TIMEOUT=200)
 OVER ();
```

policy_url	allow_short_fpe	enable_file_cache	network_timeout
https://voltage-pp-0000.example.com/policy/clientPolicy.xml			200

(1 row)

To view the current policy:

```
=> SELECT VoltageSecureConfigureGlobal() OVER();
```

policy_url	allow_short_fpe	enable_file_cache	network_timeout
https://voltage-pp-0000.example.com/policy/clientPolicy.xml			200

(1 row)

Manually refresh the client policy across the nodes:

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
```

PolicyRefresh

---

Successfully refreshed policy on node [v\_sandbox\_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

### VoltageSecureProtect

Calls SecureData to encrypt or hash a value while preserving the structure of the original plaintext.

#### Syntax

```
VoltageSecureProtect('plaintext' [, 'tweak'] USING PARAMETERS
 format='format_name'
 [, config_dfs_path='config_file']
 [, identity=sd_identity]);
```

#### Parameters

<i>plaintext</i>	VARCHAR value to encrypt. You must cast other data types (for example DATE values) to VARCHAR when calling this function.  NULL values return NULL.
------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------

<i>tweak</i>	<p>VARCHAR value analogous to a <a href="#">salt</a> that allows equivalent * <i>plaintext</i> *s to produce different ciphertexts. The same <i>tweak</i> value must for encryption and decryption of a given plaintext.</p> <p>When encrypting or hashing an entire column, you can pass another column for a set of <i>tweak</i> values.</p> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p><b>Caution</b> Never use two columns as tweak values for each other or else the original plaintext for both columns will be unrecoverable.</p> </div>
<i>format_name</i>	<p>String specifying a format-preserving encryption (FPE) or format-preserving hash (FPH) format to encrypt or hash the <i>plaintext</i>.</p> <p>To encrypt your data, pass an FPE format defined in your SecureData Appliance.</p> <p>To hash your data, pass an FPH format defined in your SecureData Appliance (version 6.6+). Note that hashing operations are one-way and cannot be reversed with <a href="#">VoltageSecureAccess</a>.</p> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p><b>Caution</b> <b>Always use the same FPE format to encrypt data in a column.</b> If you use different FPE formats in the same column (such as loading some data using <i>ssn</i> and other data using <i>auto</i> ) there is no way to tell which format was used for any particular row, and properly and improperly encrypted ciphertexts will be indistinguishable.</p> </div>
<i>config_file</i>	<p>String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See <a href="#">Configuring access to SecureData</a>. Any values set in session parameters override the values in this file.</p>
<i>sd_identity</i>	<p>String containing the identity to use when authenticating with SecureData. SecureData uses this value as a basis for the encryption key. This value usually takes the form of an email address. If supplied, it overrides any values set in the configuration file or session parameters.</p>

### Examples

Encrypt a social security number (SSN) value using both the *ssn* and *auto* FPE formats (this example assumes that all of the necessary SecureData authentication information has been set in session variables):

```
=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='ssn');
VoltageSecureProtect

376-69-6789
(1 row)

=> SELECT VoltageSecureProtect('123-45-6789' USING PARAMETERS format='auto');
VoltageSecureProtect

820-31-5110
(1 row)
```

Encrypt two table columns in a COPY statement, authenticating to the SecureData Appliance with the user's private configuration file saved in DFS:

```
=> COPY customers (id, first_name, last_name, ssn_raw FILLER VARCHAR(11),
 cc_num_raw FILLER VARCHAR(25), cvv, dob,
 ssn AS VoltageSecureProtect(ssn_raw USING PARAMETERS
 format='ssn',
 config_dfs_path='voltage.conf'),
 cc_num AS VoltageSecureProtect(cc_num_raw USING PARAMETERS
 format='cc',
 config_dfs_path='voltage.conf'))
FROM '/home/dbadmin/customer_data.csv' DELIMITER ',';
```

Rows Loaded

```

 100
(1 row)
```

Query for a particular value in an encrypted column:

```
=> SELECT id, first_name, last_name FROM customers
 WHERE ssn = VoltageSecureProtect('559-32-0670' USING PARAMETERS
 format='ssn',
 config_dfs_path='voltage.conf');
```

```
id | first_name | last_name
-----+-----+-----
5345 | Thane | Ross
(1 row)
```

Encrypting NULL values returns NULL:

```
=> CREATE TABLE nulltable(n VARCHAR (20));
=> INSERT INTO nulltable VALUES (NULL);

=> SELECT VoltageSecureProtect(n USING PARAMETERS format='auto') FROM nulltable;
```

```
VoltageSecureProtect

(1 row)
```

Encrypt a Unicode string using a predefined format. For a full list of predefined formats, consult the Voltage SecureData documentation.

```
=> SELECT VoltageSecureProtect('123-Hello-こんにちは' USING PARAMETERS format='PREDEFINED::JU_AUTO_TYPE');
```

```
VoltageSecureProtect

607-Ôdiçç-ぶてびねら
```

Encrypt a SSN with a tweak value:

```
=> SELECT VoltageSecureProtect('681-09-2913', 'tweakvalue123' USING PARAMETERS
 format='ssn-tweak');
```

```
VoltageSecureProtect

721-21-2913
```

```
=> SELECT VoltageSecureAccess('721-21-2913', 'tweakvalue123' USING PARAMETERS
 format='ssn-tweak');
```

```
VoltageSecureProtect

681-09-2913
```

Hash a SSN with a FPH format and a tweak value:

```
=> SELECT VoltageSecureProtect('681-09-2913', 'tweakvalue123' USING PARAMETERS
 format='ssnHash',
 config_dfs_path='voltage.conf');
VoltageSecureProtect

841-68-2913
```

## VoltageSecureProtectAllKeys

This function helps you locate values in a column encrypted using an Embedded Format Preserving Encryption (eFPE) format. These formats use key rotation, so the encrypted value you get back for a piece of plain text changes over time. You pass this function an unencrypted value. It returns a table consisting of two columns: the unencrypted value and the value encrypted with each of the keys defined for the eFPE. The number of rows in the table are determined by the number of keys the eFPE format contains. Usually, you use the output of this function in a join to locate a matching encrypted value in a table.

Syntax

```
VoltageSecureProtectAllKeys(value USING PARAMETERS format='eFPE_format'
 [, config_dfs_path=config_file]
 [, identity=sd_identity])
```

Parameters

<i>value</i>	VARCHAR containing the value to encrypt. You must cast other data types (for example DATE values) to VARCHAR when calling this function.
<i>format=</i> <i>eFPE_format</i>	String containing the name of an eFPE format defined by SecureData. This format must be an eFPE format defined by your SecureData Appliance, or the function returns an error. This format must also match the format of value. VoltageSecureProtectAllKeys returns an error if <i>value</i> 's format does not match the one you specify in <i>eFPE_format</i> .
<i>config_dfs_path=</i> <i>config_file</i>	String containing the file name of the configuration file to use when authenticating with the SecureData appliance. You must create this file using VoltageSecureConfigure. If you do not supply this parameter, you must set session parameters to configure access to SecureData. See <a href="#">Configuring access to SecureData</a> . Any values set in session parameters override the values in this file.
<i>identity=</i> <i>sd_identity</i>	String containing the identity to use when authenticating with SecureData. SecureData uses this value as a basis for the encryption key. This value usually takes the form of an email address. If supplied, it overrides any values set in the configuration file or session parameters.

Examples

The following example demonstrates a simple call to VoltageSecureProtectAllKeys.

```
=> SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
 format='cc_num',
 config_dfs_path='/voltagesecure/conf')
OVER ();

data | protected
-----+-----
376765616314013 | XMVMRU9RJVU4013
376765616314013 | X5FD4KO1UEE4013
376765616314013 | M7ZXTIQVCPB4013
376765616314013 | UBOSC9K3EXZ4013
376765616314013 | ZJ1C50C9L9R4013
(5 rows)
```

In this example, the cc\_num eFPE format has five keys defined for it, so the return value is a table containing five rows.

The following example shows a more common use: querying a table column that is encrypted using an eFPE format.

```
=> SELECT id, first_name, last_name FROM customers3 u
JOIN (SELECT VoltageSecureProtectAllKeys('376765616314013' USING PARAMETERS
 format='cc_num',
 config_dfs_path='/voltagesecure/conf')
OVER ()) pak
ON u.cc_num = pak.protected;

id | first_name | last_name
-----+-----
5345 | Thane | Ross
(1 row)
```

In the previous example, the customers3 table is joined to the output from VoltageSecureProtectAllKeys. Any rows in the customers3 table where the encrypted cc\_num column value matches values from the protected column of VoltageSecureProtectAllKeys matches appear in the output.

This function returns an error if you use it on a non-eFPE format:

```
=> SELECT first_name, last_name, ssn FROM customers u
JOIN (
SELECT VoltageSecureProtectAllKeys('232-28-0657' USING PARAMETERS format='ssn',
 config_dfs_path='/voltagesecure/conf')
OVER ()
)
pak ON u.ssn = pak.protected;
ERROR 5861: Error calling processPartition() in User Function VoltageSecureProtectAllKeys
at [ProtectAllKeys.cpp:21], error code: 1711, message: Error getting key numbers:
eFPE format required
```

### VoltageSecureRefreshPolicy

Immediately refreshes the client policy on the initiator node. Policies on non-initiator nodes are refreshed the next time a Voltage function is called on them.

Syntax

```
VoltageSecureRefreshPolicy()
```

Parameters

None

## Example

Manually refresh the client policy across the nodes:

```
=> SELECT VoltageSecureRefreshPolicy() OVER ();
 PolicyRefresh
```

Successfully refreshed policy on node [v\_sandbox\_node0001]. Policy on other nodes will be refreshed the next time a Voltage operation is run on them.

(1 row)

## SQL reference

Vertica offers a robust set of SQL elements that allow you to manage and analyze massive volumes of data quickly and reliably, including:

- [Language elements](#) such as keywords, operators, expressions, predicates, and hints
- [Data types](#) including complex types
- [Functions](#) including Vertica-specific functions that take advantage of Vertica's unique column-store architecture
- [SQL statements](#) that let you write robust queries to quickly return large volumes of data

In this section

- [System limits](#)
- [Language elements](#)
- [Data types](#)
- [Configuration parameters](#)
- [File systems and object stores](#)
- [Functions](#)
- [Statements](#)
- [Vertica system tables](#)

## System limits

This section describes system limits on the size and number of objects in a Vertica database. In most cases, computer memory and disk drive are the limiting factors.

Item	Maximum
Nodes	128 (without Vertica assistance)
Database size	Dependent on maximum disk configuration, approximately: <i>numFiles * platformFileSize</i>
Table size	Smaller of: <ul style="list-style-type: none"><li>• <math>2^{64}</math> rows per node</li><li>• <math>2^{63}</math> bytes per column</li></ul>
Row size	$(2^{31}) - 1$  Row size is approximately the sum of its maximum column sizes. For example, a VARCHAR(80) has a maximum size of 80 bytes.
Key size	Dependent on row size

Tables/projections per database	Dependent on physical RAM, as the catalog must fit in memory.
Concurrent connections per node	Dependent on physical RAM (or threads per process), typically 1024 <b>Default:</b> 50
Concurrent connections per cluster	Dependent on physical RAM of a single node (or threads per process), typically 1024
Columns per table/view	9800
Arguments per function call	9800
Rows per load	$2^{63}$
ROS containers per projection	1024  See <a href="#">Minimizing partitions</a> .
Length of fixed-length column	65000 bytes
Length of variable-length column	32 MB
Length of basic names	128 bytes. Basic names include table names, column names, etc.
Query length	None
Depth of nesting subqueries	None in <b>FROM</b> , <b>WHERE</b> , and <b>HAVING</b> clauses

## Language elements

The following topics provide detailed descriptions of the language elements and conventions of Vertica SQL.

In this section

- [Keywords](#)
- [Identifiers](#)
- [Literals](#)
- [Operators](#)
- [Expressions](#)
- [Lambda functions](#)
- [Predicates](#)
- [Hints](#)
- [Window clauses](#)

### Keywords

Keywords are words that have a specific meaning in the SQL language. Every SQL statement contains one or more keywords. Although SQL is not case-sensitive with respect to keywords, they are generally shown in uppercase letters throughout this documentation for readability purposes.

#### Note

If you use a keyword as the name of an identifier or an alias in your SQL statements, you may have to qualify the keyword with **AS** or double-quotes. Vertica requires **AS** or double-quotes for certain reserved and non-reserved words to prevent confusion with expression syntax, or where the use of a word would be ambiguous.

Many keywords are also reserved words.

Vertica recommends that you not use reserved words as names for objects, or as identifiers. Including reserved words can make your SQL statements confusing. Reserved words that are used as names for objects or identifiers must be enclosed in double-quotes.

#### Note

All reserved words are also keywords, but Vertica can add reserved words that are not keywords. A reserved word can simply be a word that is reserved for future use.

#### Non-reserved keywords

Non-reserved keywords have a special meaning in some contexts, but can be used as identifiers in others. You can use non-reserved keywords as aliases—for example, **SOURCE** :

```
=> SELECT my_node AS SOURCE FROM nodes;
```

#### Note

Vertica uses several non-reserved keywords in [directed queries](#) to specify special join types. You can use these keywords as table aliases only if they are double-quoted; otherwise, double-quotes can be omitted:

- **ANTI**
- **NULLAWARE**
- **SEMI**
- **SEMIALL**
- **UNI**

#### Viewing the list of reserved and non-reserved keywords

To view the current list of Vertica reserved and non-reserved words, query system table [KEYWORDS](#). Vertica lists keywords alphabetically and identifies them as reserved (R) or non-reserved (N).

For example, the following query gets all reserved keywords that begin with B:

```
=> SELECT * FROM keywords WHERE reserved = 'R' AND keyword ilike 'B%';
```

```
keyword | reserved
```

```
-----+-----
BETWEEN | R
BIGINT | R
BINARY | R
BIT | R
BOOLEAN | R
BOTH | R
(6 rows)
```

#### Identifiers

Identifiers (names) of objects such as schema, table, projection, column names, and so on, can be up to 128 bytes in length.

#### Unquoted identifiers

Unquoted SQL identifiers must begin with one of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (`_`)

Subsequent characters in an identifier can be any combination of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (`_`)
- Digits(0–9)
- Unicode letters (letters with diacriticals or not in the Latin alphabet), unsupported for model names
- Dollar sign (`$`), unsupported for model names

### Caution

The SQL standard does not support dollar sign in identifiers, so usage can cause application portability problems.

## Quoted identifiers

### Note

Quoted identifiers are not supported for model names

Identifiers enclosed in double quote ( " ) characters can contain any character. If you want to include a double quote, you need a pair of them; for example """". You can use names that would otherwise be invalid—for example, names that include only numeric characters ( "123" ) or contain space characters, punctuation marks, and SQL or [Vertica-reserved](#) keywords. For example:

```
CREATE SEQUENCE "my sequence!";
```

Double quotes are required for non-alphanumerics and SQL keywords such as "1time", "Next week" and "Select".

## Case sensitivity

Identifiers are not case-sensitive. Thus, identifiers "ABC", "ABc", and "aBc" are synonymous, as are ABC, ABc, and aBc.

## Non-ASCII characters

Vertica accepts non-ASCII UTF-8 Unicode characters for table names, column names, and other identifiers, extending the cases where upper/lower case distinctions are ignored (case-folded) to all alphabets, including Latin, Cyrillic, and Greek.

For example, the following [CREATE TABLE](#) statement uses the ß (German eszett) in the table name:

```
=> CREATE TABLE straÙe(x int, y int);
CREATE TABLE
```

## Identifiers are stored as created

SQL identifiers, such as table and column names, are not converted to lowercase. They are stored as created, and references to them are resolved using case-insensitive compares. For example, the following statement creates table ALLCAPS .

```
=> CREATE TABLE ALLCAPS(c1 varchar(30));
=> INSERT INTO ALLCAPS values('upper case');
```

The following statements are variations of the same query:

```
=> SELECT * FROM ALLCAPS;
=> SELECT * FROM allcaps;
=> SELECT * FROM "allcaps";
```

The three queries all return the same result:

```
c1

upper case
(1 row)
```

Note that Vertica returns an error if you try to create table AllCaps :

```
=> CREATE TABLE AllCaps(c1 varchar(30));
ROLLBACK: table "AllCaps" already exists
```

See [QUOTE\\_IDENT](#) for additional information.

## Literals

Literals are numbers or strings used in SQL as constants. Literals are included in the select-list, along with expressions and built-in functions and can also be constants.

Vertica provides support for number-type literals (integers and numerics), string literals, VARBINARY string literals, and date/time literals. The various

string literal formats are discussed in this section.

In this section

- [Number-type literals](#)
- [String literals](#)
- [Date/time literals](#)

Number-type literals

Vertica supports three types of numbers: integers, numerics, and floats.

- [Integers](#) are whole numbers less than  $2^{63}$  and must be digits.
- [Numerics](#) are whole numbers larger than  $2^{63}$  or that include a decimal point with a precision and a scale. Numerics can contain exponents. Numbers that begin with 0x are hexadecimal numerics.

Numeric-type values can also be generated using casts from character strings. This is a more general syntax. See the Examples section below, as well as [Data type coercion operators \(CAST\)](#).

Syntax

```
digits
digits.[digits] | [digits].digits
digits e[+]digits | [digits].digits e[+]digits | digits.[digits] e[+]digits
```

Parameters

**digits**

One or more numeric characters, 0 through 9

**e**

Exponent marker

Notes

- At least one digit must follow the exponent marker ( **e** ), if **e** is present.
- There cannot be any spaces or other characters embedded in the constant.
- Leading plus (+) or minus (-) signs are not considered part of the constant; they are unary operators applied to the constant.
- In most cases a numeric-type constant is automatically coerced to the most appropriate type depending on context. When necessary, you can force a numeric value to be interpreted as a specific data type by casting it as described in [Data type coercion operators \(CAST\)](#).
- Floating point literals are not supported. If you specifically need to specify a float, you can cast as described in [Data type coercion operators \(CAST\)](#).
- Vertica follows the IEEE specification for floating point, including NaN (not a number) and Infinity (Inf).
- A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.
- Dividing INTEGERS (x / y) yields a NUMERIC result. You can use the // operator to truncate the result to a whole number.

Examples

The following are examples of number-type literals:

```
42
3.5
4.
.001
5e2
1.925e-3
```

Scientific notation :

```
=> SELECT NUMERIC '1e10';
?column?

10000000000
(1 row)
```

**BINARY** scaling :

```
=> SELECT NUMERIC '1p10';
?column?
```

```

1024
```

```
(1 row)
```

```
=> SELECT FLOAT 'Infinity';
```

```
?column?
```

```

Infinity
```

```
(1 row)
```

The following examples illustrated using the / and // operators to divide integers:

```
=> SELECT 40/25;
```

```
?column?
```

```

1.60000000000000000000
```

```
(1 row)
```

```
=> SELECT 40//25;
```

```
?column?
```

```

1
```

```
(1 row)
```

[Data type coercion](#)

String literals

String literals are string values surrounded by single or double quotes. Double-quoted strings are subject to the backslash, but single-quoted strings do not require a backslash, except for `\` and `\\`.

You can embed single quotes and backslashes into single-quoted strings.

To include other backslash (escape) sequences, such as `\t` (tab), you must use the double-quoted form.

Precede single-quoted strings with a space between the string and its preceding word, since single quotes are allowed in identifiers.

See also

- [SET STANDARD\\_CONFORMING\\_STRINGS](#)
- [SET ESCAPE\\_STRING\\_WARNING](#)
- [Internationalization parameters](#)
- [Implement locales for international data sets](#)

In this section

- [Character string literals](#)
- [Dollar-quoted string literals](#)
- [Unicode string literals](#)
- [VARBINARY string literals](#)
- [Extended string literals](#)

Character string literals

Character string literals are a sequence of characters from a predefined character set, enclosed by single quotes.

Syntax

```
'character-seq'
```

Parameters

***character-seq***

Arbitrary sequence of characters

Embedded single quotes

If a character string literal includes a single quote, it must be doubled. For example:

```
=> SELECT 'Chester's gorilla';
?column?
```

```

Chester's gorilla
(1 row)
```

Standard-conforming strings and escape characters

Vertica uses standard-conforming strings as specified in the SQL standard, so backslashes are treated as string literals and not escape characters.

#### Note

Earlier versions of Vertica did not use standard conforming strings, and backslashes were always considered escape sequences. To revert to this older behavior, set the configuration parameter [StandardConformingStrings](#) to 0. You can also use the [EscapeStringWarning](#) parameter to locate back slashes which have been incorporated into string literals, in order to remove them.

#### Examples

```
=> SELECT 'This is a string';
?column?
```

```

This is a string
(1 row)
```

```
=> SELECT 'This \is a string';
```

```
WARNING: nonstandard use of escape in a string literal at character 8
```

```
HINT: Use the escape string syntax for escapes, e.g., E'\n'.
```

```
?column?
```

```

This is a string
(1 row)
```

```
vmartdb=> SELECT E'This \is a string';
```

```
?column?
```

```

This is a string
```

```
=> SELECT E'This is a \n new line';
```

```
?column?
```

```

This is a
new line
(1 row)
```

```
=> SELECT 'String"s characters';
```

```
?column?
```

```

String's characters
(1 row)
```

See also

- [SET STANDARD\\_CONFORMING\\_STRINGS](#)
- [SET ESCAPE\\_STRING\\_WARNING](#)
- [Implement locales for international data sets](#)

Dollar-quoted string literals

Dollar-quoted string literals are rarely used, but are provided here for your convenience.

The standard syntax for specifying string literals can be difficult to understand. To allow more readable queries in such situations, Vertica SQL provides **dollar quoting**. Dollar quoting is not part of the SQL standard, but it is often a more convenient way to write complicated string literals than the standard-compliant single quote syntax.

Syntax

```
$$characters$$
```

Parameters

## characters

Arbitrary sequence of characters bounded by paired dollar signs ( \$\$ )

Dollar-quoted string content is treated as a literal. Single quote, backslash, and dollar sign characters have no special meaning within a dollar-quoted string.

### Notes

A dollar-quoted string that follows a keyword or identifier must be separated from the preceding word by whitespace; otherwise, the dollar-quoting delimiter is taken as part of the preceding identifier.

### Examples

```
=> SELECT $$Fred's\n car$$;
?column?
```

```

Fred's\n car
(1 row)
```

```
=> SELECT 'SELECT 'fact';'
ERROR: syntax error at or near "' at character 21
LINE 1: SELECT 'SELECT 'fact';'
```

```
=> SELECT 'SELECT $$fact';$$;
?column?
```

```

SELECT $$fact
(1 row)
```

```
=> SELECT 'SELECT "fact";'
?column?
```

```

SELECT 'fact';
(1 row)
```

## Unicode string literals

### Syntax

```
U&'characters' [UESCAPE '<Unicode escape character>']
```

### Parameters

#### characters

Arbitrary sequence of UTF-8 characters bounded by single quotes (')

#### Unicode escape character

A single character from the source language character set other than a hexit, plus sign (+), quote ('), double quote ("), or white space

### Using standard conforming strings

With [StandardConformingStrings](#) enabled, Vertica supports SQL standard Unicode character string literals (the character set is UTF-8 only).

Before you enter a Unicode character string literal, enable standard conforming strings in one of the following ways.

- To enable for all sessions, update the configuration parameter [StandardConformingStrings](#).
- To treat backslashes as escape characters for the current session, use the [SET STANDARD\\_CONFORMING\\_STRINGS](#) statement.

See also [Extended String Literals](#).

### Examples

To enter a Unicode character in hexadecimal, such as the Russian phrase for "thank you, use the following syntax:

```
=> SET STANDARD_CONFORMING_STRINGS TO ON;
=> SELECT U&'\0441\043F\0430\0441\0438\0431\043E' as 'thank you';
thank you

спасибо
(1 row)
```

To enter the German word **müde** (where **u** is really u-umlaut) in hexadecimal:

```
=> SELECT U&'m\00fcde';
?column?

müde
(1 row)
=> SELECT 'ü';
?column?

ü
(1 row)
```

To enter the **LINEAR B IDEOGRAM B240 WHEELED CHARIOT** in hexadecimal:

```
=> SELECT E'\xF0\x90\x83\x8C';
?column?

(wheeled chariot character)
(1 row)
```

#### Note

Not all fonts support the wheeled chariot character.

- [Implement locales for international data sets](#)

VARBINARY string literals

VARBINARY string literals allow you to specify hexadecimal or binary digits in a string literal.

Syntax

```
X''
B''
```

Parameters

#### **X or x**

Specifies hexadecimal digits. The *<hexadecimal digits>* string must be enclosed in single quotes (').

#### **B or b**

Specifies binary digits. The *<binary digits>* string must be enclosed in single quotes (').

Examples

```
=> SELECT X'abcd';
?column?
```

```

\253\315
(1 row)
```

```
=> SELECT B'101100';
?column?
```

```

,
(1 row)
```

## Extended string literals

### Syntax

```
E'characters'
```

### Parameters

#### **characters**

Arbitrary sequence of characters bounded by single quotes (') You can use C-style backslash sequence in extended string literals, which are an extension to the SQL standard. You specify an extended string literal by writing the letter E as a prefix (before the opening single quote); for example:

```
E'extended character string\n'
```

Within an extended string, the backslash character ( \ ) starts a C-style backslash sequence, in which the combination of backslash and following character or numbers represent a special byte value, as shown in the following list. Any other character following a backslash is taken literally; for example, to include a backslash character, write two backslashes ( \\ ).

- \\ is a backslash
- \b is a backspace
- \f is a form feed
- \n is a newline
- \r is a carriage return
- \t is a tab
- \x##, where ## is a 1 or 2-digit hexadecimal number; for example \x07 is a tab
- \###, where ### is a 1, 2, or 3-digit octal number representing a byte with the corresponding code.

When an extended string literal is concatenated across lines, write only E before the first opening quote:

```
=> SELECT E'first part o'
' a long line';
?column?
```

```

first part of a long line
(1 row)
```

Two adjacent single quotes are used as one single quote:

```
=> SELECT 'Aren"t string literals fun?';
?column?
```

```

Aren't string literals fun?
(1 row)
```

## Standard conforming strings and escape characters

When interpreting commands, such as those entered in [vsq](#) or in queries passed via JDBC or ODBC, Vertica uses standard conforming strings as specified in the SQL standard. In standard conforming strings, backslashes are treated as string literals (ordinary characters), not escape characters.

### Note

Text read in from files or streams (such as the data inserted using the [COPY](#) statement) are not treated as literal strings. The COPY command defines its own escape characters for the data it reads. See the [COPY](#) statement documentation for details.

The following options are available, but Vertica recommends that you migrate your application to use standard conforming strings at your earliest convenience, after warnings have been addressed.

- To treat back slashes as escape characters, set configuration parameter [StandardConformingStrings](#) to 0.
- To enable standard conforming strings permanently, set the [StandardConformingStrings](#) parameter to '1', as described [below](#).
- To enable standard conforming strings per session, use [SET STANDARD\\_CONFORMING\\_STRING TO ON](#), which treats backslashes as escape characters for the current session only.

Identifying strings that are not standard conforming

The following procedure can be used to identify nonstandard conforming strings in your application so that you can convert them into standard conforming strings:

1. Be sure the [StandardConformingStrings](#) parameter is off, as described in [Internationalization parameters](#).

```
=> ALTER DATABASE DEFAULT SET StandardConformingStrings = 0;
```

#### Note

Vertica recommends that you migrate your application to use standard conforming strings .

2. If necessary, turn on the [EscapeStringWarning](#) parameter.

```
=> ALTER DATABASE DEFAULT SET EscapeStringWarning = 1;
```

Vertica now returns a warning each time it encounters an escape string within a string literal. For example, Vertica interprets the `\n` in the following example as a new line:

```
=> SELECT 'a\nb';
WARNING: nonstandard use of escape in a string literal at character 8
HINT: Use the escape string syntax for escapes, e.g., E'\n'.
?column?

a
b
(1 row)
```

When [StandardConformingStrings](#) is **ON** , the string is interpreted as four characters: `a \ n b` .

Modify each string that Vertica flags by extending it as in the following example:

```
E'a\nb'
```

Or if the string has quoted single quotes, double them; for example, `'one" double'`.

3. Turn on the [StandardConformingStrings](#) parameter for all sessions:

```
=> ALTER DATABASE DEFAULT SET StandardConformingStrings = 1;
```

Doubled single quotes

This section discusses vsql inputs that are not passed on to the server. Vertica recognizes two consecutive single quotes within a string literal as one single quote character. For example, the following inputs, `'You"re here!` ignored the second consecutive quote and returns the following:

```
=> SELECT 'You"re here!';
?column?

You're here!at
(1 row)
```

This is the SQL standard representation and is preferred over the form, `'You\re here!` , because backslashes are not parsed as before. You need to escape the backslash:

```
=> SELECT (E'You\re here!');
?column?

You're here!
(1 row)
```

This behavior change introduces a potential incompatibility in the use of the vsql meta-command `\set`, which automatically concatenates its arguments. For example:

```
\set file \" `pwd` '/file.txt' \"\`echo :file
```

vsql takes the four arguments and outputs the following:

```
'/home/vertica/file.txt'
```

Vertica parses the adjacent single quotes as follows:

```
\set file \"`pwd`/file.txt\"`\`echo :file
'/home/vertica/file.txt'
```

Note the extra single quote at the end. This is due to the pair of adjacent single quotes together with the backslash-quoted single quote.

The extra quote can be resolved either as in the first example above, or by combining the literals as follows:

```
\set file \"`pwd`'/file.txt'\"\`echo :file
'/home/vertica/file.txt'
```

In either case the backslash-quoted single quotes should be changed to doubled single quotes as follows:

```
\set file "" `pwd` '/file.txt'
```

Additional examples

```
=> SELECT 'This \is a string';
?column?
```

```

This \is a string
(1 row)
```

```
=> SELECT E'This \is a string';
?column?
```

```

This is a string
```

```
=> SELECT E'This is a \n new line';
?column?
```

```

This is a
new line
(1 row)
```

```
=> SELECT 'String"s characters';
?column?
```

```

String's characters
(1 row)
```

Date/time literals

Date or time literal input must be enclosed in single quotes. Input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others.

Vertica handles date/time input more flexibly than the SQL standard requires. The exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones are described in [Date/time expressions](#).

In this section

- [Time zone values](#)
- [Day of the week names](#)
- [Month names](#)
- [Interval literal](#)

## Time zone values

Vertica attempts to be compatible with the SQL standard definitions for time zones. However, the SQL standard has an odd mix of date and time types and capabilities. Obvious problems are:

- Although the [DATE](#) type does not have an associated time zone, the [TIME](#) type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
- Vertica assumes your local time zone for any data type containing only date or time.
- The default time zone is specified as a constant numeric offset from UTC. It is therefore not possible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, OpenText recommends using Date/Time types that contain both date and time when you use time zones. OpenText recommends that you do *not* use the type [TIME WITH TIME ZONE](#), even though it is supported for legacy applications and for compliance with the SQL standard.

Time zones and time-zone conventions are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900's, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules.

Vertica currently supports daylight-savings rules over the time period 1902 through 2038, corresponding to the full range of conventional UNIX system time. Times outside that range are taken to be in "standard time" for the selected time zone, no matter what part of the year in which they occur.

Example	Description
<a href="#">PST</a>	Pacific Standard Time
<a href="#">-8:00</a>	ISO-8601 offset for PST
<a href="#">-800</a>	ISO-8601 offset for PST
<a href="#">-8</a>	ISO-8601 offset for PST
<a href="#">zulu</a>	Military abbreviation for UTC
<a href="#">z</a>	Short form of <a href="#">zulu</a>

## Day of the week names

The following tokens are recognized as names of days of the week:

Day	Abbreviations
SUNDAY	SUN
MONDAY	MON
TUESDAY	TUE, TUES
WEDNESDAY	WED, WEDS
THURSDAY	THU, THUR, THURS
FRIDAY	FRI
SATURDAY	SAT

## Month names

The following tokens are recognized as names of months:

Month	Abbreviations
-------	---------------

JANUARY	JAN
FEBRUARY	FEB
MARCH	MAR
APRIL	APR
MAY	MAY
JUNE	JUN
JULY	JUL
AUGUST	AUG
SEPTEMBER	SEP, SEPT
OCTOBER	OCT
NOVEMBER	NOV
DECEMBER	DEC

Interval literal

A literal that represents a time span.

Syntax

```
[@] [-] { quantity subtype-unit }[...][AGO]
```

Parameters

@

Ignored

- (**minus**)

Specifies a negative interval value.

**quantity**

Integer [numeric constant](#)

**subtype-unit**

See [Interval subtype units](#) for valid values. Subtype units must be specified for [year-month](#) intervals; they are optional for [day-time](#) intervals.

**AGO**

Specifies a negative interval value. **AGO** and - (minus) are synonymous.

Notes

- The amounts of different units are implicitly added up with appropriate sign accounting.
- The boundaries of an interval constant are:
  - `9223372036854775807 usec` to `-9223372036854775807 usec`
  - `296533 years 3 mons 21 days 04:00:54.775807` to `-296533 years -3 mons -21 days -04:00:54.775807`
- The range of an interval constant is  $\pm 2^{63} - 1$  microseconds.
- In Vertica, interval fields are additive and accept large floating-point numbers.

Examples

See [Specifying interval input](#).

In this section

- [Interval subtype units](#)
- [Interval qualifier](#)

## Interval subtype units

The following tables lists subtype units that you can specify in an interval literal, divided into major categories:

- [Year-month subtype units](#)
- [Day-time subtype units](#)

### Year-month subtype units

Subtypes	Units	Notes
Millennium	<a href="#">mil</a> , <a href="#">millennium</a> , <a href="#">millennia</a> , <a href="#">mils</a> , <a href="#">millenniums</a>	
Century	<a href="#">c</a> , <a href="#">cent</a> , <a href="#">century</a> , <a href="#">centuries</a>	
Decade	<a href="#">dec</a> , <a href="#">decs</a> , <a href="#">decade</a> , <a href="#">decades</a>	
Year	<a href="#">a</a>	Julian year: 365.25 days
	<a href="#">ka</a>	Julian kilo-year: 365250 days
	<a href="#">y</a> , <a href="#">yr</a> , <a href="#">yrs</a> , <a href="#">year</a> , <a href="#">years</a>	Calendar year: 365 days
Quarter	<a href="#">q</a> , <a href="#">qtr</a> , <a href="#">qtrs</a> , <a href="#">quarter</a> , <a href="#">quarters</a>	
Month	<a href="#">m</a> , <a href="#">mon</a> , <a href="#">mons</a> , <a href="#">months</a> , <a href="#">month</a>	Vertica can interpret <a href="#">m</a> as minute or month, depending on context. See <a href="#">Processing m Input</a> below.
Week	<a href="#">w</a> , <a href="#">wk</a> , <a href="#">week</a> , <a href="#">wks</a> , <a href="#">weeks</a>	

### Day-time subtype units

Subtypes	Units	Notes
Day	<a href="#">d</a> , <a href="#">day</a> , <a href="#">days</a>	
Hour	<a href="#">h</a> , <a href="#">hr</a> , <a href="#">hrs</a> , <a href="#">hour</a> , <a href="#">hours</a>	
Minute	<a href="#">m</a> , <a href="#">min</a> , <a href="#">mins</a> , <a href="#">minute</a> , <a href="#">minutes</a>	Vertica can interpret input unit <a href="#">m</a> as minute or month, depending on context. See <a href="#">Processing m Input</a> below.
Second	<a href="#">s</a> , <a href="#">sec</a> , <a href="#">secs</a> , <a href="#">second</a> , <a href="#">seconds</a>	
Millisecond	<a href="#">ms</a> , <a href="#">msec</a> , <a href="#">msecs</a> , <a href="#">msecond</a> , <a href="#">mseconds</a> , <a href="#">millisecond</a> , <a href="#">milliseconds</a>	
Microsecond	<a href="#">us</a> , <a href="#">usec</a> , <a href="#">usecs</a> , <a href="#">usecond</a> , <a href="#">useconds</a> , <a href="#">microseconds</a> , <a href="#">microsecond</a>	

### Processing m input

Vertica uses context to interpret the input unit [m](#) as months or minutes. For example, the following command creates a one-column table with an interval value:

```
=> CREATE TABLE int_test(i INTERVAL YEAR TO MONTH);
```

Given the following INSERT statement, Vertica interprets the interval literal [1y 6m](#) as 1 year 6 months:

```
=> INSERT INTO int_test VALUES('1y 6m');
```

```
OUTPUT
```

```

 1
(1 row)
=> COMMIT;
COMMIT
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT * FROM int_test;
 i

1 year 6 months
(1 row)
```

### Tip

The [SET INTERVALSTYLE](#) statement changes interval output to include subtype unit identifiers. For details, see [Setting interval unit display](#).

The following [ALTER TABLE](#) statement adds a **DAY TO MINUTE** interval column to table `int_test` :

```
=> ALTER TABLE int_test ADD COLUMN x INTERVAL DAY TO MINUTE;
ALTER TABLE
```

The next INSERT statement sets the first and second columns to 3y 20m and 1y 6m, respectively. In this case, Vertica interprets the **m** input literals in two ways:

- For column `i`, Vertica interprets the **m** input as months, and displays 4 years 8 months.
- For column `x`, Vertica interprets the **m** input as minutes. Because the interval is defined as DAY TO MINUTE, it converts the inserted input value **1y 6m** to 365 days 6 minutes:

```
=> INSERT INTO int_test VALUES ('3y 20m', '1y 6m');
```

```
OUTPUT
```

```

 1
(1 row)
=> SELECT * FROM int_test;
 i | x
-----+-----
1 year 6 months |
4 years 8 months | 365 days 6 mins
(2 rows)
```

### Interval qualifier

Specifies how to interpret and format an [interval literal](#) for output, and optionally sets precision. Interval qualifiers are composed of one or two units:

```
unit [TO unit] [(p)]
```

where:

- *unit* specifies a day-time or year-month [subtype](#).
- *p* specifies precision, an integer between 0 and 6.

### Note

Precision only applies to SECOND units, specifying the number of decimal digits to show after the seconds value decimal point. The default precision for SECOND is 6.

When SECOND is the second unit of a qualifier—for example, DAY TO SECOND or MINUTE TO SECOND—it has a precision of 2 places before the decimal point.

For example:

```
=> SELECT INTERVAL '6 122.538987' MINUTE TO SECOND (5);
?column?

08:02.53899
(1 row)
```

For details, see [Specifying interval precision](#).

If an interval omits an interval qualifier, the default is `DAY TO SECOND(6)`.

Interval qualifiers are divided into two categories:

- [day-time](#)
- [year-month](#)

Day-time interval qualifiers

Qualifier	Description
<code>DAY</code>	Unconstrained
<code>DAY TO HOUR</code>	Span of days and hours
<code>DAY TO MINUTE</code>	Span of days and minutes
<code>DAY TO SECOND [( p )]</code>	Span of days, hours, minutes, seconds, and fractions of a second.
<code>HOUR</code>	Hours within days
<code>HOUR TO MINUTE</code>	Span of hours and minutes
<code>HOUR TO SECOND [( p )]</code>	Span of hours and seconds
<code>MINUTE</code>	Minutes within hours
<code>MINUTE TO SECOND [( p )]</code>	Span of minutes and seconds
<code>SECOND [( p )]</code>	Seconds within minutes

Year-month interval qualifiers

**YEAR**

Unconstrained

**MONTH**

Months within year

**YEAR TO MONTH**

Span of years and months

**Note**

Vertica also supports `INTERVALYM`, which is an alias for `INTERVAL YEAR TO MONTH`. Thus, the following two statements are equivalent:

```
=> SELECT INTERVALYM '1 2';
?column?

1-2
(1 row)
=> SELECT INTERVAL '1 2' YEAR TO MONTH;
?column?

1-2
(1 row)
```

## Examples

See [Controlling interval format](#).

## Operators

Operators are logical, mathematical, and equality symbols used in SQL to evaluate, compare, or calculate values.

In this section

- [Bitwise operators](#)
- [Logical operators](#)
- [Comparison operators](#)
- [Data type coercion operators \(CAST\)](#)
- [Date/time operators](#)
- [Mathematical operators](#)
- [NULL operators](#)
- [String concatenation operators](#)

### Bitwise operators

Bitwise operators perform bit manipulations on INTEGER and BINARY/VARBINARY data types:

Operator	Description	Example	Result
&	AND	12 & 4	4
	OR	32   3	35
#	XOR	17 # 5	20
~	NOT	~1	-2
<< †	Bitwise shift left	1 << 4	16
>> †	Bitwise shift right	8 >> 2	2

† Invalid for BINARY/VARBINARY data types

### String argument handling

String arguments must be explicitly cast as BINARY or VARBINARY data types for all bitwise operators. For example:

```
=> SELECT 'xyz'::VARBINARY & 'zyx'::VARBINARY AS AND;
AND

xyx
(1 row)

=> SELECT 'xyz'::VARBINARY | 'zyx'::VARBINARY AS OR;
OR

zyz
(1 row)
```

Bitwise operators treats all string arguments as equal in length. If the arguments have different lengths, the operator function right-pads the smaller string with one or more zero bytes to equal the length of the larger string.

For example, the following statement ANDs unequal strings `xyz` and `zy`. Vertica right-pads string `zy` with one zero byte. The last character in the result is represented accordingly, as `\000`:

```
=> SELECT 'xyz'::VARBINARY & 'zy'::VARBINARY AS AND;
AND

xy\000
(1 row)
```

### Logical operators

Vertica supports the logical operators AND, OR, and NOT:

- AND evaluates to true when both of the conditions joined by AND are true.
- OR evaluates to true when either condition is true.
- NOT negates the result of any Boolean expression.

AND and OR are commutative—that is, you can switch left and right operands without affecting the result. However, the order of evaluation of sub-expressions is not defined. To force evaluation order, use a [CASE](#) construct.

#### Caution

Do not confuse Boolean operators with the [Boolean predicate](#) or [Boolean](#) data type, which can have only two values: true and false.

### Logic

SQL uses a three-valued Boolean logic where `NULL` represents "unknown":

- `true AND NULL = NULL`
- `true OR NULL = true`
- `false AND NULL = false`
- `false OR NULL = NULL`
- `NULL AND NULL = NULL`
- `NULL OR NULL = NULL`
- `NOT NULL = NULL`

### Comparison operators

Comparison operators are available for all data types where comparison makes sense. All comparison operators are binary operators that return values of true, false, or NULL (unknown).

Operator	Description	Binary function
<	less than	<a href="#">binary_lt</a>

>	greater than	binary_gt
<=	less than or equal to	binary_le
>=	greater than or equal to	binary_ge
= , <=>	equal	binary_eq
<div style="background-color: #e1f5fe; padding: 10px; border: 1px solid #cfe2f3;"> <p><b>Note</b> Do not use the negation operator ( ! ) with the &lt;=&gt; operator. Instead, use != to test for inequality. ! , except as part of != , is the factorial operator.</p> </div>		
!= , <>	not equal (unsupported for correlated subqueries)	binary_ne

### NULL handling

Comparison operators return NULL (unknown) if either or both operands are null. One exception applies: <=> returns true if both operands are NULL, and false if one operand is NULL.

### Collections

When comparing collections, null collections are ordered last. Otherwise, collections are compared element by element until there is a mismatch, and then they are ordered based on the non-matching elements. If all elements are equal up to the length of the shorter one, then the shorter one is ordered first.

### Data type coercion operators (CAST)

Data type coercion (casting) passes an expression value to an input conversion routine for a specified data type, resulting in a constant of the indicated type. In Vertica, data type coercion can be invoked by an explicit cast request that uses one of the following constructs:

#### Syntax

```
SELECT CAST (expression AS data-type)
SELECT expression::data-type
SELECT data-type 'string'
```

#### Parameters

<i>expression</i>	An expression of any type
<i>data-type</i>	An <a href="#">SQL data type</a> that Vertica supports to convert <i>expression</i> .

### Truncation

If a binary value is cast (implicitly or explicitly) to a binary type with a smaller length, the value is silently truncated. For example:

```
=> SELECT 'abcd'::BINARY(2);
?column?

ab
(1 row)
```

Similarly, if a character value is cast (implicitly or explicitly) to a character value with a smaller length, the value is silently truncated. For example:

```
=> SELECT 'abcd'::CHAR(3);
?column?

abc
(1 row)
```

### Binary casting and resizing

Vertica supports only casts and resize operations as follows:

- BINARY to and from VARBINARY
- VARBINARY to and from LONG VARBINARY
- BINARY to and from LONG VARBINARY

On binary data that contains a value with fewer bytes than the target column, values are right-extended with the zero byte '\0' to the full width of the column. Trailing zeros on variable-length binary values are not right-extended:

```
=> SELECT 'ab'::BINARY(4), 'ab'::VARBINARY(4), 'ab'::LONG VARBINARY(4);
?column? | ?column? | ?column?
-----+-----+-----
ab\000\000 | ab | ab
(1 row)
```

#### Automatic coercion

The explicit type cast can be omitted if there is no ambiguity as to the type the constant must be. For example, when a constant is assigned directly to a column, it is automatically coerced to the column's data type.

#### Examples

```
=> SELECT CAST((2 + 2) AS VARCHAR);
?column?

4
(1 row)

=> SELECT (2 + 2)::VARCHAR;
?column?

4
(1 row)

=> SELECT INTEGER '123';
?column?

123
(1 row)

=> SELECT (2 + 2)::LONG VARCHAR
?column?

4
(1 row)

=> SELECT '2.2' + 2;
ERROR: invalid input syntax for integer: "2.2"

=> SELECT FLOAT '2.2' + 2;
?column?

4.2
(1 row)
```

#### See also

- [Data Type Conversions](#)
- [Data Type Coercion Chart](#)
- [CAST Failures](#)

#### In this section

- [Cast failures](#)

#### Cast failures

When you invoke data type coercion (casting) by an explicit cast and the cast fails, the result returns either an error or NULL. Cast failures commonly occur when you try to cast conflicting conversions, such as coercing a VARCHAR expression that contains letters to an integer.

When a cast fails, the result returned depends on the data type.

Data type	Cast failure default
<a href="#">date, time</a>	NULL
literals	error
all other types	error

#### Enabling strict time casts

You can enable all cast failures to result in an error, including those for date/time data types. Doing so lets you see the reason why some or all of the cast failed. To return an error instead of NULL, set the configuration parameter EnableStrictTimeCasts to 1:

```
ALTER SESSION SET EnableStrictTimeCasts=1;
```

By default, EnableStrictTimeCasts is set to 0. Thus, the following attempt to cast a VARCHAR to a TIME data type returns NULL:

```
==> SELECT current_value from configuration_parameters WHERE parameter_name ilike '%EnableStrictTimeCasts%';
current_value

0
(1 row)

=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('one');
INSERT
OUTPUT

1
(1 row)

=> INSERT INTO mytable VALUES('1');
INSERT
OUTPUT

1
(1 row)

=> COMMIT;
COMMIT
=> SELECT a::time FROM mytable;
a

(2 rows)
```

If EnableStrictTimeCasts is enabled, the cast failure returns an error:

```
==> ALTER SESSION SET EnableStrictTimeCasts=1;
ALTER SESSION
=> SELECT a::time FROM mytable;
ERROR 3679: Invalid input syntax for time: "1"
```

#### Returning all cast failures as NULL

To explicitly cast an expression to a requested data type, use the following construct:

```
SELECT expression::data-type
```

Using this command to cast any values to a conflicting data type returns the following error:

```
=> SELECT 'one'::time;
ERROR 3679: Invalid input syntax for time: "one"
```

Vertica also supports the use of the coercion operator `::!`, which is useful when you want to return:

- NULL instead of an error for any non-date/time data types
- NULL instead of an error after setting `EnableStrictTimeCasts`

Returning all cast failures as NULL allows those expressions that succeed during the cast to appear in the result. Those expressions that fail during the cast, however, have a NULL value.

The following example queries `mytable` using the coercion operator `::!`. The query returns NULL where column `a` contains the string `one`, and returns `1` where the column contains `1`. Query results are identical no matter how `EnableStrictTimeCasts` is set:

```
=> SELECT current_value FROM configuration_parameters WHERE parameter_name ilike '%EnableStrictTimeCasts%';
current_value

0
(1 row)

=> SELECT a::int FROM mytable;
a
--
1
(2 rows)

ALTER SESSION SET EnableStrictTimeCasts=1;
ALTER SESSION
=> SELECT a::int FROM mytable;
a
--
1
(2 rows)
```

You can use `::!` for casts of arrays and sets. The cast resolves each element individually, producing NULL for elements that cannot be cast.

Note that this functionality only applies to table data. It does not work on inline constant casts and in expressions automatically reduced to such. For example,

```
SELECT constant ::!float from (select 'some string' as constant) a;
```

results in **ERROR 2826: Could not convert "some string" to a float8**. However, the following returns cast failures as NULL as described:

```
SELECT string_field ::!float FROM (SELECT 'a string' as string_field UNION ALL SELECT 'another string') a;
```

## Date/time operators

Vertica supports usage of arithmetic operators on DATE/TIME operands:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- `/` (division)

## Examples

The operators described below that take `TIME` or `TIMESTAMP` input have two variants:

- Operators that take `TIME WITH TIME ZONE` or `TIMESTAMP WITH TIME ZONE` input.

- Operators that take **TIME WITHOUT TIME ZONE** or **TIMESTAMP WITHOUT TIME ZONE** input.

For brevity, these variants are not shown separately.

The **+** and **\*** operators come in commutative pairs—for example, both **DATE + INTEGER** and **INTEGER + DATE** . Only one of each pair is shown.

Example	Result Type	Result
<code>DATE '2001-09-28' + INTEGER '7'</code>	DATE	'2001-10-05'
<code>DATE '2001-09-28' + INTERVAL '1 HOUR'</code>	TIMESTAMP	'2001-09-28 01:00:00'
<code>DATE '2001-09-28' + TIME '03:00'</code>	TIMESTAMP	'2001-09-28 03:00:00'
<code>INTERVAL '1 DAY' + INTERVAL '1 HOUR'</code>	INTERVAL	'1 DAY 01:00:00'
<code>TIMESTAMP '2001-09-28 01:00' + INTERVAL '23 HOURS'</code>	TIMESTAMP	'2001-09-29 00:00:00'
<code>TIME '01:00' + INTERVAL '3 HOURS'</code>	TIME	'04:00:00'
<code>- INTERVAL '23 HOURS'</code>	INTERVAL	'-23:00:00'
<code>DATE '2001-10-01' - DATE '2001-09-28'</code>	INTEGER	'3'
<code>DATE '2001-10-01' - INTEGER '7'</code>	DATE	'2001-09-24'
<code>DATE '2001-09-28' - INTERVAL '1 HOUR'</code>	TIMESTAMP	'2001-09-27 23:00:00'
<code>TIME '05:00' - TIME '03:00'</code>	INTERVAL	'02:00:00'
<code>TIME '05:00' - INTERVAL '2 HOURS'</code>	TIME	'03:00:00'
<code>TIMESTAMP '2001-09-28 23:00' - INTERVAL '23 HOURS'</code>	TIMESTAMP	'2001-09-28 00:00:00'
<code>INTERVAL '1 DAY' - INTERVAL '1 HOUR'</code>	INTERVAL	'1 DAY -01:00:00'
<code>TIMESTAMP '2001-09-29 03:00' - TIMESTAMP '2001-09-27 12:00'</code>	INTERVAL	'1 DAY 15:00:00'
<code>900 * INTERVAL '1 SECOND'</code>	INTERVAL	'00:15:00'
<code>21 * INTERVAL '1 DAY'</code>	INTERVAL	'21 DAYS'

DOUBLE PRECISION '3.5' * INTERVAL '1 HOUR'	INTERVAL	'03:30:00'
INTERVAL '1 HOUR' / DOUBLE PRECISION '1.5'	INTERVAL	'00:40:00'

### Mathematical operators

Mathematical operators are provided for many data types.

Operator	Description	Example	Result
!	Factorial	5 !	120
+	Addition	2 + 3	5
-	Subtraction	2 - 3	-1
*	Multiplication	2 * 3	6
/	Division (integer division produces NUMERIC results).	4 / 2	2.00...
//	With integer division, returns an INTEGER rather than a NUMERIC.	117.32 // 2.5	46
%	Modulo (remainder). For details, see <a href="#">MOD</a> .	5 % 4	1
^	Exponentiation	2.0 ^ 3.0	8
/	Square root	/ 25.0	5
/	Cube root	/ 27.0	3
!!	Factorial (prefix operator)	!! 5	120
@	Absolute value	@ -5.0	5

### Factorial operator support

Vertica supports use of factorial operators on positive and negative floating point ( [DOUBLE PRECISION](#) ) numbers and integers. For example:

```
=> SELECT 4.98!;
?column?

115.978600750905
(1 row)
```

Factorial is defined in terms of the gamma function, where (-1) = Infinity and the other negative integers are undefined. For example:

```
(-4)! = NaN
-(4!) = -24
```

Factorial is defined as follows for all complex numbers  $z$  :

```
z! = gamma(z+1)
```

For details, see [Abramowitz and Stegun: Handbook of Mathematical Functions](#).

### NULL operators

To check whether a value is or is not NULL, use the following equivalent constructs:

Standard:

```
[expression IS NULL | expression IS NOT NULL]
```

Non-standard:

```
[expression ISNULL | expression NOTNULL]
```

Do not write `expression = NULL` : NULL represents an unknown value, and two unknown values are not necessarily equal. This behavior conforms to the SQL standard.

#### Note

Some applications might expect that `expression = NULL` returns true if `expression` evaluates to NULL. In this case, modify the application to comply with the SQL standard.

String concatenation operators

To concatenate two strings on a single line, use the concatenation operator (two consecutive vertical bars).

Syntax

```
string || string
```

Parameters

*string*

Expression of type **CHAR** or **VARCHAR**

Notes

- `||` is used to concatenate expressions and constants. The expressions are cast to **VARCHAR** if possible, otherwise to **VARBINARY** , and must both be one or the other.
- Two consecutive strings within a single SQL statement on separate lines are automatically concatenated

Examples

The following example is a single string written on two lines:

```
=> SELECT E'xx' -> '\';
?column?

xx\
(1 row)
```

The following examples show two strings concatenated:

```

=> SELECT E'xx' ||-> '\';
?column?

xx\\
(1 row)

=> SELECT 'auto' || 'mobile';
?column?

automobile
(1 row)

=> SELECT 'auto'-> 'mobile';
?column?

automobile
(1 row)

=> SELECT 1 || 2;
?column?

12
(1 row)

=> SELECT '1' || '2';
?column?

12
(1 row)

=> SELECT '1'-> '2';
?column?

12
(1 row)

```

## Expressions

SQL expressions are the components of a query that compare a value or values against other values. They can also perform calculations. An expression found inside a SQL statement is usually in the form of a conditional statement.

Some functions also use [Lambda functions](#).

## Operator precedence

The following table shows operator precedence in decreasing (high to low) order.

When an expression includes more than one operator, specify the order of operation using parentheses, rather than relying on operator precedence.

Operator/Element	Associativity	Description
.	left	table/column name separator
::	left	typecast
[]	left	array element selection
-	right	unary minus
^	left	exponentiation

* / %	left	multiplication, division, modulo
+ -	left	addition, subtraction
IS		IS TRUE, IS FALSE, IS UNKNOWN, IS NULL
IN		set membership
BETWEEN		range containment
OVERLAPS		time interval overlap
LIKE		string pattern matching
< >		less than, greater than
=	right	equality, assignment
NOT	right	logical negation
AND	left	logical conjunction
OR	left	logical disjunction

#### Expression evaluation rules

The order of evaluation of subexpressions is not defined. In particular, the inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order. To force evaluation in a specific order, use a [CASE](#) construct. For example, this is an untrustworthy way of trying to avoid division by zero in a WHERE clause:

```
=> SELECT x, y WHERE x <> 0 AND y/x > 1.5; --- unsafe
```

But this is safe:

```
=> SELECT x, y
WHERE
CASE
WHEN x <> 0 THEN y/x > 1.5
ELSE false
END;
```

A CASE construct used in this fashion defeats optimization attempts, so use it only when necessary. (In this particular example, it would be best to avoid the issue by writing  $y > 1.5 * x$  instead.)

#### Limits to SQL expressions

Expressions are limited by the available stack. Vertica requires at least 100KB of free stack. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" might be thrown. Adding physical memory and/or increasing the value of `ulimit -s` can increase the available stack and prevent the error.

Analytic expressions have a maximum recursion depth of 2000. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" might be thrown. This limit cannot be increased.

In this section

- [Aggregate expressions](#)
- [CASE expressions](#)
- [Column references](#)
- [Comments](#)
- [Date/time expressions](#)
- [NULL value](#)

#### Aggregate expressions

An aggregate expression applies an aggregate function across the rows or groups of rows selected by a query.

An aggregate expression only can appear in the select list or **HAVING** clause of a **SELECT** statement. It is invalid in other clauses such as **WHERE** , because those clauses are evaluated before the results of aggregates are formed.

#### Syntax

An aggregate expression has the following format:

```
aggregate-function ([*] [ALL | DISTINCT] expression)
```

#### Parameters

<i>aggregate-function</i>	A Vertica function that aggregates data over groups of rows from a query result set.
<b>ALL   DISTINCT</b>	Specifies which input rows to process: <ul style="list-style-type: none"><li>• <b>ALL</b> (default): Invokes <i>aggregate-function</i> across all input rows where <i>expression</i> evaluates to a non-null value.</li><li>• <b>DISTINCT</b> : Invokes <i>aggregate-function</i> across all input rows where <i>expression</i> evaluates to a unique non-null value.</li></ul>
<i>expression</i>	A value expression that does not itself contain an aggregate expression.

#### Examples

The AVG aggregate function returns the average income from the customer\_dimension table:

```
=> SELECT AVG(annual_income) FROM customer_dimension;
AVG

2104270.6485
(1 row)
```

The following example shows how to use the COUNT aggregate function with the DISTINCT keyword to return all distinct values of evaluating the expression x+y for all inventory\_fact records.

```
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
COUNT

21560
(1 row)
```

#### CASE expressions

The **CASE** expression is a generic conditional expression that can be used wherever an expression is valid. It is similar to **CASE** and **IF/THEN/ELSE** statements in other languages.

#### Syntax (form 1)

```
CASE
 WHEN condition THEN result
 [WHEN condition THEN result]
 ...
 [ELSE result]
END
```

#### Parameters

<i>condition</i>	An expression that returns a Boolean (true/false) result. If the condition evaluates to <b>FALSE</b> or <b>NULL</b> , subsequent <b>WHEN</b> clauses are evaluated in the same way.
<i>result</i>	Specifies the value to return when the associated <i>condition</i> is true.
<b>ELSE result</b>	If no <i>condition</i> is true then the value of the <b>CASE</b> expression is the result in the <b>ELSE</b> clause. If the <b>ELSE</b> clause is omitted and no condition matches, the result is NULL.

## Syntax (form 2)

```
CASE expression
WHEN value THEN result
[WHEN value THEN result]
...
[ELSE result]
END
```

## Parameters

<i>expression</i>	An expression that is evaluated and compared to all the <i>value</i> specifications in <b>WHEN</b> clauses until one is found that is equal.
<i>value</i>	Specifies a value to compare to the <i>expression</i> .
<i>result</i>	Specifies the value to return when the <i>expression</i> is equal to the specified <i>value</i> .
<b>ELSE result</b>	Specifies the value to return when the <i>expression</i> is not equal to any <i>value</i> ; if no <b>ELSE</b> clause is specified, the value returned is null.

## Notes

The data types of all result expressions must be convertible to a single output type.

## Examples

The following examples show two uses of the **CASE** statement.

```
=> SELECT * FROM test;
a

1
2
3
=> SELECT a,
 CASE WHEN a=1 THEN 'one'
 WHEN a=2 THEN 'two'
 ELSE 'other'
 END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other
=> SELECT a,
 CASE a WHEN 1 THEN 'one'
 WHEN 2 THEN 'two'
 ELSE 'other'
 END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other
```

## Special example

A **CASE** expression does not evaluate subexpressions that are not needed to determine the result. You can use this behavior to avoid division-by-zero errors:

```
=> SELECT x FROM T1 WHERE
 CASE WHEN x <> 0 THEN y/x > 1.5
 ELSE false
END;
```

## Column references

### Syntax

```
[[[database.]schema.]table-name.]column-name
```

### Parameters

<i>schema</i>	Database and <a href="#">schema</a> . The default schema is <a href="#">public</a> . If you specify a database, it must be the current database.
<i>table-name</i>	One of the following: <ul style="list-style-type: none"><li>• Name of a table</li><li>• Table alias defined in the query's <a href="#">FROM</a> clause</li></ul>
<i>column-name</i>	A column name that is unique among all queried tables.

### Restrictions

A column reference cannot contain any spaces.

### Comments

A comment is an arbitrary sequence of characters beginning with two consecutive hyphen characters and extending to the end of the line. For example:

```
-- This is a standard SQL comment
```

A comment is removed from the input stream before further syntax analysis and is effectively replaced by white space.

Alternatively, C-style block comments can be used where the comment begins with */\** and extends to the matching occurrence of *\*/* .

```
/* multiline comment
 * with nesting: /* nested block comment */
 */
```

These block comments nest, as specified in the SQL standard. Unlike C, you can comment out larger blocks of code that might contain existing block comments.

### Date/time expressions

Vertica uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information might be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

Vertica parses date/time type inputs as follows:

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
2. Numeric token contains:
  - colon (:) — Parse as a time string, include all subsequent digits and colons.
  - dash (-), slash (/), or two or more dots (.) — Parse as a date string which might have a text month.
  - Numeric only — Parse as a single field or an ISO 8601 concatenated date (19990113 for January 13, 1999) or time (141516 for 14:15:16).
3. Token starts with a plus (+) or minus (-): Parse as a time zone or a special field.
4. Token is a text string: match up with possible strings.
  - Perform a binary-search table lookup for the token as either a special string (for example, today), day (for example, Thursday), month (for example, January), or noise word (for example, at, on).
  - Set field values and bit mask for fields. For example, set year, month, day for today, and additionally hour, minute, second for now.
  - If not found, do a similar binary-search table lookup to match the token with a time zone.
  - If still not found, throw an error.
5. Token is a number or number field:
  - If eight or six digits, and if no other date fields were previously read, interpret as a "concatenated date" (19990118 or 990118). The interpretation is [YYYYMMDD](#) or [YYMMDD](#) .
  - If token is three digits and a year was already read, interpret as day of year.
  - If four or six digits and a year was already read, interpret as a time ( [HHMM](#) or [HHMMSS](#) ).

- If three or more digits and no date fields were found yet, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
  - Otherwise the date field ordering is assumed to follow the [DateStyle](#) setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.
6. If BC is specified: negate the year and add one for internal storage. (In the Vertica implementation, 1 BC = year zero.)
  7. If BC is not specified, and year field is two digits in length: adjust the year to four digits. If field is less than 70, add 2000, otherwise add 1900.

### Tip

Gregorian years AD 1–99 can be entered as 4 digits with leading zeros— for example, 0099 = AD 99.

### Month day year ordering

For some formats, ordering of month, day, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields.

### Special date/time values

Vertica supports several special date/time values for convenience, as shown below. All of these values need to be written in single quotes when used as constants in SQL statements.

The values [INFINITY](#) and [-INFINITY](#) are specially represented inside the system and are displayed the same way. The others are simply notational shorthands that are converted to ordinary date/time values when read. (In particular, [NOW](#) and related strings are converted to a specific time value as soon as they are read.)

String	Valid Data Types	Description
<a href="#">epoch</a>	<code>DATE</code> , <code>TIMESTAMP</code>	1970-01-01 00:00:00+00 (UNIX SYSTEM TIME ZERO)
<a href="#">INFINITY</a>	<code>TIMESTAMP</code>	Later than all other time stamps
<a href="#">-INFINITY</a>	<code>TIMESTAMP</code>	Earlier than all other time stamps
<a href="#">NOW</a>	<code>DATE</code> , <code>TIME</code> , <code>TIMESTAMP</code>	Current transaction's start time <b>Note:</b> <a href="#">NOW</a> is not the same as the <a href="#">NOW</a> function.
<a href="#">TODAY</a>	<code>DATE</code> , <code>TIMESTAMP</code>	Midnight today
<a href="#">TOMORROW</a>	<code>DATE</code> , <code>TIMESTAMP</code>	Midnight tomorrow
<a href="#">YESTERDAY</a>	<code>DATE</code> , <code>TIMESTAMP</code>	Midnight yesterday
<a href="#">ALLBALLS</a>	<code>TIME</code>	00:00:00.00 UTC

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type:

- [CURRENT\\_DATE](#)
- [CURRENT\\_TIME](#)
- [CURRENT\\_TIMESTAMP](#)
- [LOCALTIME](#)
- [LOCALTIMESTAMP](#)

The latter four accept an optional precision specification. (See [Date/time functions](#).) However, these functions are SQL functions and are not recognized as data input strings.

### NULL value

NULL is a reserved keyword used to indicate that a data value is unknown. It is the ASCII abbreviation for NULL characters (`\0`).

### Usage in expressions

Vertica does not treat an empty string as a NULL value. An expression must specify NULL to indicate that a column value is unknown.

The following considerations apply to using NULL in expressions:

- NULL is not greater than, less than, equal to, or not equal to any other expression. Use the [Boolean](#) to determine whether an expression value is NULL.
- You can write queries with expressions that contain the `<=>` operator for `NULL=NULL` joins. See [Equi-joins and non equi-joins](#).
- Vertica accepts NULL characters ( `'\0'` ) in constant strings and does not remove null characters from VARCHAR fields on input or output.

Projection ordering of NULL data

Vertica sorts NULL values in projection columns as follows:

Column data type	NULL values placed at...
<a href="#">NUMERIC INTEGER DATE TIME TIMESTAMP INTERVAL</a>	Beginning of sorted column ( <b>NULLS FIRST</b> )
<a href="#">FLOAT STRING BOOLEAN</a>	End of sorted column ( <b>NULLS LAST</b> )

See also

[NULL-handling functions](#)

Lambda functions

Some SQL functions have arguments that are lambda functions. A lambda function is an unnamed inline function that is evaluated by the containing SQL function and returns a value.

Syntax

Lambda with one argument:

```
argument -> expression
```

Lambda with more than one argument:

```
(argument, ...) -> expression
```

Arguments

<i>argument</i>	Name to use for an input value for the expression. The name cannot be a reserved keyword, the name of an argument to a parent or nested lambda, or a column name or alias.
<i>expression</i>	Expression that uses the input arguments and returns a result to the containing SQL function. See the documentation of individual SQL functions for restrictions on return values. For example, some functions require a Boolean result.

Examples

The [ARRAY\\_FIND](#) function returns the first index that matches the element being searched for. Instead of a literal element, you can write a lambda function that returns a Boolean. The lambda function is applied to each element in the array until a match is found or all elements have been tested. In the following example, each person in the table has an array of email addresses, and the function locates fake addresses:

```
=> CREATE TABLE people (id INT, name VARCHAR, email ARRAY[VARCHAR,5]);
```

```
=> SELECT name, ARRAY_FIND(email, e -> REGEXP_LIKE(e,'example.com','i'))
```

```
AS 'example.com'
```

```
FROM people;
```

```
name | example.com
```

```
-----+-----
```

```
Alice Adams | 1
```

```
Bob Adams | 1
```

```
Carol Collins | 0
```

```
Dave Jones | 0
```

```
(4 rows)
```

The argument `e` represents the individual element, and the body of the lambda expression is the regular-expression comparison. The input table has four rows; in each row, the lambda function is called once per array element.

In the following example, a `schedules` table includes an array of events, where each event is a ROW with several fields:

```
=> CREATE TABLE schedules
 (guest VARCHAR,
 events ARRAY[ROW(e_date DATE, e_name VARCHAR, price NUMERIC(8,2))]);
```

You can use the [CONTAINS](#) function with a lambda expression to find people who have more than one event on the same day. The second argument, `idx`, is the index of the current element:

```
=> SELECT guest FROM schedules
WHERE CONTAINS(events, (e, idx) ->
 (idx < ARRAY_LENGTH(events) - 1
 AND (e.e_date = events[idx + 1].e_date));
 guest

Alice Adams
(1 row)
```

## Predicates

Predicates are truth-tests. If the predicate test is true, it returns a value. Each predicate is evaluated per row, so that when the predicate is part of an entire table SELECT statement, the statement can return multiple results.

Predicates consist of a set of parameters and arguments. For example, in the following WHERE clause:

```
WHERE name = 'Smith'
```

- `name = 'Smith'` is the predicate
- `'Smith'` is an expression

In this section

- [ANY and ALL](#)
- [BETWEEN](#)
- [Boolean](#)
- [EXISTS](#)
- [IN](#)
- [INTERPOLATE](#)
- [LIKE](#)
- [NULL](#)

## ANY and ALL

ANY and ALL are logical operators that let you make comparisons on subqueries that return one or more rows. Both operators must be preceded by a [comparison operator](#) and followed by a subquery:

```
expression comparison-operator { ANY | ALL } (subquery)
```

- ANY returns true if the comparison between *expression* and any value returned by *subquery* evaluates to true.
- ALL returns true only if the comparison between *expression* and all values returned by *subquery* evaluates to true.

## Equivalent operators

You can use the following operators instead of ANY or ALL:

This operator...	Is equivalent to:
SOME	ANY
IN	= ANY
NOT IN	<> ALL

## NULL handling

Vertica supports multicolumn <> ALL subqueries where the columns are not marked **NOT NULL**. If any column contains a NULL value, Vertica returns a run-time error.

Vertica does not support ANY subqueries that are nested in another expression if any column values are NULL.

## Examples

Examples below use the following tables and data:

```
-> SELECT * FROM t1 ORDER BY c1;
```

```
c1 | c2
---+----
1 | cab
1 | abc
2 | fed
2 | def
3 | ihg
3 | ghi
4 | jkl
5 | mno
(8 rows)
```

```
-> SELECT * FROM t2 ORDER BY c1;
```

```
c1 | c2
---+----
1 | abc
2 | fed
3 | jkl
3 | stu
3 | zzz
(5 rows)
```

## ANY subqueries

Subqueries that use the ANY keyword return true when any value retrieved in the subquery matches the value of the left-hand expression.

ANY subquery within an expression:

```
-> SELECT c1, c2 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)));
```

```
c1 | c2
---+----
2 | fed
2 | def
3 | ihg
3 | ghi
4 | jkl
5 | mno
(6 rows)
```

ANY noncorrelated subqueries without aggregates:

```
-> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
```

```
c1
--
1
1
2
2
3
3
(6 rows)
```

ANY noncorrelated subqueries with aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1 | c2
---+---
1 | cab
1 | abc
2 | fed
2 | def
4 | jkl
5 | mno
(6 rows)
```

```
=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1

1
2
4
5
(4 rows)
```

ANY noncorrelated subqueries with aggregates and a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
```

```
c1 | c2
---+---
1 | cab
1 | abc
2 | fed
2 | def
3 | ihg
3 | ghi
4 | jkl
5 | mno
(8 rows)
```

ANY noncorrelated subqueries with a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <=> ANY (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
```

```
c1 | c2
---+---
1 | cab
1 | abc
2 | fed
2 | def
3 | ihg
3 | ghi
(6 rows)
```

ANY correlated subqueries with no aggregates or GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 >= ANY (SELECT c1 FROM t2 WHERE t2.c2 = t1.c2) ORDER BY c1;
```

```
c1 | c2
---+---
1 | abc
2 | fed
4 | jkl
(3 rows)
```

ALL subqueries

A subquery that uses the ALL keyword returns true when all values retrieved by the subquery match the left-hand expression, otherwise it returns false.

ALL noncorrelated subqueries without aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 >= ALL (SELECT c1 FROM t2) ORDER BY c1;
```

```
c1 | c2

3 | ihg
3 | ghi
4 | jkl
5 | mno
(4 rows)
```

ALL noncorrelated subqueries with aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 = ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1 | c2

3 | ihg
3 | ghi
(2 rows)
```

```
=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
```

```
c1
--
1
2
4
5
(4 rows)
```

ALL noncorrelated subqueries with aggregates and a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <= ALL (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
```

```
c1 | c2

1 | cab
1 | abc
(2 rows)
```

ALL noncorrelated subqueries with a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ALL (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
```

```
c1 | c2

4 | jkl
5 | mno
(2 rows)
```

## BETWEEN

Checks whether an expression is within the range of two other expressions, inclusive. All expressions must be of the same or compatible data types.

### Syntax

```
WHERE a BETWEEN x AND y
```

### Equivalent predicates

The following BETWEEN predicates can be rewritten in conventional SQL with logical operators AND and OR.

This BETWEEN predicate...	Is equivalent to...
WHERE a BETWEEN x AND y	WHERE a >= x AND a <= y
WHERE a NOT BETWEEN x AND y	WHERE a < x OR a > y

### Examples

The BETWEEN predicate can be especially useful for querying date ranges, as shown in the following examples:

```
=> SELECT NOW()::DATE;
 NOW

2022-12-15
(1 row)

=> CREATE TABLE t1 (a INT, b varchar(12), c DATE);
CREATE TABLE
=> INSERT INTO t1 VALUES
 (0,'today',NOW()),
 (1,'today+1',NOW()+1),
 (2,'today+2',NOW()+2),
 (3,'today+3',NOW()+3),
 (4,'today+4',NOW()+4),
 (5,'today+5',NOW()+5),
 (6,'today+6',NOW()+6);
OUTPUT

 7
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM t1;
 a | b | c
---+-----+-----
 0 | today | 2022-12-15
 1 | today+1 | 2022-12-16
 2 | today+2 | 2022-12-17
 3 | today+3 | 2022-12-18
 4 | today+4 | 2022-12-19
 5 | today+5 | 2022-12-20
 6 | today+6 | 2022-12-21
(7 rows)

=> SELECT * FROM t1 WHERE c BETWEEN '2022-12-17' AND '2022-12-20';
 a | b | c
---+-----+-----
 2 | today+2 | 2022-12-17
 3 | today+3 | 2022-12-18
 4 | today+4 | 2022-12-19
 5 | today+5 | 2022-12-20
(4 rows)
```

Use the NOW and INTERVAL keywords to query a date range:

```
=> SELECT * FROM t1 WHERE c BETWEEN NOW()::DATE AND NOW()::DATE + INTERVAL '2 days';
 a | b | c
---+-----+-----
 0 | today | 2022-12-15
 1 | today+1 | 2022-12-16
 2 | today+2 | 2022-12-17
(3 rows)
```

Boolean

Retrieves rows where the value of an expression is true, false, or unknown (NULL).

Syntax

```
expression IS [NOT] TRUE
expression IS [NOT] FALSE
expression IS [NOT] UNKNOWN
```

## Notes

- NULL input is treated as the value **UNKNOWN**.
- **IS UNKNOWN** and **IS NOT UNKNOWN** are effectively the same as the [NULL predicate](#), except that the input expression does not have to be a single column value. To check a single column value for NULL, use the NULL predicate.
- Do not confuse the Boolean predicate with [Boolean operators](#) or the [Boolean](#) data type, which can have only two values: true and false.

## EXISTS

EXISTS and NOT EXISTS predicates compare an expression against a subquery:

- EXISTS returns true if the subquery returns one or more rows.
- NOT EXISTS returns true if the subquery returns no rows.

## Syntax

```
expression [NOT] EXISTS (subquery)
```

## Usage

EXISTS results only depend on whether any or no records are returned, and not on the contents of those records. Because the subquery output is usually of no interest, EXISTS tests are commonly written in one of the following ways:

```
EXISTS (SELECT 1 WHERE...)
```

```
EXISTS (SELECT * WHERE...)
```

In the first case, the subquery returns 1 for every record found by the subquery. For example, the following query retrieves a list of all customers whose store purchases were greater than 550 dollars:

```
-> SELECT customer_key, customer_name, customer_state
FROM public.customer_dimension WHERE EXISTS
 (SELECT 1 FROM store.store_sales_fact
 WHERE customer_key = public.customer_dimension.customer_key
 AND sales_dollar_amount > 550)
AND customer_state = 'MA' ORDER BY customer_key;
customer_key | customer_name | customer_state

2 | Anna G. Li | CA
4 | Daniel I. Fortin | TX
7 | David H. Greenwood | MA
8 | Wendy S. Young | IL
9 | Theodore X. Brown | MA
...
49902 | Amy O. Pavlov | MA
49922 | Doug C. Carcetti | MA
49930 | Theodore G. McNulty | MA
49979 | Ben Z. Miller | MA
(1058 rows)
```

## EXISTS versus IN

Whether you use EXISTS or IN subqueries depends on which predicates you select in outer and inner query blocks. For example, the following query gets a list of all the orders placed by all stores on January 2, 2007 for vendors with records in the vendor table:

```

=> SELECT store_key, order_number, date_ordered
 FROM store.store_orders_fact WHERE EXISTS
 (SELECT 1 FROM public.vendor_dimension vd JOIN store.store_orders_fact ord ON vd.vendor_key = ord.vendor_key)
 AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered
-----+-----+-----
 114 | 271071 | 2007-01-02
 19 | 290888 | 2007-01-02
 132 | 58942 | 2007-01-02
 232 | 9286 | 2007-01-02
 126 | 224474 | 2007-01-02
 196 | 63482 | 2007-01-02
 ...
 196 | 83327 | 2007-01-02
 138 | 278373 | 2007-01-02
 179 | 293586 | 2007-01-02
 155 | 213413 | 2007-01-02
(506 rows)

```

The above query looks for existence of the vendor and date ordered. To return a particular value, rather than simple existence, the query looks for orders placed by the vendor who got the best deal on January 2, 2007:

```

=> SELECT store_key, order_number, date_ordered, vendor_name
 FROM store.store_orders_fact ord JOIN public.vendor_dimension vd ON ord.vendor_key = vd.vendor_key
 WHERE vd.deal_size IN (SELECT MAX(deal_size) FROM public.vendor_dimension) AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered | vendor_name
-----+-----+-----+-----
 50 | 99234 | 2007-01-02 | Everything Wholesale
 81 | 200802 | 2007-01-02 | Everything Wholesale
 115 | 13793 | 2007-01-02 | Everything Wholesale
 204 | 41842 | 2007-01-02 | Everything Wholesale
 133 | 169025 | 2007-01-02 | Everything Wholesale
 163 | 208580 | 2007-01-02 | Everything Wholesale
 29 | 154972 | 2007-01-02 | Everything Wholesale
 145 | 236790 | 2007-01-02 | Everything Wholesale
 249 | 54838 | 2007-01-02 | Everything Wholesale
 7 | 161536 | 2007-01-02 | Everything Wholesale
(10 rows)

```

See also

[IN](#)  
IN

Checks whether a single value is found (or not found) within a set of values.

Syntax

```
(column-list) [NOT] IN (values-list)
```

Arguments

**column-list**

One or more comma-delimited columns in the queried tables.

**values-list**

Comma-delimited list of constant values to find in the *column-list* columns. Each *values-list* value maps to a *column-list* column according to their order in *values-list* and *column-list*, respectively. Column/value pairs must have [compatible](#) data types.

You can specify multiple sets of values as follows:

```
((values-list), (values-list) [...])
```

Null handling

Vertica supports multicolumn NOT IN subqueries where the columns are not marked [NOT NULL](#). If one of the columns is found to contain a NULL value during query execution, Vertica returns a run-time error.

Similarly, IN subqueries nested within another expression are not supported if any column values are NULL. For example, if in the following statement column **x** from either table contains a NULL value, Vertica returns a run-time error:

```
-> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;
ERROR: NULL value found in a column used by a subquery
```

## EXISTS versus IN

Whether you use EXISTS or IN subqueries depends on which predicates you select in outer and inner query blocks. For example, the following query gets a list of all the orders placed by all stores on January 2, 2007 for vendors with records in the vendor table:

```
-> SELECT store_key, order_number, date_ordered
FROM store.store_orders_fact WHERE EXISTS
 (SELECT 1 FROM public.vendor_dimension vd JOIN store.store_orders_fact ord ON vd.vendor_key = ord.vendor_key)
AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered
-----+-----+-----
 114 | 271071 | 2007-01-02
 19 | 290888 | 2007-01-02
 132 | 58942 | 2007-01-02
 232 | 9286 | 2007-01-02
 126 | 224474 | 2007-01-02
 196 | 63482 | 2007-01-02
...
 196 | 83327 | 2007-01-02
 138 | 278373 | 2007-01-02
 179 | 293586 | 2007-01-02
 155 | 213413 | 2007-01-02
(506 rows)
```

The above query looks for existence of the vendor and date ordered. To return a particular value, rather than simple existence, the query looks for orders placed by the vendor who got the best deal on January 2, 2007:

```
-> SELECT store_key, order_number, date_ordered, vendor_name
FROM store.store_orders_fact ord JOIN public.vendor_dimension vd ON ord.vendor_key = vd.vendor_key
WHERE vd.deal_size IN (SELECT MAX(deal_size) FROM public.vendor_dimension) AND date_ordered = '2007-01-02';
store_key | order_number | date_ordered | vendor_name
-----+-----+-----+-----
 50 | 99234 | 2007-01-02 | Everything Wholesale
 81 | 200802 | 2007-01-02 | Everything Wholesale
 115 | 13793 | 2007-01-02 | Everything Wholesale
 204 | 41842 | 2007-01-02 | Everything Wholesale
 133 | 169025 | 2007-01-02 | Everything Wholesale
 163 | 208580 | 2007-01-02 | Everything Wholesale
 29 | 154972 | 2007-01-02 | Everything Wholesale
 145 | 236790 | 2007-01-02 | Everything Wholesale
 249 | 54838 | 2007-01-02 | Everything Wholesale
 7 | 161536 | 2007-01-02 | Everything Wholesale
(10 rows)
```

## Examples

The following SELECT statement queries all data in table **t11**.

```

-> SELECT * FROM t11 ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG

1 | 2 | 3 | t
2 | 3 | 4 | t
3 | 4 | 5 | t
4 | 5 | 6 | t
5 | 6 | 7 | t
6 | | 8 | f
7 | 8 | | t
(7 rows)

```

The following query specifies an **IN** predicate, to find all rows in **t11** where columns **col1** and **col2** contain values of **(2,3)** or **(6,7)** :

```

-> SELECT * FROM t11 WHERE (col1, col2) IN ((2,3), (6,7)) ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG

1 | 2 | 3 | t
5 | 6 | 7 | t
(2 rows)

```

The following query uses the [VMart](#) schema to illustrate the use of outer expressions referring to different inner expressions:

```

-> SELECT product_description, product_price FROM product_dimension
WHERE (product_dimension.product_key, product_dimension.product_key) IN
(SELECT store.store_orders_fact.order_number,
store.store_orders_fact.quantity_ordered
FROM store.store_orders_fact);
product_description | product_price

Brand #73 wheelchair | 454
Brand #72 box of candy | 326
Brand #71 vanilla ice cream | 270
(3 rows)

```

## INTERPOLATE

Joins two [event series](#) using some ordered attribute. Event series joins let you compare values from two series directly, rather than having to normalize the series to the same measurement interval.

An event series join is an extension of a regular [outer join](#). The difference between expressing a regular outer join and an event series join is the **INTERPOLATE** predicate, which is used in the **ON** clause (see [Examples](#) below). Instead of padding the non-preserved side with null values when there is no match, the event series join pads the non-preserved side with the previous/next values from the table.

Interpolated values come from the table that contains the null, not from the other table. Vertica does not guarantee that the output contains no null values. If there is no previous/next value for a mismatched row, that row is padded with nulls.

### Syntax

```
expression1 INTERPOLATE { PREVIOUS | NEXT } VALUE expression2
```

### Arguments

*expression1* ,  
*expression2*

A [column reference](#) from one of the tables specified in the [FROM clause](#).

The columns can be of any data type. Because event series are time-based, the type is typically **DATE/TIME** or **TIMESTAMP**.

{ PREVIOUS | NEXT  
} VALUE

Pads the non-preserved side with the previous/next values when there is no match. If previous is called on the first row (or next on the last row), will pad with null values.

Input rows are sorted in ascending logical order of the join column.

#### Note

An ORDER BY clause, if used, does not determine the input order but only determines query output order.

#### Notes

- Data is logically partitioned on the table in which it resides, based on other ON clause equality predicates.
- Event series join requires that the joined tables are both sorted on columns in equality predicates, in any order, followed by the INTERPOLATED column. If data is already sorted in this order, then an explicit sort is avoided, which can improve query performance. For example, given the following tables:

```
ask: exchange, stock, ts, pricebid: exchange,
stock, ts, price
```

In the query that follows:

- `ask` is sorted on `exchange, stock` (or the reverse), `ts`
- `bid` is sorted on `exchange, stock` (or the reverse), `ts`

```
SELECT ask.price - bid.price, ask.ts, ask.stock, ask.exchange
FROM ask FULL OUTER JOIN bid
ON ask.stock = bid.stock AND ask.exchange =
bid.exchange AND ask.ts INTERPOLATE PREVIOUS
VALUE bid.ts;
```

#### Restrictions

- Only one INTERPOLATE expression is allowed per join.
- INTERPOLATE expressions are used only with ANSI SQL-99 syntax (the ON clause), which is already true for full outer joins.
- INTERPOLATE can be used with equality predicates only.
- The AND operator is supported but not the OR and NOT operators.
- Expressions and implicit or explicit casts are not supported, but subqueries are allowed.

#### Semantics

When you write an event series join in place of normal join, values are evaluated as follows (using the schema in the examples below):

- `t` is the outer, preserved table.
- `t1` is the inner, non-preserved table.
- For each row in outer table `t`, the ON clause predicates are evaluated for each combination of each row in the inner table `t1`.
- If the ON clause predicates evaluate to true for any combination of rows, those combination rows are produced at the output.
- If the ON clause is false for all combinations, a single output row is produced with the values of the row from `t` along with the columns of `t1` chosen from the row in `t1` with the greatest `t1.y` value such that `t1.y < t.x`; If no such row is found, pad with nulls.

#### Note

`t LEFT OUTER JOIN t1` is equivalent to `t1 RIGHT OUTER JOIN t`.

In the case of a full outer join, all values from both tables are preserved.

#### Examples

The examples that follow use this simple schema.

```
CREATE TABLE t(x TIME);
CREATE TABLE t1(y TIME);
INSERT INTO t VALUES('12:40:23');
INSERT INTO t VALUES('13:40:25');
INSERT INTO t VALUES('13:45:00');
INSERT INTO t VALUES('14:49:55');
INSERT INTO t1 VALUES('12:40:23');
INSERT INTO t1 VALUES('14:00:00');
COMMIT;
```

Normal full outer join

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x = t1.y;
```

Notice the null rows from the non-preserved table:

```
x | y
-----+-----
12:40:23 | 12:40:23
13:40:25 |
13:45:00 |
14:49:55 |
 | 14:00:00
(5 rows)
```

Full outer join with interpolation

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```

In this case, the rows with no entry point are padded with values from the previous row.

```
x | y
-----+-----
12:40:23 | 12:40:23
13:40:25 | 12:40:23
13:45:00 | 12:40:23
14:49:55 | 12:40:23
13:40:25 | 14:00:00
(5 rows)
```

Likewise, interpolate next is also supported:

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x INTERPOLATE NEXT VALUE t1.y;
```

In this case, the rows with no entry point are padded with values from the next row.

```
x | y
-----+-----
12:40:23 | 12:40:23
13:40:25 | 14:00:00
13:45:00 | 14:00:00
14:49:55 |
14:49:55 | 14:00:00
(5 rows)
```

Normal left outer join

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x = t1.y;
```

Again, there are nulls in the non-preserved table

x	y
12:40:23	12:40:23
13:40:25	
13:45:00	
14:49:55	

(4 rows)

Left outer join with interpolation

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```

Nulls have been padded with interpolated values.

x	y
12:40:23	12:40:23
13:40:25	12:40:23
13:45:00	12:40:23
14:49:55	14:00:00

(4 rows)

Likewise, interpolate next is also supported:

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x INTERPOLATE NEXT VALUE t1.y;
```

Nulls have been padded with interpolated values here as well.

x	y
12:40:23	12:40:23
13:40:25	14:00:00
13:45:00	14:00:00
14:49:55	

(4 rows)

Inner joins

For inner joins, there is no difference between a regular inner join and an event series inner join. Since null values are eliminated from the result set, there is nothing to interpolate.

A regular inner join returns only the single matching row at 12:40:23:

```
=> SELECT * FROM t INNER JOIN t1 ON t.x = t1.y;
```

x	y
12:40:23	12:40:23

(1 row)

An event series inner join finds the same single-matching row at 12:40:23:

```
=> SELECT * FROM t INNER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```

x	y
12:40:23	12:40:23

(1 row)

[Event series joins](#)

In this section

- [Join predicate](#)

Join predicate

Specifies the columns on which records from two or more tables are joined. You can connect multiple join predicates with logical operators **AND**, **OR**, and **NOT**.

## Syntax

```
ON column-ref = column-ref [{AND | OR | NOT } column-ref = column-ref]...
```

## Parameters

[column-ref](#) Specifies a column in a queried table. For best performance, do not join on **LONG VARBINARY** and **LONG VARCHAR** columns.

## See also

[Joins](#)

LIKE

Retrieves rows where a string expression—typically a column—matches the specified pattern or, if qualified by ANY or ALL, set of patterns. Patterns can contain one or more wildcard characters.

If an ANY or ALL pattern is qualified with NOT, the negation is pushed down to each clause. **NOT LIKE ANY (a, b)** is equivalent to **NOT LIKE a OR NOT LIKE b**. See the examples.

## Syntax

```
string-expression [NOT] { LIKE | ILIKE | LIKEB | ILIKEB }
{ pattern | { ANY | SOME | ALL } (pattern,...) } [ESCAPE 'char']
```

## Arguments

### **string-expression**

String expression, typically a column, to test for instances of the specified [pattern or patterns](#).

### **NOT**

Returns true if the LIKE predicate returns false and vice-versa. When used with ANY or ALL, applies to each value individually.

### **LIKE | ILIKE | LIKEB | ILIKEB**

Type of comparison:

- **LIKE**: Complies with the SQL standard, case-sensitive, operates on UTF-8 character strings, exact behavior depends on collation parameters such as strength. LIKE is [stable](#) for character strings, but [immutable](#) for binary strings
- **ILIKE**: Same as LIKE but case-insensitive.
- **LIKEB**: Performs case-sensitive byte-at-a-time ASCII comparisons, [immutable](#) for character and binary strings.
- **ILIKEB**: Same as LIKEB but case-insensitive.

### **pattern**

A pattern to test against the expression. Pattern strings can contain the following wildcard characters:

- **\_** (underscore): Match any single character.
- **%** (percent): Match any string of zero or more characters.

### **ANY | SOME | ALL**

Apply a comma-delimited list of patterns, where:

- **ANY** and **SOME** return true if any pattern matches, equivalent to logical OR. These options are synonyms.
- **ALL** returns true only if all patterns match, equivalent to logical AND.

### **ESCAPE char**

Escape character, by default backslash ( \ ), used to escape reserved characters: wildcard characters (underscore and percent), and the escape character itself.

This option is enforced only for non-default collations; it is currently unsupported with ANY/ALL pattern matching.

#### Note

Backslash is not valid for binary data type characters. To embed an escape character for binary data types, use **ESCAPE** to specify a valid binary character.

## Substitute symbols

You can substitute the following symbols for LIKE and its variants:

#### Note

ESCAPE usage is not valid for these symbols.

Symbol	Equivalent to:
~~	LIKE
~#	LIKEB
~~*	ILIKE
~#*	ILIKEB
!~~	NOT LIKE
!~#	NOT LIKEB
!~~*	NOT ILIKE
!~#*	NOT ILIKEB

### Pattern matching

LIKE and its variants require that the entire string expression match the specified patterns. To match a sequence of characters anywhere within a string, the pattern must start and end with a percent sign.

LIKE does not ignore trailing white space characters. If the data values to match end with an indeterminate amount of white space, append the wildcard character % to *pattern*.

### Locale dependencies

In the default locale, LIKE and ILIKE handle UTF-8 character-at-a-time, locale-insensitive comparisons. ILIKE handles language-independent case-folding.

In non-default locales, LIKE and ILIKE perform locale-sensitive string comparisons, including some automatic normalization, using the same algorithm as the = operator on VARCHAR types.

ESCAPE expressions evaluate to exactly one octet—or one UTF-8 character for non-default locales.

### Examples

#### Basic pattern matching

The following query searches for names with a common prefix:

```
=> SELECT name FROM people WHERE name LIKE 'Ann%';
 name

 Ann
 Ann Marie
 Anna
(3 rows)
```

### LIKE ANY/ALL

LIKE operators support the keywords ANY and ALL, which let you specify multiple patterns to test against a string expression. For example, the following query finds all names that begin or end with the letter 'A':

```
-> SELECT name FROM people WHERE name LIKE ANY ('A%', '%a');
 name

Alice
Ann
Ann Marie
Anna
Roberta
(5 rows)
```

LIKE ANY usage is equivalent to individual LIKE conditions combined with OR:

```
-> SELECT name FROM people WHERE name LIKE 'A%' OR name LIKE '%a';
 name

Alice
Ann
Ann Marie
Anna
Roberta
(5 rows)
```

Similarly, LIKE ALL is equivalent to individual LIKE conditions combined with AND.

NOT LIKE ANY/ALL

You can use NOT with LIKE ANY or LIKE ALL. NOT does not negate the LIKE expression; instead it negates each clause.

Consider a table with the following contents:

```
-> SELECT name FROM people;
 name

Alice
Ann
Ann Marie
Anna
Richard
Rob
Robert
Roberta
(8 rows)
```

In the following query, **NOT LIKE ANY ('A%', '%a')** is equivalent to **NOT LIKE 'A%' OR NOT LIKE '%a'** , so the only result that is eliminated is **Anna** , which matches both patterns:

```
-> SELECT name FROM people WHERE name NOT LIKE ANY ('A%', '%a');
 name

Alice
Ann
Ann Marie
Richard
Rob
Robert
Roberta
(7 rows)

-- same results:
-> SELECT name FROM people WHERE name NOT LIKE 'A%' OR name NOT LIKE '%a';
```

NOT LIKE ALL eliminates results that satisfy any pattern:

```
=> SELECT name FROM people WHERE name NOT LIKE ALL ('A%', '%a');
 name

Richard
Rob
Robert
(3 rows)
```

-- same results:

```
=> SELECT name FROM people WHERE name NOT LIKE 'A%' AND name NOT LIKE '%a';
```

## Pattern matching in locales

The following example illustrates pattern matching in locales.

```
=> \locale default
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> CREATE TABLE src(c1 VARCHAR(100));
=> INSERT INTO src VALUES (U&'^00DF'); --The sharp s (ß)
=> INSERT INTO src VALUES ('ss');
=> COMMIT;
```

Querying the `src` table in the default locale returns both `ss` and sharp `s`.

```
=> SELECT * FROM src;
 c1
--
ß
ss
(2 rows)
```

The following query combines pattern-matching predicates to return the results from column `c1` :

```
=> SELECT c1, c1 = 'ss' AS equality, c1 LIKE 'ss'
 AS LIKE, c1 ILIKE 'ss' AS ILIKE FROM src;
 c1 | equality | LIKE | ILIKE
-----+-----+-----+-----
ß | f | f | f
ss | t | t | t
(2 rows)
```

The next query specifies unicode format for `c1` :

```
=> SELECT c1, c1 = U&'^00DF' AS equality,
 c1 LIKE U&'^00DF' AS LIKE,
 c1 ILIKE U&'^00DF' AS ILIKE from src;
 c1 | equality | LIKE | ILIKE
-----+-----+-----+-----
ß | t | t | t
ss | f | f | f
(2 rows)
```

Now change the locale to German with a strength of 1 (ignore case and accents):

```

=> \locale LDE_S1
INFO 2567: Canonical locale: 'de'
Standard collation: 'LDE_S1'
German Deutsch
=> SELECT c1, c1 = 'ss' AS equality,
c1 LIKE 'ss' AS LIKE, c1 ILIKE 'ss' AS ILIKE from src;
c1 | equality | LIKE | ILIKE
-----+-----
0 | t | t | t
ss | t | t | t
(2 rows)

```

This example illustrates binary data types with pattern-matching predicates:

```

=> CREATE TABLE t (c BINARY(1));
CREATE TABLE
=> INSERT INTO t VALUES (HEX_TO_BINARY('0x00')), (HEX_TO_BINARY('0xFF'));
OUTPUT

 2
(1 row)

=> COMMIT;
COMMIT
=> SELECT TO_HEX(c) FROM t;
TO_HEX

00
ff
(2 rows)

=> SELECT * FROM t;
c

\000
\377
(2 rows)

=> SELECT c, c = '000', c LIKE '000', c ILIKE '000' from t;
c | ?column? | ?column? | ?column?
-----+-----
\000 | t | t | t
\377 | f | f | f
(2 rows)

=> SELECT c, c = '377', c LIKE '377', c ILIKE '377' FROM t;
c | ?column? | ?column? | ?column?
-----+-----
\000 | f | f | f
\377 | t | t | t
(2 rows)

```

## NULL

Tests for null values. The expression can be a column name, literal, or function.

### Syntax

```
value-expression IS [NOT] NULL
```

### Examples

Column name:

```
=> SELECT date_key FROM date_dimension WHERE date_key IS NOT NULL;
```

```
date_key

1
366
1462
1097
2
3
6
7
8
```

#### Function:

```
=> SELECT MAX(household_id) IS NULL FROM customer_dimension;
```

```
?column?

1
(1 row)
```

#### Literal:

```
=> SELECT 'a' IS NOT NULL;
```

```
?column?

1
(1 row)
```

## Hints

Hints are directives that you embed within a query or [directed query](#). They conform to the following syntax:

```
/*+hint-name[, hint-name]...*/
```

Hints are bracketed by comment characters `/*+` and `*/`, which can enclose multiple comma-delimited hints. For example:

```
SELECT /*+syntactic_join,verbatim*/
```

### Restrictions

When embedding hints in a query, be aware of the following restrictions:

- Do not embed spaces in the comment characters `/*` and `*/`.
- In general, spaces are allowed before and after the plus (+) character and *hint-name*; however, some third-party tools do not support spaces embedded inside `/*` +.

### Supported hints

Vertica supports the following hints:

#### General hints

Hint	Description
<a href="#">ALLNODES</a>	Qualifies an <a href="#">EXPLAIN</a> statement to request a query plan that assumes all nodes are active.
<a href="#">EARLY_MATERIALIZATION</a>	Specifies early materialization of a table for the current query.
<a href="#">ENABLE_WITH_CLAUSE_MATERIALIZATION</a>	Enables and disables <a href="#">WITH clause</a> materialization for a specific query.
<a href="#">LABEL</a>	Labels a query so you can identify it for profiling and debugging.
<a href="#">SKIP_STATISTICS</a>	Directs the optimizer to produce a query plan that incorporates only minimal statistics.

## Eon Mode hints

Hint	Description
<a href="#">DEPOT_FETCH</a>	Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query.
<a href="#">ECSMODE</a>	Specifies the <a href="#">elastic crunch scaling (ECS) strategy</a> for dividing shard data among its subscribers.

## Join hints

Hint	Description
<a href="#">SYNTACTIC_JOIN</a>	Enforces join order and enables other join hints.
<a href="#">DISTRIB</a>	Sets the input operations for a distributed join to broadcast, resegment, local, or filter.
<a href="#">GBYTYPE</a>	Specifies which algorithm—GROUPBY HASH or GROUPBY PIPELINED—the Vertica query optimizer should use to implement a <a href="#">GROUP BY</a> clause.
<a href="#">JTYPE</a>	Enforces the join type: merge or hash join.
<a href="#">UTYPE</a>	Specifies how to combine UNION ALL input.

## Projection hints

Hint	Description
<a href="#">PROJS</a>	Specifies one or more projections to use for a queried table.
<a href="#">SKIP_PROJS</a>	Specifies which projections to avoid using for a queried table.

## Directed query hints

The following hints are only supported by directed queries:

Hint	Description
<a href="#">:c</a>	Marks a query constant that must be included in an input query; otherwise, that input query is disqualified from using the directed query.
<a href="#">:v</a>	Maps an input query constant to one or more annotated query constants.
<a href="#">VERBATIM</a>	Enforces execution of an annotated query exactly as written.

## In this section

- [VERBATIM](#)

:c

In a directed query, marks a query constant that must be included in an input query; otherwise, that input query is disqualified from using the directed query.

Syntax

```
/*+:c*/
```

Usage

By default, optimizer-generated directed queries set ignore constant ( :v ) hints on predicate constants. You can override this behavior by setting the :c hint on input query constants that must not be ignored. For example, the following statement creates a directed query that can be used only for input queries where the join predicate constant is the same as in the original input query— 8 :

```
=> CREATE DIRECTED QUERY OPTIMIZER simpleJoin_KeepPredicateConstant SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8 /*+:c*/;
CREATE DIRECTED QUERY
=> ACTIVATE DIRECTED QUERY simpleJoin_KeepPredicateConstant;
```

See also

[Conserving Predicate Constants in Directed Queries](#)

:v

In a directed query, marks an input query constant that the optimizer ignores when it considers whether to use the directed query for a given query. Use this hint to create a directed query that can be used for multiple variants of an input query.

Vertica also supports **IGNORECONST** as an alias of :v . Optimizer-generated directed queries automatically mark predicate constants in input and annotated queries with :v hints.

For details, see [Ignoring constants in directed queries](#).

Syntax

```
/*+:v(arg)*/
/*+IGNORECONST(arg)*/
```

**arg**

Integer argument that is used in the directed query to pair each input query :v hint with one or more annotated query :v hints.

Examples

See [Ignoring constants in directed queries](#).

ALLNODES

Qualifies an **EXPLAIN** statement to request a query plan that assumes all nodes are active. If you omit this hint, the **EXPLAIN** statement produces a query plan that takes into account any nodes that are currently down.

Syntax

```
EXPLAIN /*+ALLNODES*/
```

Examples

In the following example, the **ALLNODES** hint requests a query plan that assumes all nodes are active.

## QUERY PLAN DESCRIPTION:

-----

Opt Vertica Options

-----

PLAN\_ALL\_NODES\_ACTIVE

```
EXPLAIN /*+ALLNODES*/ select * from Emp_Dimension;
```

Access Path:

+--STORAGE ACCESS for Emp\_Dimension [Cost: 125, Rows: 10K (NO STATISTICS)] (PATH ID: 1)

| Projection: public.Emp\_Dimension\_b0

| Materialize: Emp\_Dimension.Employee\_key, Emp\_Dimension.Employee\_gender, Emp\_Dimension.Courtesy\_title, Emp\_Dimension.Employee\_first\_name, Emp\_Dimension.Employee\_middle\_initial, Emp\_Dimension.Employee\_last\_name, Emp\_Dimension.Employee\_age, Emp\_Dimension.Employee\_birthdate, Emp\_Dimension.Employee\_street, Emp\_Dimension.Employee\_city, Emp\_Dimension.Employee\_state, Emp\_Dimension.Employee\_region, Emp\_Dimension.Employee\_position

| Execute on: All Nodes

## DEPOT\_FETCH

Eon Mode only

Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query. This hint overrides configuration parameter [DepotOperationsForQuery](#).

Syntax

```
SELECT /*+DEPOT_FETCH (option)*/
```

Arguments

**\* option \***

Specifies behavior when the depot does not contain queried file data, one of the following:

- **ALL** (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
- **FETCHES** : Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
- **NONE** : Do not fetch file data to the depot, read the queried data directly from communal storage.

Examples

```
SELECT /*+DEPOT_FETCH(All)*/ count(*) FROM bar;
SELECT /*+DEPOT_FETCH(FETCHES)*/ count(*) FROM bar;
SELECT /*+DEPOT_FETCH(NONE)*/ count(*) FROM bar;
```

## DISTRIB

The DISTRIB hint specifies to the optimizer how to distribute join key data in order to implement a join. If a specified distribution is not feasible, the optimizer ignores the hint and throws a warning.

The following requirements apply:

- Queries that include the DISTRIB hint must also include the SYNTACTIC\_JOIN hint. Otherwise, the optimizer ignores the DISTRIB hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

Syntax

```
JOIN /*+DISTRIB(outer-join, inner-join)*/
```

Arguments

**outer-join**

**inner-join**

Specifies how to distribute data on the outer and inner joins:

- **L** (local): Inner and outer join keys are identically segmented on each node, join locally.
- **R** (resegment): Inner and outer join keys are not identically segmented. Resegment join-key data before implementing the join.

- **B** (broadcast): Inner and outer join keys are not identically segmented. Broadcast data of this join key to other nodes before implementing the join.
- **F** (filter): Join table is unsegmented. Filter data as needed by the other join key before implementing the join.
- **A** (any): Let the optimizer choose the distribution method that it considers to be most cost-effective.

## Examples

In the following query, the join is qualified with a **DISTRIB** hint of `/*+DISTRIB(L,R)*/`. This hint tells the optimizer to resegment data of join key `stores.store_key` before joining it to the `sales.store_key` data:

```
SELECT /*+SYNTACTIC_JOIN*/ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date
FROM (store.storeSales AS sales JOIN /*+DISTRIB(L,R),JTYPE(H)*/ store.store_dimension AS stores ON (sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01'::date) ORDER BY sales.store_key, sales.sale_date;
```

## EARLY\_MATERIALIZATION

Specifies early materialization of a table for the current query. A query can include this hint for any number of tables. Typically, the query optimizer delays materialization until late in the query execution process. This hint overrides any choices that the optimizer otherwise would make.

This hint can be useful in cases where late materialization of join inputs precludes other optimizations—for example, pushing aggregation down the joins, or using live aggregate projections. In these cases, qualifying a join input with **EARLY\_MATERIALIZATION** can enable the optimizations.

## Syntax

```
table-name [[AS] alias] /*+EARLY_MATERIALIZATION*/
```

## ECSMODE

Eon Mode only

Sets the [ECS strategy](#) that the optimizer uses when it divides responsibility for processing shard data among subscriber nodes. This hint is applied only if the subcluster uses [elastic crunch scaling](#) (ECS).

## Syntax

```
SELECT /*+ECSMODE(option)*/
```

## Arguments

**\* option \***

Specifies the strategy to use when dividing shard data among its subscribing nodes, one of the following:

- **AUTO** : The optimizer chooses the strategy to use, useful only if ECS mode is set at the session level (see [Setting the ECS Strategy for the Session or Database](#)).
- **IO\_OPTIMIZED** : Use I/O-optimized strategy.
- **COMPUTE\_OPTIMIZED** : Use compute-optimized strategy.
- **NONE** : Disable use of ECS for this query. Only participating nodes are involved in query execution; collaborating nodes are not.

## Example

The following example shows the query plan for a simple single-table query that is forced to use the compute-optimized strategy:

```
=> EXPLAIN SELECT /*+ECSMODE(COMPUTE_OPTIMIZED)*/ employee_last_name,
employee_first_name,employee_age
FROM employee_dimension
ORDER BY employee_age DESC;
```

### QUERY PLAN

#### QUERY PLAN DESCRIPTION:

The execution of this query involves non-participating nodes.  
Crunch scaling strategy preserves data segmentation

## ENABLE\_WITH\_CLAUSE\_MATERIALIZATION

Enables materialization of all queries in the current WITH clause. Otherwise, materialization is set by configuration parameter `WithClauseMaterialization`, by default set to 0 (disabled). If `WithClauseMaterialization` is disabled, materialization is automatically cleared when the primary query of the WITH clause returns. For details, see [Materialization of WITH clause](#).

Syntax

```
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/
```

GBYTYPE

Specifies which algorithm—GROUPBY HASH or GROUPBY PIPELINED—the Vertica query optimizer should use to implement a [GROUP BY](#) clause. If both algorithms are valid for this query, the query optimizer chooses the specified algorithm over the algorithm that the query optimizer might otherwise choose in its query plan.

#### Note

Vertica uses the GROUPBY PIPELINED algorithm only if the query and one of its projections comply with GROUPBY PIPELINED [requirements](#). Otherwise, Vertica issues a warning and uses GROUPBY HASH.

For more information about both algorithms, see [GROUP BY implementation options](#).

Syntax

```
GROUP BY /*+GBYTYPE(HASH | PIPE)*/
```

Arguments

#### HASH

Use the GROUPBY HASH algorithm.

#### PIPE

Use the GROUPBY PIPELINED algorithm.

Examples

See [Controlling GROUPBY Algorithm Choice](#).

JFMT

Specifies how to size VARCHAR column data when joining tables on those columns, and buffer that data accordingly. The JFMT hint overrides the default behavior that is set by configuration parameter [JoinDefaultTupleFormat](#), which can be set at database and session levels.

For more information, see [Joining variable length string data](#).

Syntax

```
JOIN /*+JFMT(format-type)*/
```

Arguments

#### *format-type*

Specifies how to format VARCHAR column data when joining tables on those columns, and buffers the data accordingly. Set to one of the following:

- **f** (fixed): Use join column metadata to size column data to a fixed length, and buffer accordingly.
- **v** (variable): Use the actual length of join column data, so buffer size varies for each join.

For example:

```
SELECT /*+SYNTACTIC_JOIN*/ s.store_region, SUM(e.vacation_days) TotalVacationDays
FROM public.employee_dimension e
JOIN /*+JFMT(f)*/ store.store_dimension s ON s.store_region=e.employee_region
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

Requirements

- Queries that include the **JFMT** hint must also include the **SYNTACTIC\_JOIN** hint. Otherwise, the optimizer ignores the **JFMT** hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

JTYPE

Specifies the join algorithm as hash or merge.

Use the JTYPE hint to specify the algorithm the optimizer uses to join table data. If the specified algorithm is not feasible, the optimizer ignores the hint and throws a warning.

Syntax

```
JOIN /*+JTYPE(join-type)*/
```

Arguments

#### **join-type**

One of the following:

- **H** : Hash join
- **M** : Merge join, valid only if both join inputs are already sorted on the join columns, otherwise Vertica ignores it and throws a warning. The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.
- **FM** : Forced merge join. Before performing the merge, the optimizer re-sorts the join inputs. Join columns must be of the same type and precision or scale, except that string columns can have different lengths.

A value of **FM** is valid only for simple join conditions. For example:

```
=> SELECT /*+SYNTACTIC_JOIN*/ * FROM x JOIN /*+JTYPE(FM)*/ y ON x.c1 = y.c1;
```

Requirements

- Queries that include the JTYPE hint must also include the SYNTACTIC\_JOIN hint. Otherwise, the optimizer ignores the JTYPE hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

LABEL

Assigns a label to a statement so it can [easily be identified](#) to evaluate performance and debug problems.

LABEL hints are valid in the following statements:

- [COPY](#)
- [DELETE](#)
- EXPORT statements:
  - [EXPORT TO DELIMITED](#)
  - [EXPORT TO ORC](#)
  - [EXPORT TO PARQUET](#)
  - [EXPORT TO VERTICA](#)
- [INSERT](#)
- [MERGE](#)
- [SELECT](#)
- [UPDATE](#)
- [UNION](#) : Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

Syntax

```
statement-name /*+LABEL (label-string)*/
```

Arguments

#### **label-string**

A string that is up to 128 octets long. If enclosed with single quotes, *label-string* can contain embedded spaces.

Examples

See [Labeling statements](#).

PROJS

Specifies one or more projections to use for a queried table.

The PROJS hint can specify multiple projections; the optimizer determines which ones are valid and uses the one that is most cost-effective for the queried table. If no hinted projection is valid, the query returns a warning and ignores projection hints.

Syntax

```
FROM ``table-name`` /*+PROJS([[``database``.]``schema``]``projection``[,...])*/
```

## Arguments

[ **database** .] **schema**

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

## projection

The projection to use. You can specify a list of comma-delimited projections.

## Examples

The **employee\_dimension** table has two projections: segmented superprojection **public.employee\_dimension**, which includes all table columns; and the unsegmented projection **public.employee\_dimension\_rep**, which includes a subset of the columns:

```
=> SELECT export_objects(", 'employee_dimension');
 export_objects
```

---

```
CREATE TABLE public.employee_dimension
(
 employee_key int NOT NULL,
 employee_gender varchar(8),
 courtesy_title varchar(8),
 employee_first_name varchar(64),
 employee_middle_initial varchar(8),
 employee_last_name varchar(64),
 employee_age int,
 hire_date date,
 employee_street_address varchar(256),
 employee_city varchar(64),
 employee_state char(2),
 employee_region char(32),
 job_title varchar(64),
 reports_to int,
 salaried_flag int,
 annual_salary int,
 hourly_rate float,
 vacation_days int,
 CONSTRAINT C_PRIMARY PRIMARY KEY (employee_key) DISABLED
);
```

```
CREATE PROJECTION public.employee_dimension
```

```
...
```

```
AS
```

```
SELECT employee_dimension.employee_key,
 employee_dimension.employee_gender,
 employee_dimension.courtesy_title,
 employee_dimension.employee_first_name,
 employee_dimension.employee_middle_initial,
 employee_dimension.employee_last_name,
 employee_dimension.employee_age,
 employee_dimension.hire_date,
 employee_dimension.employee_street_address,
 employee_dimension.employee_city,
 employee_dimension.employee_state,
 employee_dimension.employee_region,
 employee_dimension.job_title,
 employee_dimension.reports_to,
 employee_dimension.salaried_flag,
 employee_dimension.annual_salary,
 employee_dimension.hourly_rate,
 employee_dimension.vacation_days
FROM public.employee_dimension
```

```

ORDER BY employee_dimension.employee_key
SEGMENTED BY hash(employee_dimension.employee_key) ALL NODES KSAFE 1;

CREATE PROJECTION public.employee_dimension_rep
...
AS
SELECT employee_dimension.employee_key,
 employee_dimension.employee_gender,
 employee_dimension.employee_first_name,
 employee_dimension.employee_middle_initial,
 employee_dimension.employee_last_name,
 employee_dimension.employee_age,
 employee_dimension.employee_street_address,
 employee_dimension.employee_city,
 employee_dimension.employee_state,
 employee_dimension.employee_region
FROM public.employee_dimension
ORDER BY employee_dimension.employee_key
UNSEGMENTED ALL NODES;

SELECT MARK_DESIGN_KSAFE(1);

(1 row)

```

The following query selects all table columns from `employee_dimension` and includes the `PROJS` hint, which specifies both projections. `public.employee_dimension_rep` does not include all columns in the queried table, so the optimizer cannot use it. The segmented projection includes all table columns so the optimizer uses it, as verified by the following query plan:

```

=> EXPLAIN SELECT * FROM employee_dimension /*+PROJS('public.employee_dimension_rep', 'public.employee_dimension')*/;

QUERY PLAN DESCRIPTION:

EXPLAIN SELECT * FROM employee_dimension /*+PROJS('public.employee_dimension_rep', 'public.employee_dimension')*/;

Access Path:
+-STORAGE ACCESS for employee_dimension [Cost: 177, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
 | Projection: public.employee_dimension_b0

```

## SKIP\_PROJS

Specifies which projections to avoid using for a queried table. If `SKIP_PROJS` excludes all available projections that are valid for the query, the optimizer issues a warning and ignores the projection hints.

### Syntax

```
FROM table-name /*+SKIP_PROJS([[database.]schema.]projection[,...])*/
```

### Arguments

**[ *database.* ] *schema***

Database and `schema`. The default schema is `public`. If you specify a database, it must be the current database.

### *projection*

A projection to skip. You can specify a list of comma-delimited projections.

### Examples

In this example, the EXPLAIN output shows that the optimizer uses the projection `public.employee_dimension_b0` for a given query:

QUERY PLAN DESCRIPTION:

-----

```
EXPLAIN SELECT employee_last_name, employee_first_name, employee_city, job_title FROM employee_dimension;
```

Access Path:

+--STORAGE ACCESS for employee\_dimension [Cost: 59, Rows: 10K (NO STATISTICS)] (PATH ID: 1)

| **Projection: public.employee\_dimension\_b0**

| Materialize: employee\_dimension.employee\_first\_name, employee\_dimension.employee\_last\_name, employee\_dimension.employee\_city, employee\_dimension.job\_title

| Execute on: All Nodes

You can use the [SKIP\\_PROJS](#) hint to avoid using this projection. If another projection is available that is valid for this query, the optimizer uses it instead:

QUERY PLAN DESCRIPTION:

-----

```
EXPLAIN SELECT employee_last_name, employee_first_name, employee_city, job_title FROM employee_dimension
/*+SKIP_PROJS('public.employee_dimension')*/;
```

Access Path:

+--STORAGE ACCESS for employee\_dimension [Cost: 156, Rows: 10K (NO STATISTICS)] (PATH ID: 1)

| **Projection: public.employee\_dimension\_super**

| Materialize: employee\_dimension.employee\_first\_name, employee\_dimension.employee\_last\_name, employee\_dimension.employee\_city, employee\_dimension.job\_title

| Execute on: Query Initiator

## SKIP\_STATISTICS

Directs the optimizer to produce a query plan that incorporates only the minimal statistics that are collected by [ANALYZE\\_ROW\\_COUNT](#). The optimizer ignores other statistics that would otherwise be used, that are generated by [ANALYZE\\_STATISTICS](#) and [ANALYZE\\_STATISTICS\\_PARTITION](#). This hint is especially useful when used in queries on small tables, where the amount of time required to collect full statistics is often greater than actual execution time.

### Syntax

```
SELECT /*+SKIP_STAT[ISTICS]S*/
```

### EXPLAIN output

**EXPLAIN** returns the following output for a query that includes [SKIP\\_STATISTICS](#) (using its shortened form [SKIP\\_STATS](#)):

```
=> EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||', '||customer_state, customer_age
FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;
```

QUERY PLAN DESCRIPTION:

-----

```
EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||', '||customer_state,
customer_age FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;
```

Access Path:

```
+--STORAGE ACCESS for customer_dimension [Cost: 2K, Rows: 10K (STATISTICS SKIPPED)] (PATH ID: 1)
```

```
| Projection: public.customer_dimension_b0
```

```
| Materialize: public.customer_dimension.customer_age, public.customer_dimension.customer_key, public.customer_dimensi
on.customer_name, public.customer_dimension.customer_gender, public.customer_dimension.customer_city, public.customer_di
mension.customer_state
```

```
| Filter: (public.customer_dimension.customer_region = 'East')
```

```
| Filter: (public.customer_dimension.customer_age > 60)
```

```
| Execute on: All Nodes
```

...

## SYNTACTIC\_JOIN

Enforces join order and enables other join hints.

In order to achieve optimal performance, the optimizer often overrides a query's specified join order. By including the **SYNTACTIC\_JOIN** hint, you can ensure that the optimizer enforces the query's join order exactly as specified. One requirement applies: the join syntax must conform with ANSI SQL-92 conventions.

The **SYNTACTIC\_JOIN** hint must immediately follow **SELECT** . If the annotated query includes another hint that must also follow **SELECT** , such as **VERBATIM** , combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim*/
```

Syntax

```
SELECT /*+SYN[TACTIC]_JOIN*/
```

Examples

In the following examples, the optimizer produces different plans for two queries that differ only by including or excluding the **SYNTACTIC\_JOIN** hint.

Excludes SYNTACTIC\_JOIN:

```
EXPLAIN SELECT sales.store_key, stores.store_name, products.product_description, sales.sales_quantity, sales.sale_date
FROM (store.store_sales sales JOIN products ON sales.product_key=products.product_key)
JOIN store.store_dimension stores ON sales.store_key=stores.store_key
WHERE sales.sale_date='2014-12-01' order by sales.store_key, sales.sale_date;
```

Access Path:

```
+--SORT [Cost: 14K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 11K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND ROBIN) Inner (RESEGMENT)
|| Join Cond: (sales.product_key = products.product_key)
|| Materialize at Input: sales.store_key, sales.product_key, sales.sale_date, sales.sales_quantity
|| Execute on: All Nodes
|| +-- Outer -> JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
||| Join Cond: (sales.store_key = stores.store_key)
||| Execute on: All Nodes
||| +-- Outer -> STORAGE ACCESS for sales [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
|||| Projection: store.store_sales_b0
|||| Materialize: sales.store_key
|||| Filter: (sales.sale_date = '2014-12-01'::date)
|||| Execute on: All Nodes
|||| Runtime Filter: (SIP1(HashJoin): sales.store_key)
||| +-- Inner -> STORAGE ACCESS for stores [Cost: 34, Rows: 250] (PATH ID: 5)
|||| Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
|||| Materialize: stores.store_key, stores.store_name
|||| Execute on: All Nodes
|| +-- Inner -> STORAGE ACCESS for products [Cost: 3K, Rows: 60K (NO STATISTICS)] (PATH ID: 6)
||| Projection: public.products_b0
||| Materialize: products.product_key, products.product_description
||| Execute on: All Nodes
```

Includes SYNTACTIC\_JOIN:

```
EXPLAIN SELECT /*+SYNTACTIC_JOIN*/ sales.store_key, stores.store_name, products.product_description, sales.sales_quantity, sales.sale_date
FROM (store.store_sales sales JOIN products ON sales.product_key=products.product_key)
JOIN store.store_dimension stores ON sales.store_key=stores.store_key
WHERE sales.sale_date='2014-12-01' order by sales.store_key, sales.sale_date;
```

#### Access Path:

```
+--SORT [Cost: 11K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 8K, Rows: 100K (NO STATISTICS)] (PATH ID: 2)
|| Join Cond: (sales.store_key = stores.store_key)
|| Execute on: All Nodes
|| +-- Outer -> JOIN HASH [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 3) Outer (BROADCAST)(LOCAL ROUND ROBIN)
||| Join Cond: (sales.product_key = products.product_key)
||| Execute on: All Nodes
||| Runtime Filter: (SIP1(HashJoin): sales.store_key)
||| +-- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
||| | Projection: store.store_sales_b0
||| | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
||| | Filter: (sales.sale_date = '2014-12-01'::date)
||| | Execute on: All Nodes
||| +-- Inner -> STORAGE ACCESS for products [Cost: 3K, Rows: 60K (NO STATISTICS)] (PATH ID: 5)
||| | Projection: public.products_b0
||| | Materialize: products.product_key, products.product_description
||| | Execute on: All Nodes
|| +-- Inner -> STORAGE ACCESS for stores [Cost: 34, Rows: 250] (PATH ID: 6)
|| | Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
|| | Materialize: stores.store_key, stores.store_name
|| | Execute on: All Nodes
```

## UTYPE

Specifies how to combine [UNION ALL](#) input.

### Syntax

```
UNION ALL /*+UTYPE(union-type)*/
```

### Arguments

#### **union-type**

One of the following values:

- **U**: Concatenates [UNION ALL](#) input (default).
- **M**: Merges [UNION ALL](#) input in the same sort order as the source query results. This option requires all input from the source queries to use the same sort order; otherwise, Vertica throws a warning and concatenates the [UNION ALL](#) input.

#### Note

The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.

### Requirements

Queries that include the [UTYPE](#) hint must also include the [SYNTACTIC\\_JOIN](#) hint. Otherwise, the optimizer ignores the [UTYPE](#) hint and throws a warning.

## VERBATIM

Enforces execution of an annotated query exactly as written.

VERBATIM directs the optimizer to create a query plan that incorporates all hints in a annotated query. Furthermore, it directs the optimizer not to apply its own plan development processing on query plan components that pertain to those hints.

Usage of this hint varies between [optimizer-generated](#) and [custom](#) directed queries, as described below.

## Syntax

```
SELECT /*+ VERBATIM*/
```

## Requirements

The VERBATIM hint must immediately follow SELECT. If the annotated query includes another hint that must also follow SELECT, such as SYNTACTIC\_JOIN, combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim*/
```

## Optimizer-generated directed queries

The optimizer always includes the VERBATIM hint in the annotated queries that it [generates for directed queries](#). For example, given the following CREATE DIRECTED QUERY OPTIMIZER statement:

```
=> CREATE DIRECTED QUERY OPTIMIZER getStoreSales SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-01' /*+IGNORECONST(1)*/ AND stores.store_name='Store1' /*+IGNORECONST(2)*/ ORDER BY sales.store_key, sales.sale_date;
CREATE DIRECTED QUERY
```

The optimizer generates an annotated query that includes the VERBATIM hint:

```
=> SELECT query_name, annotated_query FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name = 'getStoreSales';
-[RECORD 1]---+-----
query_name | getStoreSales
annotated_query | SELECT /*+ syntactic_join,verbatim*/ sales.store_key AS store_key, stores.store_name AS store_name, sales.product_description AS product_description, sales.sales_quantity AS sales_quantity, sales.sale_date AS sale_date
FROM (store.storeSales AS sales/*+projs('store.storeSales')*/ JOIN /*+Distrib(L,L),JType(H)*/ store.store_dimension AS stores/*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON (sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01'::date /*+IgnoreConst(1)*/) AND (stores.store_name = 'Store1'::varchar(6) /*+IgnoreConst(2)*/)
ORDER BY 1 ASC, 5 ASC
```

When the optimizer uses this directed query, it produces a query plan that is equivalent to the query plan that it used when it created the directed query:

```
=> ACTIVATE DIRECTED QUERY getStoreSales;
```

```
ACTIVATE DIRECTED QUERY
```

```
=> EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;
```

QUERY PLAN DESCRIPTION:

-----

```
EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;
```

The following active directed query(query name: getStoreSales) is being executed:

```
SELECT /*+syntactic_join,verbatim*/ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM (store.storeSales sales/*+projs('store.storeSales')*/ JOIN /*+Distrib('L', 'L'), JType('H')*/store.store_dimension stores /*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON ((sales.store_key = stores.store_key))) WHERE ((sales.sale_date = '2014-12-04'::date) AND (stores.store_name = 'Store14'::varchar(7))) ORDER BY sales.store_key, sales.sale_date
```

Access Path:

```
+JOIN HASH [Cost: 463, Rows: 622 (NO STATISTICS)] (PATH ID: 2)
| Join Cond: (sales.store_key = stores.store_key)
| Materialize at Output: sales.sale_date, sales.sales_quantity, sales.product_description
| Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for sales [Cost: 150, Rows: 155K (NO STATISTICS)] (PATH ID: 3)
|| Projection: store.storeSales_b0
|| Materialize: sales.store_key
|| Filter: (sales.sale_date = '2014-12-04'::date)
|| Execute on: All Nodes
|| Runtime Filter: (SIP1(HashJoin): sales.store_key)
| +- Inner -> STORAGE ACCESS for stores [Cost: 35, Rows: 2] (PATH ID: 4)
|| Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
|| Materialize: stores.store_name, stores.store_key
|| Filter: (stores.store_name = 'Store14')
|| Execute on: All Nodes
```

Custom directed queries

The VERBATIM hint is included in a [custom directed query](#) only if you explicitly include it in the annotated query that you write for that directed query. When the optimizer uses that directed query, it respects the VERBATIM hint and creates a query plan accordingly.

If you omit the VERBATIM hint when you create a custom directed query, the hint is not stored with the annotated query. When the optimizer uses that directed query, it applies its own plan development processing on the annotated query before it generates a query plan. This query plan might not be equivalent to the query plan that the optimizer would have generated for the Vertica version in which the directed query was created.

Window clauses

When used with an [analytic function](#), window clauses specify how to partition and sort function input, as well as how to frame input with respect to the current row. When used with a single-phase transform function, the PARTITION ROW and PARTITION LEFT JOIN window clauses support single-row partitions for single-phase transform functions, rather than analytic functions.

In this section

- [Window partition clause](#)
- [Window order clause](#)
- [Window frame clause](#)
- [Window name clause](#)

Window partition clause

When specified, a window partition clause divides the rows of the function input based on user-provided expressions. If no expression is provided, the partition clause can improve query performance by using parallelism. If you do not specify a window partition clause, all input rows are treated as a single partition.

Window partitioning is similar to the GROUP BY clause. However, PARTITION BEST and PARTITION NODES may only be used with analytic functions and return only one result per input row, while PARTITION ROW and PARTITION LEFT JOIN can be used for single-phase transform functions and return multiple values per input row.

When used with analytic functions, results are computed per partition and start over again (reset) at the beginning of each subsequent partition.

#### Syntax

```
{ PARTITION BY expression[,...]
 | PARTITION BEST
 | PARTITION NODES
 | PARTITION ROW
 | PARTITION LEFT JOIN }
```

#### Arguments

##### **PARTITION BY** *expression*

Expression on which to sort the partition, where *expression* can be a column, constant, or an arbitrary expression formed on columns. Use **PARTITION BY** for functions with specific partitioning requirements.

##### **PARTITION BEST**

Use parallelism to improve performance for multi-threaded queries across multiple nodes.

**OVER(PARTITION BEST)** provides the best performance on multi-threaded queries across multiple nodes.

The following considerations apply to using **PARTITION BEST** :

- Use **PARTITION BEST** for analytic functions that have no partitioning requirements and are thread safe—for example, a one-to-many transform.
- Do not use **PARTITION BEST** on user-defined transform functions (UDTFs) that are not thread-safe. Doing so can produce an error or incorrect results. If a UDTF is not thread safe, use **PARTITION NODES** .

##### **PARTITION NODES**

Use parallelism to improve performance for single-threaded queries across multiple nodes.

**OVER(PARTITION NODES)** provides the best performance on single-threaded queries across multiple nodes.

##### **PARTITION ROW , PARTITION LEFT JOIN**

Use to feed input partitions of exactly one row. If used, any arbitrary expression may be used in the query target list alongside the UDTF. PARTITION LEFT JOIN returns a row of NULLs if an input row would otherwise produce no output.

May not be used for analytic functions or multi-phase transform functions. Note that only one PARTITION ROW transform function is allowed in the target list for each level of the query.

#### Examples

See [Window partitioning](#).

#### Window order clause

Specifies how to sort rows that are supplied to an analytic function. If the OVER clause also includes a [window partition clause](#), rows are sorted within each partition.

The window order clause only specifies order within a window result set. The query can have its own [ORDER BY](#) clause outside the OVER clause. This has precedence over the window order clause and orders the final result set.

A window order clause also creates a default [window frame](#) if none is explicitly specified.

#### Syntax

```
ORDER BY { expression [ASC | DESC [NULLS { FIRST | LAST | AUTO }]]
 }[,...]
```

#### Arguments

##### *expression*

A column, constant, or arbitrary expression formed on columns on which to sort input rows.

##### **ASC | DESC**

Sort order: ascending (default) or descending.

##### **NULLS {FIRST | LAST | AUTO}**

How to position nulls. **NULLS AUTO** means to choose the positioning that is most efficient for this query.

**ASC** defaults to **NULLS LAST** and **DESC** defaults to **NULLS FIRST** .

If you omit all sort qualifiers, Vertica uses **ASC NULLS LAST** .

For more information, see [NULL sort order](#) and [Runtime sorting of NULL values in analytic functions](#) .

## Examples

See [Window ordering](#) .

## Window frame clause

Specifies a window frame, which comprises a set of rows relative to the row that is currently being evaluated by an analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly. If the **OVER** clause also specifies a [partition](#) , Vertica also checks that window boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

## Syntax

```
{ ROWS | RANGE } { BETWEEN start-point AND end-point } | start-point
```

*start-point* | *end-point*:

```
{ UNBOUNDED {PRECEDING | FOLLOWING}
 | CURRENT ROW
 | constant-value {PRECEDING | FOLLOWING}}
```

## Arguments

### **ROWS | RANGE**

Whether to interpret window frame dimensions as physical ( **ROWS** ) or logical ( **RANGE** ) offsets from the current row. See [ROWS versus RANGE](#) below for details.

### **BETWEEN *start-point* AND *end-point***

First and last rows of the window, where *start-point* and *end-point* can be one of the following:

- **UNBOUNDED {PRECEDING | FOLLOWING}** : The current partition's first ( **PRECEDING** ) or last ( **FOLLOWING** ) row.
- **CURRENT ROW** : The current row or value.
- ***constant-value* {PRECEDING | FOLLOWING}** : A constant value or expression that evaluates to a constant value. This value is interpreted as either a physical or logical offset from the current row, depending on whether you use **ROWS** or **RANGE**. See [ROWS versus RANGE](#) for other restrictions.

*start-point* must resolve to a row or value that is less than or equal to *end-point* .

### ***start-point***

If **ROWS** or **RANGE** specifies only a start point, Vertica uses the current row as the end point and creates the window frame accordingly. In this case, *start-point* must resolve to a row that is less than or equal to the current row.

## Requirements

In order to specify a window frame, the **OVER** must also specify a [window order \(ORDER BY\) clause](#) . If the **OVER** clause omits specifying a window frame, the function creates a default window that extends from the current row to the first row in the current partition. This is equivalent to the following clause:

```
RANGE UNBOUNDED PRECEDING AND CURRENT ROW
```

## ROWS versus RANGE

The window frame's offset from the current row can be physical or logical:

- **ROWS** (physical): the start and end points are relative to the current row. If either is a constant value, it must evaluate to a positive integer.
- **RANGE** (logical): the start and end points represent a logical offset, such as time. The range value must match the [window order \(ORDER BY\) clause](#) data type: NUMERIC, DATE/TIME, FLOAT or INTEGER.

When setting constant values for **ROWS** , the constant must evaluate to a positive INTEGER.

When setting constant values for **RANGE** , the following requirements apply:

- The constant must evaluate to a positive numeric value or INTERVAL literal.

- If the constant evaluates to a NUMERIC value, the ORDER BY column type must be a NUMERIC data type.
- If the constant evaluates to an INTERVAL DAY TO SECOND subtype, the ORDER BY column type must be one of the following: TIMESTAMP, TIME, DATE, or INTERVAL DAY TO SECOND.
- If the constant evaluates to an INTERVAL YEAR TO MONTH, the ORDER BY column type must be one of the following: TIMESTAMP, DATE, or INTERVAL YEAR TO MONTH.
- The [window order clause](#) can specify only one expression.

Examples

See [Window framing](#).

Window name clause

Defines a named window that specifies window partition and order clauses for an analytic function. This window is specified in the function's **OVER** clause. Named windows can be useful when you write queries that invoke multiple analytic functions with similar **OVER** clauses, such as functions that use the same partition ( **PARTITION BY** ) clauses.

Syntax

```
WINDOW window-name AS (window-partition-clause [window-order-clause])
```

Arguments

**WINDOW** *window-name*

A window name that is unique within the same query.

[window-partition-clause](#) [ [window-order-clause](#) ]

Clauses to invoke when an **OVER** clause references this window.

If the window definition omits a [window order clause](#), the **OVER** clause can specify its own order clause.

Requirements

- A **WINDOW** clause cannot include a [window frame clause](#).
- Each **WINDOW** clause within the same query must have a unique name.
- A **WINDOW** clause can reference another window that is already named. For example, the following query names window **w1** before **w2**. Thus, the **WINDOW** clause that defines **w2** can reference **w1**:

```
=> SELECT RANK() OVER(w1 ORDER BY sal DESC), RANK() OVER w2
FROM EMP WINDOW w1 AS (PARTITION BY deptno), w2 AS (w1 ORDER BY sal);
```

Examples

See [Named windows](#).

[Analytic functions](#).

## Data types

The following table summarizes the internal data types that Vertica supports. It also shows the default placement of null values in projections. The Size column lists uncompressed bytes.

Data Type	Size / bytes	Description	NULL Sorting
<b>Binary</b>			
BINARY	1 to 65,000	Fixed-length binary string	NULLS LAST
VARBINARY (synonyms: BYTEA , RAW )	1 to 65,000	Variable-length binary string	NULLS LAST
LONG VARBINARY	1 to 32,000,000	Long variable-length binary string	NULLS LAST
<b>Boolean</b>			

BOOLEAN	1	True or False or NULL	NULLS LAST
<b><a href="#">Character / Long</a></b>			
CHAR	1 to 65,000	Fixed-length character string	NULLS LAST
VARCHAR	1 to 65,000	Variable-length character string	NULLS LAST
LONG VARCHAR	1 to 32,000,000	Long variable-length character string	NULLS LAST
<b><a href="#">Date/Time</a></b>			
DATE	8	A month, day, and year	NULLS FIRST
TIME	8	A time of day without timezone	NULLS FIRST
TIME WITH TIMEZONE	8	A time of day with timezone	NULLS FIRST
TIMESTAMP (synonyms: DATETIME , SMALLDATETIME )	8	A date and time without timezone	NULLS FIRST
TIMESTAMP WITH TIMEZONE	8	A date and time with timezone	NULLS FIRST
INTERVAL	8	The difference between two points in time	NULLS FIRST
INTERVAL DAY TO SECOND	8	An interval measured in days and seconds	NULLS FIRST
INTERVAL YEAR TO MONTH	8	An interval measured in years and months	NULLS FIRST
<b><a href="#">Approximate Numeric</a></b>			
DOUBLE PRECISION	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
FLOAT	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
FLOAT(n)	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
FLOAT8	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
REAL	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
<b><a href="#">Exact Numeric</a></b>			
INTEGER	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
INT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
BIGINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
INT8	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
SMALLINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST

TINYINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
DECIMAL	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
NUMERIC	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
NUMBER	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
MONEY	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
<b>Spatial</b>			
GEOMETRY	1 to 10,000,000	Coordinates expressed as ( <i>x</i> , <i>y</i> ) pairs, defined in the Cartesian plane.	NULLS LAST
GEOGRAPHY	1 to 10,000,000	Coordinates expressed in longitude/latitude angular values, measured in degrees	NULLS LAST
<b>UUID</b>			
UUID	16	Stores universally unique identifiers (UUIDs).	NULLS FIRST
<b>Complex</b>			
ARRAY	1 to 32,000,000	Collection of values of a primitive or complex type.	Native array: same as the element type Non-native array: cannot be used to order projections
ROW	1 to 32,000,000	Structure of property-value pairs.	Cannot be used to order projections
SET	1 to 32,000,000	Collection of unique values of a primitive type.	Same as the primitive type

### Binary data types (BINARY and VARBINARY)

Store raw-byte data, such as IP addresses, up to 65000 bytes. The BINARY and BINARY VARYING ( VARBINARY ) data types are collectively referred to as *binary string types* and the values of binary string types are referred to as *binary strings* . A binary string is a sequence of octets or bytes.

BYTEA and RAW are synonyms for VARBINARY .

## Syntax

```
BINARY (length)
{ VARBINARY | BINARY VARYING | BYTEA | RAW } (max-length)
```

## Arguments

### **length** , **max-length**

The length of the string or column width, in bytes (octets).

## BINARY and VARBINARY data types

BINARY and VARBINARY data types have the following attributes:

- **BINARY** : A fixed-width string of *length* bytes, where the number of bytes is declared as an optional specifier to the type. If *length* is omitted, the default is 1. Where necessary, values are right-extended to the full width of the column with the zero byte. For example:

```
=> SELECT TO_HEX('ab'::BINARY(4));
to_hex

61620000
```

- **VARBINARY** : A variable-width string up to a length of *max-length* bytes, where the maximum number of bytes is declared as an optional specifier to the type. The default is the default attribute size, which is 80, and the maximum length is 65000 bytes. VARBINARY values are not extended to the full width of the column. For example:

```
=> SELECT TO_HEX('ab'::VARBINARY(4));
to_hex

6162
```

## Input formats

You can use several formats when working with binary values. The hexadecimal format is generally the most straightforward and is emphasized in Vertica documentation.

Binary values can also be represented in octal format by prefixing the value with a backslash `\`.

### Note

If you use `vsq`, you must use the escape character (`\`) when you insert another backslash on input; for example, input `'\141'` as `'\\141'`.

You can also input values represented by printable characters. For example, the hexadecimal value `'0x61'` can also be represented by the symbol `a`.

See [Data load](#).

On input, strings are translated from:

- Hexadecimal representation to a binary value using the function [HEX\\_TO\\_BINARY](#).
- [Bitstring](#) representation to a binary value using the function [BITSTRING\\_TO\\_BINARY](#).

Both functions take a VARCHAR argument and return a VARBINARY value.

## Output formats

Like the input format, the output format is a hybrid of octal codes and printable ASCII characters. A byte in the range of printable ASCII characters (the range `[0x20, 0x7e]`) is represented by the corresponding ASCII character, with the exception of the backslash (`\`), which is escaped as `\\`. All other byte values are represented by their corresponding octal values. For example, the bytes {97,92,98,99}, which in ASCII are {`a,\,b,c`}, are translated to text as `'a\bc'`.

## Binary operators and functions

The binary operators `&`, `~`, `|`, and `#` have special behavior for binary data types, as described in [Bitwise operators](#).

The following aggregate functions are supported for binary data types:

- [BIT\\_AND](#)
- [BIT\\_OR](#)
- [BIT\\_XOR](#)
- [MAX](#)
- [MIN](#)

BIT\_AND , BIT\_OR , and BIT\_XOR are bit-wise operations that are applied to each non-null value in a group, while MAX and MIN are byte-wise comparisons of binary values.

Like their [binary operator](#) counterparts, if the values in a group vary in length, the aggregate functions treat the values as though they are all equal in length by extending shorter values with zero bytes to the full width of the column. For example, given a group containing the values 'ff', null, and 'f' , a binary aggregate ignores the null value and treats the value 'f' as 'f0' . Also, like their binary operator counterparts, these aggregate functions operate on VARBINARY types explicitly and operate on BINARY types implicitly through casts. See [Data type coercion operators \(CAST\)](#).

#### Binary versus character data types

The BINARY and VARBINARY binary types are similar to the CHAR and VARCHAR [character data types](#), respectively. They differ as follows:

- Binary data types contain byte strings (a sequence of octets or bytes).
- Character data types contain character strings (text).
- The lengths of binary data types are measured in bytes, while character data types are measured in characters.

#### Examples

The following example shows [HEX\\_TO\\_BINARY](#) and [TO\\_HEX](#) usage.

Table `t` and its projection are created with binary columns:

```
=> CREATE TABLE t (c BINARY(1));
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

Insert minimum byte and maximum byte values:

```
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
```

Binary values can then be formatted in hex on output using the `TO_HEX` function:

```
=> SELECT TO_HEX(c) FROM t;
to_hex

00
ff
(2 rows)
```

The `BIT_AND` , `BIT_OR` , and `BIT_XOR` functions are interesting when operating on a group of values. For example, create a sample table and projections with binary columns:

The example that follows uses table `t` with a single column of `VARBINARY` data type:

```
=> CREATE TABLE t (c VARBINARY(2));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table `t` to see column `c` output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX

ff00
ffff
f00f
(3 rows)
```

Now issue the bitwise AND operation. Because these are aggregate functions, an implicit GROUP BY operation is performed on results using `(ff00&(ffff)&f00f)` :

```
=> SELECT TO_HEX(BIT_AND(c)) FROM t;
TO_HEX

f000
(1 row)
```

Issue the bitwise OR operation on `(ff00|(ffff)|f00f)` :

```
=> SELECT TO_HEX(BIT_OR(c)) FROM t;
TO_HEX

ffff
(1 row)
```

Issue the bitwise XOR operation on `(ff00#(ffff)#f00f)` :

```
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
TO_HEX

f0f0
(1 row)
```

## Boolean data type

Vertica provides the standard SQL type `BOOLEAN`, which has two states: true and false. The third state in SQL boolean logic is unknown, which is represented by the `NULL` value.

### Syntax

```
BOOLEAN
```

### Parameters

Valid literal data values for input are:

<code>TRUE</code>	<code>'t'</code>	<code>'true'</code>	<code>'y'</code>	<code>'yes'</code>	<code>'1'</code>	1
<code>FALSE</code>	<code>'f'</code>	<code>'false'</code>	<code>'n'</code>	<code>'no'</code>	<code>'0'</code>	0

### Notes

- Do not confuse the `BOOLEAN` data type with [Logical operators](#) or the [Boolean](#).
- The keywords `TRUE` and `FALSE` are preferred and are SQL-compliant.
- A Boolean value of `NULL` appears last (largest) in ascending order.
- All other values must be enclosed in single quotes.
- Boolean values are output using the letters t and f.

### See also

- [NULL value](#)
- [Data type coercion chart](#)

## Character data types (CHAR and VARCHAR)

Stores strings of letters, numbers, and symbols. The `CHARACTER ( CHAR )` and `CHARACTER VARYING ( VARCHAR )` data types are collectively referred to as *character string types*, and the values of character string types are known as *character strings*.

Character data can be stored as fixed-length or variable-length strings. Fixed-length strings are right-extended with spaces on output; variable-length strings are not extended.

String literals in SQL statements must be enclosed in single quotes.

### Syntax

```
{ CHAR | CHARACTER } [(octet-length)]
{ VARCHAR | CHARACTER VARYING } [(octet-length)]
```

### Arguments

#### `octet-length`

Length of the string or column width, declared in bytes (octets).

This argument is optional.

## CHAR versus VARCHAR data types

The following differences apply to CHAR and VARCHAR data:

- CHAR is conceptually a fixed-length, blank-padded string. Trailing blanks (spaces) are removed on input and are restored on output. The default length is 1, and the maximum length is 65000 octets (bytes).
- VARCHAR is a variable-length character data type. The default length is 80, and the maximum length is 65000 octets. For string values longer than 65000, use [Long data types](#). Values can include trailing spaces.

Normally, you use VARCHAR for all of string data. Use CHAR when you need fixed-width string output. For example, you can use CHAR columns for data to be transferred to a legacy system that requires fixed-width strings.

#### Setting maximum length

When you define character columns, specify the maximum size of any string to be stored in a column. For example, to store strings up to 24 octets in length, use one of the following definitions:

```
CHAR(24) --- fixed-length
VARCHAR(24) --- variable-length
```

The maximum length parameter for VARCHAR and CHAR data types refers to the number of octets that can be stored in that field, not the number of characters (Unicode code points). When using multibyte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 octets per character, depending on the data. If the data loaded into a VARCHAR or CHAR column exceeds the specified maximum size for that column, data is truncated on UTF-8 character boundaries to fit within the specified size. See [COPY](#).

#### Note

Remember to include the extra octets required for multibyte characters in the column-width declaration, keeping in mind the 65000 octet column-width limit.

Due to compression in Vertica, the cost of overestimating the length of these fields is incurred primarily at load time and during sorts.

#### NULL versus NUL

NULL and NUL differ as follows:

- NUL represents a character whose ASCII/Unicode code is 0, sometimes qualified "ASCII NUL".
- NULL means no value, and is true of a field (column) or constant, not of a character.

CHAR, LONG VARCHAR, and VARCHAR string data types accept ASCII NUL values.

In ascending sorts, NULL appears last (largest).

For additional information about NULL ordering, see [NULL sort order](#).

The following example casts the input string containing NUL values to VARCHAR :

```
=> SELECT 'vert\0ica'::CHARACTER VARYING AS VARCHAR;
VARCHAR

vert\0ica
(1 row)
```

The result contains 9 characters:

```
=> SELECT LENGTH('vert\0ica'::CHARACTER VARYING);
length

9
(1 row)
```

If you use an [extended string literal](#), the length is 8 characters:

```

=> SELECT E'vert\0ica'::CHARACTER VARYING AS VARCHAR;
VARCHAR

vertica
(1 row)
=> SELECT LENGTH(E'vert\0ica'::CHARACTER VARYING);
LENGTH

 8
(1 row)

```

## Date/time data types

Vertica supports the full set of SQL date and time data types.

The following rules apply to all date/time data types:

- All have a size of 8 bytes.
- A date/time value of NULL is smallest relative to all other date/time values,.
- Vertica uses Julian dates for all date/time calculations, which can correctly predict and calculate any date more recent than 4713 BC to far into the future, based on the assumption that the average length of the year is 365.2425 days.
- All the date/time data types accept the special literal value **NOW** to specify the current date and time. For example:

```

=> SELECT TIMESTAMP 'NOW';
?column?

2020-09-23 08:23:50.42325
(1 row)

```

- By default, Vertica rounds with a maximum precision of six decimal places. You can substitute an integer between 0 and 6 for **p** to [specify your preferred level of precision](#).

The following table lists specific attributes of date/time data types:

Name	Description	Low Value	High Value	Resolution
<a href="#">DATE</a>	Dates only (no time of day)	~ 25e+15 BC	~ 25e+15 AD	1 day
<a href="#">TIME [(p)]</a>	Time of day only (no date)	00:00:00.00	23:59:60.999999	1 μs
<a href="#">TIMETZ [(p)]</a>	Time of day only, with time zone	00:00:00.00+14	23:59:59.999999-14	1 μs
<a href="#">TIMESTAMP [(p)]</a>	Both date and time, without time zone	290279-12-22 19:59:05.224194 BC	294277-01-09 04:00:54.775806 AD	1 μs
<a href="#">TIMESTAMPTZ [(p)]*</a>	Both date and time, with time zone	290279-12-22 19:59:05.224194 BC UTC	294277-01-09 04:00:54.775806 AD UTC	1 μs
<a href="#">INTERVAL DAY TO SECOND [(p)]</a>	Time intervals	-106751991 days 04:00:54.775807	+106751991 days 04:00:54.775807	1 μs
<a href="#">INTERVAL YEAR TO MONTH</a>	Time intervals	~ -768e15 yrs	~ 768e15 yrs	1 month

### Time zone abbreviations for input

Vertica recognizes the files in [/opt/vertica/share/timezonesets](#) as date/time input values and defines the default list of strings accepted in the AT TIME ZONE *zone* parameter. The names are not necessarily used for date/time output—output is driven by the official time zone abbreviations associated with the currently selected time zone parameter setting.

In this section

- [DATE](#)

- [DATETIME](#)
- [INTERVAL](#)
- [SMALLDATETIME](#)
- [TIME/TIMETZ](#)
- [TIME AT TIME\\_ZONE](#)
- [TIMESTAMP/TIMESTAMPZ](#)
- [TIMESTAMP AT TIME\\_ZONE](#)

## DATE

Consists of a month, day, and year. The following limits apply:

- Lowest value: ~ 25e+15 BC
- Highest value: ~ 25e+15 AD
- Resolution: 1 DAY

See [SET DATESTYLE](#) for information about ordering.

### Note

'0000-00-00' is not valid. If you try to insert that value into a DATE or TIMESTAMP field, an error occurs. If you copy '0000-00-00' into a DATE or TIMESTAMP field, Vertica converts the value to 0001-01-01 00:00:00 BC.

## Syntax

DATE

## Examples

Example	Description
January 8, 1999	Unambiguous in any <code>datestyle</code> input mode
1999-01-08	ISO 8601; January 8 in any mode (recommended format)
1/8/1999	January 8 in <code>MDY</code> mode; August 1 in <code>DMY</code> mode
1/18/1999	January 18 in <code>MDY</code> mode; rejected in other modes
01/02/03	January 2, 2003 in <code>MDY</code> mode February 1, 2003 in <code>DMY</code> mode February 3, 2001 in <code>YMD</code> mode
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in <code>YMD</code> mode, else error
08-Jan-99	January 8, except error in <code>YMD</code> mode
Jan-08-99	January 8, except error in <code>YMD</code> mode
19990108	ISO 8601; January 8, 1999 in any mode
990108	ISO 8601; January 8, 1999 in any mode
1999.008	Year and day of year

J2451187	Julian day
January 8, 99 BC	Year 99 before the Common Era

## DATETIME

DATETIME is an alias for [TIMESTAMP/TIMESTAMPTZ](#).

## INTERVAL

Measures the difference between two points in time. Intervals can be positive or negative. The **INTERVAL** data type is SQL:2008 compliant, and supports [interval qualifiers](#) that are divided into two major subtypes:

- [Year-month](#): Span of years and months
- [Day-time](#): Span of days, hours, minutes, seconds, and fractional seconds

Intervals are represented internally as some number of microseconds and printed as up to 60 seconds, 60 minutes, 24 hours, 30 days, 12 months, and as many years as necessary. You can [control the output format](#) of interval units with [SET INTERVALSTYLE](#) and [SET DATESTYLE](#).

### Syntax

```
INTERVAL 'interval-literal' [interval-qualifier] [(p)]
```

### Parameters

#### [interval-literal](#)

A character string that expresses an interval, conforming to this format:

```
[-] { quantity subtype-unit } [...] [AGO]
```

For details, see [Interval literal](#).

#### [interval-qualifier](#)

Optionally specifies how to interpret and format an interval literal for output, and, optionally, sets precision. If omitted, the default is **DAY TO SECOND(6)**. For details, see [Interval qualifier](#).

#### *p*

Specifies precision of the seconds field, where *p* is an integer between 0 - 6. For details, see [Specifying interval precision](#).

**Default:** 6

### Limits

Name	Low Value	High Value	Resolution
INTERVAL DAY TO SECOND [( <i>p</i> )]	-106751991 days 04:00:54.775807	+/-106751991 days 04:00:54.775807	1 microsecond
INTERVAL YEAR TO MONTH	~/ -768e15 yrs	~ 768e15 yrs	1 month

### In this section

- [Setting interval unit display](#)
- [Specifying interval input](#)
- [Controlling interval format](#)
- [Specifying interval precision](#)
- [Fractional seconds in interval units](#)
- [Processing signed intervals](#)
- [Casting with intervals](#)
- [Operations with intervals](#)

### Setting interval unit display

[SET INTERVALSTYLE](#) and [SET DATESTYLE](#) control the output format of interval units.

### Important

DATESTYLE settings supersede INTERVALSTYLE. If DATESTYLE is set to SQL, interval unit display always conforms to the SQL:2008 standard, which omits interval unit display. If DATESTYLE is set to ISO, you can use [SET INTERVALSTYLE](#) to omit or display interval unit display, as described below.

### Omitting interval units

To omit interval units from the output, set `INTERVALSTYLE` to `PLAIN`. This is the default setting, which conforms with the SQL:2008 standard:

```
=> SET INTERVALSTYLE TO PLAIN;
SET
=> SELECT INTERVAL '3 2';
?column?

3 02:00
```

When `INTERVALSTYLE` is set to `PLAIN`, units are omitted from the output, even if the query specifies input units:

```
=> SELECT INTERVAL '3 days 2 hours';
?column?

3 02:00
```

If `DATESTYLE` is set to `SQL`, Vertica conforms with SQL:2008 standard and always omits interval units from output:

```
=> SET DATESTYLE TO SQL;
SET
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT INTERVAL '3 2';
?column?

3 02:00
```

### Displaying interval units

To enable display of interval units, `DATESTYLE` must be set to `ISO`. You can then display interval units by setting `INTERVALSTYLE` to `UNITS`:

```
=> SET DATESTYLE TO ISO;
SET
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT INTERVAL '3 2';
?column?

3 days 2 hours
```

### Checking INTERVALSTYLE and DATESTYLE settings

Use `SHOW` statements to check `INTERVALSTYLE` and `DATESTYLE` settings:

```
=> SHOW INTERVALSTYLE;
 name | setting
-----+-----
intervalstyle | units
=> SHOW DATESTYLE;
 name | setting
-----+-----
datestyle | ISO, MDY
```

### Specifying interval input

Interval values are expressed through [interval literals](#). An interval literal is composed of one or more interval fields, where each field represents a span of days and time, or years and months, as follows:

```
[-] { quantity subtype-unit } [...] [AGO]
```

### Using subtype units

Subtype units are optional for [day-time](#) intervals; they must be specified for [year-month](#) intervals.

For example, the first statement below implicitly specifies days and time; the second statement explicitly identifies day and time units. Both statements return the same result:

```
=> SET INTERVALSTYLE TO UNITS;
=> SELECT INTERVAL '1 12:59:10:05';
 ?column?

1 day 12:59:10.005
(1 row)

=> SELECT INTERVAL '1 day 12 hours 59 min 10 sec 5 milliseconds';
 ?column?

1 day 12:59:10.005
(1 row)
```

The following two statements add 28 days and 4 weeks to the current date, respectively. The intervals in both cases are equal and the statements return the same result. However, in the first statement, the interval literal omits the subtype (implicitly [days](#) ); in the second statement, the interval literal must include the subtype unit [weeks](#) :

```
=> SELECT CURRENT_DATE;
 ?column?

2016-08-15
(1 row)

=> SELECT CURRENT_DATE + INTERVAL '28';
 ?column?

2016-09-12 00:00:00
(1 row)

dbadmin=> SELECT CURRENT_DATE + INTERVAL '4 weeks';
 ?column?

2016-09-12 00:00:00
(1 row)
```

An interval literal can include day-time and year-month fields. For example, the following statement adds an interval of 4 years, 4 weeks, 4 days and 14 hours to the current date. The years and weeks fields must include subtype units; the days and hours fields omit them:

```
> SELECT CURRENT_DATE + INTERVAL '4 years 4 weeks 4 14';
 ?column?

2020-09-15 14:00:00
(1 row)
```

#### Omitting subtype units

You can specify quantities of days, hours, minutes, and seconds without specifying units. Vertica recognizes colons in interval literals as part of the timestamp:

```
=> SELECT INTERVAL '1 4 5 6';
```

```
?column?
```

```

1 day 04:05:06
```

```
=> SELECT INTERVAL '1 4:5:6';
```

```
?column?
```

```

1 day 04:05:06
```

```
=> SELECT INTERVAL '1 day 4 hour 5 min 6 sec';
```

```
?column?
```

```

1 day 04:05:06
```

If Vertica cannot determine the units, it applies the quantity to any missing units based on the interval qualifier. In the next two examples, Vertica uses the default interval qualifier ( [DAY TO SECOND\(6\)](#) ) and assigns the trailing **1** to days, since it has already processed hours, minutes, and seconds in the output:

```
=> SELECT INTERVAL '4:5:6 1';
```

```
?column?
```

```

1 day 04:05:06
```

```
=> SELECT INTERVAL '1 4:5:6';
```

```
?column?
```

```

1 day 04:05:06
```

In the next two examples, Vertica recognizes **4:5** as **hours:minutes** . The remaining values in the interval literal are assigned to the missing units: **1** is assigned to days and **2** is assigned to seconds.

```
SELECT INTERVAL '4:5 1 2';
```

```
?column?
```

```

1 day 04:05:02
```

```
=> SELECT INTERVAL '1 4:5 2';
```

```
?column?
```

```

1 day 04:05:02
```

Specifying the interval qualifier can change how Vertica interprets **4:5** :

```
=> SELECT INTERVAL '4:5' MINUTE TO SECOND;
```

```
?column?
```

```

00:04:05
```

### Controlling interval format

[Interval qualifiers](#) specify a range of options that Vertica uses to interpret and format an [interval literal](#) . The interval qualifier can also specify precision. Each interval qualifier is composed of one or two units:

```
unit[p] [TO unit[p]]
```

where:

- *unit* specifies a day-time or year-month [subtype](#) .
- *p* specifies precision, an integer between 0 and 6. In general, precision only applies to **SECOND** units. The default precision for **SECOND** is 6. For details, see [Specifying interval precision](#) .

If an interval omits an interval qualifier, Vertica uses the default [DAY TO SECOND\(6\)](#) .

### Interval qualifier categories

Interval qualifiers belong to one of the following categories:

- [Year-month](#) : Span of years and months

- [Day-time](#): Span of days, hours, minutes, seconds, and fractional seconds

#### Note

All examples below assume that [INTERVALSTYLE](#) is set to plain.

#### Year-Month

Vertica supports two year-month subtypes: [YEAR](#) and [MONTH](#).

In the following example, [YEAR TO MONTH](#) qualifies the interval literal `1 2` to indicate a span of 1 year and two months:

```
=> SELECT interval '1 2' YEAR TO MONTH;
?column?

1-2
(1 row)
```

If you omit the qualifier, Vertica uses the default interval qualifier [DAY TO SECOND](#) and returns a different result:

```
=> SELECT interval '1 2';
?column?

1 02:00
(1 row)
```

The following example uses the interval qualifier [YEAR](#). In this case, Vertica extracts only the year from the interval literal `1y 10m`:

```
=> SELECT INTERVAL '1y 10m' YEAR;
?column?

1
(1 row)
```

In the next example, the interval qualifier [MONTH](#) converts the same interval literal to months:

```
=> SELECT INTERVAL '1y 10m' MONTH;
?column?

22
(1 row)
```

#### Day-time

Vertica supports four day-time subtypes: [DAY](#), [HOUR](#), [MINUTE](#), and [SECOND](#).

In the following example, the interval qualifier [DAY TO SECOND\(4\)](#) qualifies the interval literal `1h 3m 6s 5msecs 57us`. The qualifier also sets precision on seconds to 4:

```
=> SELECT INTERVAL '1h 3m 6s 5msecs 57us' DAY TO SECOND(4);
?column?

01:03:06.0051
(1 row)
```

If no interval qualifier is specified, Vertica uses the default subtype [DAY TO SECOND\(6\)](#), regardless of how you specify the interval literal. For example, as an extension to SQL:2008, both of the following commands return `910 days`:

```
=> SELECT INTERVAL '2-6';
?column?
```

```

910
```

```
=> SELECT INTERVAL '2 years 6 months';
?column?
```

```

910
```

An interval qualifier can extract other values from the input parameters. For example, the following command extracts the **HOUR** value from the interval literal **3 days 2 hours** :

```
=> SELECT INTERVAL '3 days 2 hours' HOUR;
?column?
```

```

74
```

The primary day/time ( **DAY TO SECOND** ) and year/month ( **YEAR TO MONTH** ) subtype ranges can be restricted to more specific range of types by an interval qualifier. For example, **HOUR TO MINUTE** is a limited form of day/time interval, which can be used to express time zone offsets.

```
=> SELECT INTERVAL '1 3' HOUR to MINUTE;
?column?
```

```

01:03
```

**hh:mm:ss** and **hh:mm** formats are used only when at least two of the fields specified in the interval qualifier are non-zero and there are no more than 23 hours or 59 minutes:

```
=> SELECT INTERVAL '2 days 12 hours 15 mins' DAY TO MINUTE;
?column?
```

```

2 12:15
```

```
=> SELECT INTERVAL '15 mins 20 sec' MINUTE TO SECOND;
?column?
```

```

15:20
```

```
=> SELECT INTERVAL '1 hour 15 mins 20 sec' MINUTE TO SECOND;
?column?
```

```

75:20
```

### Specifying interval precision

In general, interval precision only applies to seconds. If no precision is explicitly specified, Vertica rounds precision to a maximum of six decimal places. For example:

```
=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;
?column?
```

```

02:04:03.709385
```

```
(1 row)
```

Vertica lets you specify interval precision in two ways:

- After the **INTERVAL** keyword
- After the **SECOND** unit of an interval qualifier, one of the following:
  - **DAY TO SECOND**
  - **HOUR TO SECOND**
  - **MINUTE TO SECOND**
  - **SECOND**

For example, the following statements use both methods to set precision, and return identical results:

```
=> SELECT INTERVAL(4) '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;
?column?

02:04:03.7094
(1 row)

=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND(4);
?column?

02:04:03.7094
(1 row)
```

If the same statement specifies precision more than once, Vertica uses the lesser precision. For example, the following statement specifies precision twice: the **INTERVAL** keyword specifies precision of 1, while the interval qualifier **SECOND** specifies precision of 2. Vertica uses the lesser precision of 1:

```
=> SELECT INTERVAL(1) '1.2467' SECOND(2);
?column?

1.2 secs
```

#### Setting precision on interval table columns

If you create a table with an interval column, the following restrictions apply to the column definition:

- You can set precision on the **INTERVAL** keyword only if you omit specifying an interval qualifier. If you try to set precision on the **INTERVAL** keyword and include an interval qualifier, Vertica returns an error.
- You can set precision only on the last unit of an interval qualifier. For example:

```
CREATE TABLE public.testint2
(
 i INTERVAL HOUR TO SECOND(3)
);
```

If you specify precision on another unit, Vertica discards it when it saves the table definition.

#### Fractional seconds in interval units

Vertica supports intervals in milliseconds (hh:mm:ss:ms), where **01:02:03:25** represents 1 hour, 2 minutes, 3 seconds, and 025 milliseconds. Milliseconds are converted to fractional seconds as in the following example, which returns 1 day, 2 hours, 3 minutes, 4 seconds, and 25.5 milliseconds:

```
=> SELECT INTERVAL '1 02:03:04:25.5';
?column?

1 day 02:03:04.0255
```

Vertica allows fractional minutes. The fractional minutes are rounded into seconds:

```
=> SELECT INTERVAL '10.5 minutes';
?column?

00:10:30
=> select interval '10.659 minutes';
?column?

00:10:39.54
=> select interval '10.33333333333333 minutes';
?column?

00:10:20
```

#### Considerations

- An **INTERVAL** can include only the subset of units that you need; however, year/month intervals represent calendar years and months with no fixed number of days, so year/month interval values cannot include days, hours, minutes. When year/month values are specified for day/time intervals, the intervals extension assumes 30 days per month and 365 days per year. Since the length of a given month or year varies, day/time intervals are never output as months or years, only as days, hours, minutes, and so on.
- Day/time and year/month intervals are logically independent and cannot be combined with or compared to each other. In the following example, an interval-literal that contains **DAYS** cannot be combined with the **YEAR TO MONTH** type:

```
=> SELECT INTERVAL '1 2 3' YEAR TO MONTH;
ERROR 3679: Invalid input syntax for interval year to month: "1 2 3"
```

- Vertica accepts intervals up to  $2^{63} - 1$  microseconds or months (about 18 digits).
- **INTERVAL YEAR TO MONTH** can be used in an analytic **RANGE window** when the **ORDER BY** column type is **TIMESTAMP/TIMESTAMP WITH TIMEZONE**, or **DATE**. Using **TIME/TIME WITH TIMEZONE** are not supported.
- You can use **INTERVAL DAY TO SECOND** when the **ORDER BY** column type is **TIMESTAMP/TIMESTAMP WITH TIMEZONE**, **DATE**, and **TIME/TIME WITH TIMEZONE**.

## Examples

Examples in this section assume that **INTERVALSTYLE** is set to **PLAIN**, so results omit [subtype units](#). Interval values that omit an [interval qualifier](#) use the default to **DAY TO SECOND(6)**.

```
=> SELECT INTERVAL '00:2500:00';
?column?

1 17:40
(1 row)

=> SELECT INTERVAL '2500' MINUTE TO SECOND;
?column?

2500
(1 row)

=> SELECT INTERVAL '2500' MINUTE;
?column?

2500
(1 row)

=> SELECT INTERVAL '28 days 3 hours' HOUR TO SECOND;
?column?

675:00
(1 row)

=> SELECT INTERVAL(3) '28 days 3 hours';
?column?

28 03:00
(1 row)

=> SELECT INTERVAL(3) '28 days 3 hours 1.234567';
?column?

28 03:01:14.074
(1 row)

=> SELECT INTERVAL(3) '28 days 3 hours 1.234567 sec';
?column?

28 03:00:01.235
(1 row)

SELECT INTERVAL(3) '28 days 3 hours' HOUR TO SECOND;
```

```
=> SELECT INTERVAL(3) '28 days 3.3 hours' HOUR TO SECOND;
?column?
```

```

675:18
(1 row)
```

```
=> SELECT INTERVAL(3) '28 days 3.35 hours' HOUR TO SECOND;
?column?
```

```

675:21
(1 row)
```

```
=> SELECT INTERVAL(3) '28 days 3.37 hours' HOUR TO SECOND;
?column?
```

```

675:22:12
(1 row)
```

```
=> SELECT INTERVAL '1.234567 days' HOUR TO SECOND;
?column?
```

```

29:37:46.5888
(1 row)
```

```
=> SELECT INTERVAL '1.23456789 days' HOUR TO SECOND;
?column?
```

```

29:37:46.665696
(1 row)
```

```
=> SELECT INTERVAL(3) '1.23456789 days' HOUR TO SECOND;
?column?
```

```

29:37:46.666
(1 row)
```

```
=> SELECT INTERVAL(3) '1.23456789 days' HOUR TO SECOND(2);
?column?
```

```

29:37:46.67
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' as "one hour+";
one hour+
```

```

01:00:01.235
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL(3) '01:00:01.234567';
?column?
```

```

t
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567';
?column?
```

```

f
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567'
HOUR TO SECOND(2);
```

```
FLOOR TO SECOND(3);
```

```
?column?
```

```
t
```

```
(1 row)
```

```
=> SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567'
```

```
MINUTE TO SECOND(3);
```

```
?column?
```

```
t
```

```
(1 row)
```

```
=> SELECT INTERVAL '255 1.1111' MINUTE TO SECOND(3);
```

```
?column?
```

```
255:01.111
```

```
(1 row)
```

```
=> SELECT INTERVAL '@ - 5 ago';
```

```
?column?
```

```
5
```

```
(1 row)
```

```
=> SELECT INTERVAL '@ - 5 minutes ago';
```

```
?column?
```

```
00:05
```

```
(1 row)
```

```
=> SELECT INTERVAL '@ 5 minutes ago';
```

```
?column?
```

```
-00:05
```

```
(1 row)
```

```
=> SELECT INTERVAL '@ ago -5 minutes';
```

```
?column?
```

```
00:05
```

```
(1 row)
```

```
=> SELECT DATE_PART('month', INTERVAL '2-3' YEAR TO MONTH);
```

```
DATE_PART
```

```
3
```

```
(1 row)
```

```
=> SELECT FLOOR((TIMESTAMP '2005-01-17 10:00'
```

```
- TIMESTAMP '2005-01-01')
```

```
/ INTERVAL '7');
```

```
FLOOR
```

```
2
```

```
(1 row)
```

In the SQL:2008 standard, a minus sign before an interval-literal or as the first character of the interval-literal negates the entire literal, not just the first component. In Vertica, a leading minus sign negates the entire interval, not just the first component. The following commands both return the same value:

```
=> SELECT INTERVAL '-1 month - 1 second';
?column?

-29 days 23:59:59

=> SELECT INTERVAL '-1 month - 1 second';
?column?

-29 days 23:59:59
```

Use one of the following commands instead to return the intended result:

```
=> SELECT INTERVAL '-1 month 1 second';
?column?

-30 days 1 sec

=> SELECT INTERVAL '-30 00:00:01';
?column?

-30 days 1 sec
```

Two negatives together return a positive:

```
=> SELECT INTERVAL '--1 month - 1 second';
?column?

29 days 23:59:59

=> SELECT INTERVAL '--1 month 1 second';
?column?

30 days 1 sec
```

You can use the year-month syntax with no spaces. Vertica allows the input of negative months but requires two negatives when paired with years.

```
=> SELECT INTERVAL '3-3' YEAR TO MONTH;
?column?

3 years 3 months

=> SELECT INTERVAL '3--3' YEAR TO MONTH;
?column?

2 years 9 months
```

When the interval-literal looks like a year/month type, but the type is day/second, or vice versa, Vertica reads the interval-literal from left to right, where number-number is years-months, and number <space> <signed number> is whatever the units specify. Vertica processes the following command as  $(-)$  1 year 1 month =  $(-)$  365 + 30 = -395 days:

```
=> SELECT INTERVAL '-1-1' DAY TO HOUR;
?column?

-395 days
```

If you insert a space in the interval-literal, Vertica processes it based on the subtype **DAY TO HOUR** :  $(-)$  1 day - 1 hour =  $(-)$  24 - 1 = -23 hours:

```
=> SELECT INTERVAL '-1 -1' DAY TO HOUR;
?column?

-23 hours
```

Two negatives together returns a positive, so Vertica processes the following command as  $(-)$  1 year - 1 month =  $(-)$  365 - 30 = -335 days:

```
=> SELECT INTERVAL '-1--1' DAY TO HOUR;
?column?

-335 days
```

If you omit the value after the hyphen, Vertica assumes 0 months and processes the following command as 1 year 0 month -1 day = 365 + 0 - 1 = -364 days:

```
=> SELECT INTERVAL '1- -1' DAY TO HOUR;
?column?

364 days
```

### Casting with intervals

You can use **CAST** to convert strings to intervals, and vice versa.

#### String to interval

You cast a string to an interval as follows:

```
CAST([INTERVAL[(p)]] [-]] interval-literal AS INTERVAL[(p)] interval-qualifier)
```

For example:

```
=> SELECT CAST('3700 sec' AS INTERVAL);
?column?

01:01:40
```

You can cast intervals within day-time or the year-month subtypes but not between them:

```
=> SELECT CAST(INTERVAL '4440' MINUTE as INTERVAL);
?column?

3 days 2 hours
=> SELECT CAST(INTERVAL '-01:15' as INTERVAL MINUTE);
?column?

-75 mins
```

#### Interval to string

You cast an interval to a string as follows:

```
CAST((SELECT interval) AS VARCHAR[(n)])
```

For example:

```
=> SELECT CONCAT(
'Tomorrow at this time: ',
CAST((SELECT INTERVAL '24 hours') + CURRENT_TIMESTAMP(0) AS VARCHAR));
CONCAT

Tomorrow at this time: 2016-08-17 08:41:23-04
(1 row)
```

### Operations with intervals

If you divide an interval by an interval, you get a **FLOAT** :

```
=> SELECT INTERVAL '28 days 3 hours' HOUR(4) / INTERVAL '27 days 3 hours' HOUR(4);
?column?

1.036866359447
```

An **INTERVAL** divided by **FLOAT** returns an **INTERVAL** :

```
=> SELECT INTERVAL '3' MINUTE / 1.5;
?column?

2 mins
```

**INTERVAL MODULO** (remainder) **INTERVAL** returns an **INTERVAL** :

```
=> SELECT INTERVAL '28 days 3 hours' HOUR % INTERVAL '27 days 3 hours' HOUR;
?column?

24 hours
```

If you add **INTERVAL** and **TIME** , the result is **TIME** , modulo 24 hours:

```
=> SELECT INTERVAL '1' HOUR + TIME '1:30';
?column?

02:30:00
```

## SMALLDATETIME

SMALLDATETIME is an alias for [TIMESTAMP/TIMESTAMPTZ](#).

## TIME/TIMETZ

Stores the specified time of day. **TIMETZ** is the same as **TIME WITH TIME ZONE** : both data types store the UTC offset of the specified time.

### Syntax

```
TIME [(p)] [{ WITHOUT | WITH } TIME ZONE] 'input-string' [AT TIME ZONE zone]
```

### Parameters

#### *p*

Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.

#### **WITHOUT TIME ZONE**

Ignore any time zone in the input string and use a value without a time zone (default).

#### **WITH TIME ZONE**

Convert the time to UTC. If the input string includes a time zone, use its UTC offset for the conversion. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is [configured for your system](#).

#### *input-string*

See [Input String](#) below.

#### **AT TIME ZONE zone**

See [TIME AT TIME ZONE](#) and [TIMESTAMP AT TIME ZONE](#).

### TIMETZ vs. TIMESTAMPTZ

**TIMETZ** and [TIMESTAMPTZ](#) are not parallel SQL constructs. **TIMESTAMPTZ** records a time and date in GMT, converting from the specified **TIME ZONE**. **TIMETZ** records the specified time and the specified time zone, in minutes, from GMT.

### Limits

Name	Low Value	High Value	Resolution
TIME [ p ]	00:00:00.00	23:59:60.999999	1 μs
TIME [ p ] WITH TIME ZONE	00:00:00.00+14	23:59:59.999999-14	1 μs

### Input string

A **TIME** input string can be set to any of the formats shown below:

Example	Description
---------	-------------

04:05:06.789	ISO 8601
04:05:06	ISO 8601
04:05	ISO 8601
040506	ISO 8601
04:05 AM	Same as 04:05; AM does not affect value
04:05 PM	Same as 16:05
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	Time zone specified by name

#### Data type coercion

You can cast a **TIME** or **TIMETZ** interval to a **TIMESTAMP** . This returns the local date and time as follows:

```
=> SELECT (TIME '3:01am')::TIMESTAMP;
?column?
```

```

2012-08-30 03:01:00
(1 row)
```

```
=> SELECT (TIMETZ '3:01am')::TIMESTAMP;
?column?
```

```

2012-08-22 03:01:00
(1 row)
```

Casting the same **TIME** or **TIMETZ** interval to a **TIMESTAMPTZ** returns the local date and time, appended with the UTC offset—in this example, **-05** :

```
=> SELECT (TIME '3:01am')::TIMESTAMPTZ;
?column?
```

```

2016-12-08 03:01:00-05
(1 row)
```

#### TIME AT TIME ZONE

Converts the specified **TIME** to the time in another time zone.

#### Syntax

```
TIME [WITH TIME ZONE] 'input-string' AT TIME ZONE 'zone'
```

#### Parameters

##### WITH TIME ZONE

Converts the input string to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is [configured for your system](#), and converts the input string accordingly

##### zone

Specifies the time zone to use in the conversion, either as a literal or interval that specifies UTC offset:

- **AT TIME ZONE INTERVAL 'utc-offset'**

- `AT TIME ZONE 'time-zone-literal'`

For details, see [Specifying Time Zones](#) below.

#### Note

Vertica treats literals `TIME ZONE` and `TIMEZONE` as synonyms.

### Specifying time zones

You can specify time zones in two ways:

- A string literal such as `America/Chicago` or `PST`
- An interval that specifies a UTC offset—for example, `INTERVAL '-08:00'`

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is `-04`, both queries return the same results:

```
=> SELECT CURRENT_TIME(0) "EDT";
 EDT

12:34:35-04
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE 'America/Denver' "Mountain Time";
 Mountain Time

10:34:35-06
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
 Mountain Time

10:34:35-06
(1 row)
```

If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to `-07`—otherwise, Vertica returns a different (and erroneous) result:

```
=> SELECT CURRENT_TIME(0) "EST";
 EST

14:18:22-05
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
 Mountain Time

13:18:22-06
(1 row)
```

You can show and set the session's time zone with [SHOW TIMEZONE](#) and [SET TIME ZONE](#), respectively:

```

=> SHOW TIMEZONE;
 name | setting
-----+-----
timezone | America/New_York
(1 row)

=> SELECT CURRENT_TIME(0) "Eastern Daylight Time";
Eastern Daylight Time

12:18:24-04
(1 row)

=> SET TIMEZONE 'America/Los_Angeles';
SET

=> SELECT CURRENT_TIME(0) "Pacific Daylight Time";
Pacific Daylight Time

09:18:24-07
(1 row)

```

#### Time zone literals

To view the default list of valid literals, see the files in the following directory:

```
opt/vertica/share/timezonesets
```

For example:

```

$ cat Antarctica.txt
...
src/timezone/tznames/Antarctica.txt
#
AWST 28800 # Australian Western Standard Time
 # (Antarctica/Casey)
 # (Australia/Perth)
...
NZST 43200 # New Zealand Standard Time
 # (Antarctica/McMurdo)
 # (Pacific/Auckland)
ROTT -10800 # Rothera Time
 # (Antarctica/Rothera)
SYOT 10800 # Syowa Time
 # (Antarctica/Syowa)
VOST 21600 # Vostok time
 # (Antarctica/Vostok)

```

#### Examples

The following example assumes that local time is EST (Eastern Standard Time). The query converts the specified time to MST (mountain standard time):

```
=> SELECT CURRENT_TIME(0);
```

```
timezone
```

```

10:10:56-05
```

```
(1 row)
```

```
=> SELECT TIME '10:10:56' AT TIME ZONE 'America/Denver' "Denver Time";
```

```
Denver Time
```

```

08:10:56-07
```

```
(1 row)
```

The next example adds a time zone literal to the input string—in this case, [Europe/Vilnius](#) —and converts the time to MST:

```
=> SELECT TIME '09:56:13 Europe/Vilnius' AT TIME ZONE 'America/Denver';
```

```
Denver Time
```

```

00:56:13-07
```

```
(1 row)
```

- [Sources for Time Zone and Daylight Saving Time Data](#)

## TIMESTAMP/TIMESTAMPTZ

Stores the specified date and time. **TIMESTAMPTZ** is the same as **TIMESTAMP WITH TIME ZONE** : both data types store the UTC offset of the specified time.

**TIMESTAMP** is an alias for **DATETIME** and **SMALLDATETIME** .

### Syntax

```
TIMESTAMP [(p)] [{ WITHOUT | WITH } TIME ZONE] 'input-string' [AT TIME ZONE zone]
```

```
TIMESTAMPTZ [(p)] 'input-string' [AT TIME ZONE zone]
```

### Parameters

#### **p**

Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.

#### **WITHOUT TIME ZONE**

#### **WITH TIME ZONE**

Specifies whether to include a time zone with the stored value:

- **WITHOUT TIME ZONE** (default): Specifies that *input-string* does not include a time zone. If the input string contains a time zone, Vertica ignores this qualifier. Instead, it conforms to **WITH TIME ZONE** behavior.
- **WITH TIME ZONE** : Specifies to convert *input-string* to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is [configured for your system](#) .

#### **input-string**

See [Input String](#) below.

#### **AT TIME ZONE zone**

See [TIMESTAMP AT TIME ZONE](#) .

### Limits

In the following table, values are rounded. See [Date/time data types](#) for more detail.

Name	Low Value	High Value	Resolution
<b>TIMESTAMP [ (p) ] [ WITHOUT TIME ZONE ]</b>	290279 BC	294277 AD	1 μs

TIMESTAMP [ (p) ] WITH TIME ZONE	290279 BC	294277 AD	1 μs
----------------------------------	-----------	-----------	------

Input string

The date/time input string concatenates a date and a time. The input string can include a time zone, specified as a literal such as `America/Chicago` , or as a UTC offset.

The following list represents typical date/time input variations:

- `1999-01-08 04:05:06`
- `1999-01-08 04:05:06 -8:00`
- `January 8 04:05:06 1999 PST`

#### Note

`0000-00-00` is invalid input. If you try to insert that value into a DATE or TIMESTAMP field, an error occurs. If you copy `0000-00-00` into a DATE or TIMESTAMP field, Vertica converts the value to `0001-01-01 00:00:00 BC` .

The input string can also specify the calendar era, either `AD` (default) or `BC` . If you omit the calendar era, Vertica assumes the current calendar era ( `AD` ). The calendar era typically follows the time zone; however, the input string can include it in various locations. For example, the following queries return the same results:

```
=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 CET BC ' "Caesar's Time of Death EST";
Caesar's Time of Death EST

0044-03-01 06:00:00-05 BC
(1 row)

=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 BC CET' "Caesar's Time of Death EST";
Caesar's Time of Death EST

0044-03-01 06:00:00-05 BC
(1 row)
```

#### Examples

```
=> SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01');
?column?

16 10:00
(1 row)

=> SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') / 7;
?column?

2 08:17:08.571429
(1 row)

=> SELECT TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28';
?column?

1 15:21:00.456789
(1 row)

=> SELECT (TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28')(3);
?column?

1 15:21:00.457
(1 row)

=> SELECT '2017-03-18 07:00'::TIMESTAMPTZ(0) + INTERVAL '1.5 day';
?column?
```

-----  
2017-03-19 19:00:00-04

(1 row)

=> SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') day;  
?column?

-----  
16

(1 row)

=> SELECT cast((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01')  
day as integer) / 7;  
?column?

-----  
2.285714285714285714

(1 row)

=> SELECT floor((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01')  
/ interval '7');  
floor

-----  
2

(1 row)

=> SELECT (TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28') second;  
?column?

-----  
141660.456789

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') year;  
?column?

-----  
3

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') month;  
?column?

-----  
40

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01')  
year to month;  
?column?

-----  
3-4

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01')  
second(3);  
?column?

-----  
107536860.457

(1 row)

=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') minute;  
?column?

-----  
1792281

(1 row)

```
=> SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01')
minute to second(3);
?column?

1792281:00.457
(1 row)
```

```
=> SELECT TIMESTAMP 'infinity';
?column?

infinity
(1 row)
```

## TIMESTAMP AT TIME ZONE

Converts the specified **TIMESTAMP** or **TIMESTAMPTZ** ( **TIMESTAMP WITH TIMEZONE** ) to another time zone. Vertica executes **AT TIME ZONE** differently, depending on whether the date input is a **TIMESTAMP** or **TIMESTAMPTZ** . See [TIMESTAMP versus TIMESTAMPTZ Behavior](#) below.

### Syntax

```
timestamp-clause AT TIME ZONE 'zone'
```

### Parameters

[\[timestamp-clause\]\(/sql-reference/data-types/datetime-data-types/timestamptimestampz.html\)](#)

Specifies the timestamp to convert, either **TIMESTAMP** or **TIMESTAMPTZ** .

For details, see [TIMESTAMP/TIMESTAMPTZ](#) .

### **AT TIME ZONE** *zone*

Specifies the time zone to use in the timestamp conversion, where *zone* is a literal or interval that specifies a UTC offset:

- **AT TIME ZONE INTERVAL** ' *utc-offset* '
- **AT TIME ZONE** ' *time-zone-literal* '

For details, see [Specifying Time Zones](#) below.

#### Note

Vertica treats literals **TIME ZONE** and **TIMEZONE** as synonyms.

## TIMESTAMP versus TIMESTAMPTZ behavior

How Vertica interprets **AT TIME ZONE** depends on whether the date input is a **TIMESTAMP** or **TIMESTAMPTZ** :

Date input	Action
------------	--------

## TIMESTAMP

If the input string specifies no time zone, Vertica performs two actions:

1. Converts the input string to the time zone of the **AT TIME ZONE** argument.
2. Returns the time for the current session's time zone.

If the input string includes a time zone, Vertica implicitly casts it to a **TIMESTAMPTZ** and converts it accordingly (see **TIMESTAMPTZ** below).

For example, the following statement specifies a **TIMESTAMP** with no time zone. Vertica executes the statement as follows:

1. Converts the input string to PDT (Pacific Daylight Time).
2. Returns that time in the local time zone, which is three hours later:

```
=> SHOW TIMEZONE;
name | setting
-----+-----
timezone | America/New_York
(1 row)

SELECT TIMESTAMP '2017-3-14 5:30' AT TIME ZONE 'PDT';
 timezone

2017-03-14 08:30:00-04
(1 row)
```

## TIMESTAMPTZ

Vertica converts the input string to the time zone of the **AT TIME ZONE** argument and returns that time.

For example, the following statement specifies a **TIMESTAMPTZ** data type. The input string omits any time zone expression, so Vertica assumes the input string to be in local time zone ( **America/New\_York** ) and returns the time of the **AT TIME ZONE** argument:

```
=> SHOW TIMEZONE;
name | setting
-----+-----
timezone | America/New_York
(1 row)

=> SELECT TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40' AT TIME ZONE 'America/Denver';
 timezone

2001-02-16 18:38:40
(1 row)
```

The input string in the next statement explicitly specifies a time zone, so Vertica coerces the **TIMESTAMP** to a **TIMESTAMPTZ** and returns the time of the **AT TIME ZONE** argument:

```
=> SELECT TIMESTAMP '2001-02-16 20:38:40 America/Mexico_City' AT TIME ZONE 'Asia/Tokyo';
 timezone

2001-02-17 11:38:40
(1 row)
```

### Specifying time zones

You can specify time zones in two ways:

- A string literal such as **America/Chicago** or **PST**
- An interval that specifies a UTC offset—for example, **INTERVAL '-08:00'**

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is **-04**, both queries return the same results:

```
=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
 Denver Time

2017-03-16 07:56:13
(1 row)

=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
 Denver Time

2017-03-16 07:56:13
(1 row)
```

If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to **-07**—otherwise, Vertica returns a different (and erroneous) result:

```
=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
 Denver Time

2017-0-16 07:56:13
(1 row)

=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
 Denver Time

2017-01-16 08:56:13
(1 row)
```

You can show and set the session's time zone with [SHOW TIMEZONE](#) and [SET TIME ZONE](#), respectively:

```
=> SHOW TIMEZONE;
 name | setting
-----+-----
timezone | America/New_York
(1 row)

=> SELECT CURRENT_TIMESTAMP(0) "Eastern Daylight Time";
 Eastern Daylight Time

2017-03-20 12:18:24-04
(1 row)

=> SET TIMEZONE 'America/Los_Angeles';
SET

=> SELECT CURRENT_TIMESTAMP(0) "Pacific Daylight Time";
 Pacific Daylight Time

2017-03-20 09:18:24-07
(1 row)
```

#### Time zone literals

To view the default list of valid literals, see the files in the following directory:

```
opt/vertica/share/timezonesets
```

For example:

```
$ cat Antarctica.txt
```

```
...
src/timezone/tznames/Antarctica.txt

AWST 28800 # Australian Western Standard Time
(Antarctica/Casey)
(Australia/Perth)
...
NZST 43200 # New Zealand Standard Time
(Antarctica/McMurdo)
(Pacific/Auckland)
ROTT -10800 # Rothera Time
(Antarctica/Rothera)
SYOT 10800 # Syowa Time
(Antarctica/Syowa)
VOST 21600 # Vostok time
(Antarctica/Vostok)
```

See also

- [TIME AT TIME ZONE](#)
- [TZ environment variable](#)
- [Using time zones with Vertica](#)
- [Sources for Time Zone and Daylight Saving Time Data](#)

## Long data types

Store data up to 32000000 octets. Vertica supports two long data types:

- **LONG VARBINARY** : Variable-length raw-byte data, such as spatial data. **LONG VARBINARY** values are not extended to the full width of the column.
- **LONG VARCHAR** : Variable-length strings, such as log files and unstructured data. **LONG VARCHAR** values are not extended to the full width of the column.

Use **LONG** data types only when you need to store data greater than the maximum size of **VARBINARY** and **VARCHAR** data types (65 KB). Long data can include unstructured data, online comments or posts, or small log files.

Flex tables have a default **LONG VARBINARY \_\_raw\_\_** column, with a **NOT NULL** constraint. For more information, see [Flex tables](#).

## Syntax

```
LONG VARBINARY [(max-length)]
LONG VARCHAR [(octet-length)]
```

## Parameters

### **max-length**

Length of the byte string or column width, declared in bytes (octets), up to 32000000.

**Default:** 1 MB

### **octet-length**

Length of the string or column width, declared in bytes (octets), up to 32000000.

**Default:** 1 MB

## Optimized performance

For optimal performance of **LONG** data types, Vertica recommends that you:

- Use the **LONG** data types as *storage only* containers; Vertica supports operations on the content of **LONG** data types, but does not support all the operations that **VARCHAR** and **VARBINARY** take.
- Use **VARBINARY** and **VARCHAR** data types, instead of their **LONG** counterparts, whenever possible. **VARBINARY** and **VARCHAR** data types are more flexible and have a wider range of operations.
- Do not sort, segment, or partition projections on **LONG** data type columns.

- Do not add constraints, such as a primary key, to any **LONG VARBINARY** or **LONG VARCHAR** columns.
- Do not join or aggregate any **LONG** data type columns.

## Examples

The following example creates a table `user_comments` with a **LONG VARCHAR** column and inserts data into it:

```
=> CREATE TABLE user_comments
 (id INTEGER,
 username VARCHAR(200),
 time_posted TIMESTAMP,
 comment_text LONG VARCHAR(200000));
=> INSERT INTO user_comments VALUES
 (1,
 'User1',
 TIMESTAMP '2013-06-25 12:47:32.62',
 'The weather tomorrow will be cold and rainy and then
 on the day after, the sun will come and the temperature
 will rise dramatically.');
```

## Numeric data types

Numeric data types are numbers stored in database columns. These data types are typically grouped by:

- **Exact** numeric types, values where the precision and scale need to be preserved. The exact numeric types are **INTEGER** , **BIGINT** , **DECIMAL** , **NUMERIC** , **NUMBER** , and **MONEY** .
- **Approximate** numeric types, values where the precision needs to be preserved and the scale can be floating. The approximate numeric types are **DOUBLE PRECISION** , **FLOAT** , and **REAL** .

Implicit casts from **INTEGER** , **FLOAT** , and **NUMERIC** to **VARCHAR** are not supported. If you need that functionality, write an explicit cast using one of the following forms:

```
CAST(numeric-expression AS data-type)
numeric-expression::data-type
```

For example, you can cast a float to an integer as follows:

```
=> SELECT(FLOAT '123.5')::INT;
?column?

 124
(1 row)
```

String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- Scientific notation :

```
=> SELECT FLOAT '1e10';
?column?

10000000000
(1 row)
```

- **BINARY** scaling :

```
=> SELECT NUMERIC '1p10';
?column?

 1024
(1 row)
```

- hexadecimal:

```
=> SELECT NUMERIC '0x0abc';
?column?

 2748
(1 row)
```

In this section

- [DOUBLE PRECISION \(FLOAT\)](#)
- [INTEGER](#)
- [NUMERIC](#)
- [Numeric data type overflow](#)
- [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#)

## DOUBLE PRECISION (FLOAT)

Vertica supports the numeric data type **DOUBLE PRECISION**, which is the IEEE-754 8-byte floating point type, along with most of the usual floating point operations.

### Syntax

```
[DOUBLE PRECISION | FLOAT | FLOAT(n) | FLOAT8 | REAL]
```

### Parameters

#### Note

On a machine whose floating-point arithmetic does not follow IEEE-754, these values probably do not work as expected.

Double precision is an inexact, variable-precision numeric type. In other words, some values cannot be represented exactly and are stored as approximations. Thus, input and output operations involving double precision might show slight discrepancies.

- All of the **DOUBLE PRECISION** data types are synonyms for 64-bit IEEE FLOAT.
- The *n* in **FLOAT(n)** must be between 1 and 53, inclusive, but a 53-bit fraction is always used. See the IEEE-754 standard for details.
- For exact numeric storage and calculations (money for example), use **NUMERIC**.
- Floating point calculations depend on the behavior of the underlying processor, operating system, and compiler.
- Comparing two floating-point values for equality might not work as expected.
- While Vertica treats decimal values as **FLOAT** internally, if a column is defined as **FLOAT** then you cannot read decimal values from ORC and Parquet files. In those formats, **FLOAT** and **DECIMAL** are different types.

### Values

**COPY** accepts floating-point data in the following format:

- Optional leading white space
- An optional plus ("+") or minus sign ("-")
- A decimal number, a hexadecimal number, an infinity, a NAN, or a null value

### Decimal Number

A decimal number consists of a non-empty sequence of decimal digits possibly containing a radix character (decimal point "."), optionally followed by a decimal exponent. A decimal exponent consists of an "E" or "e", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 10.

### Hexadecimal Number

A hexadecimal number consists of a "0x" or "0X" followed by a non-empty sequence of hexadecimal digits possibly containing a radix character, optionally followed by a binary exponent. A binary exponent consists of a "P" or "p", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 2. At least one of radix character and binary exponent must be present.

### Infinity

An infinity is either **INF** or **INFINITY**, disregarding case.

### NaN (Not A Number)

A NaN is **NAN** (disregarding case) optionally followed by a sequence of characters enclosed in parentheses. The character string specifies the value of NaN in an implementation-dependent manner. (The Vertica internal representation of NaN is 0xffff800000000000LL on x86 machines.)

When writing infinity or NaN values as constants in a SQL statement, enclose them in single quotes. For example:

```
=> UPDATE table SET x = 'Infinity'
```

#### Note

Vertica follows the IEEE definition of NaNs (IEEE 754). The SQL standards do not specify how floating point works in detail.

IEEE defines NaNs as a set of floating point values where each one is not equal to anything, even to itself. A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.

However, for the purpose of sorting data, NaN values must be placed somewhere in the result. The value generated 'NaN' appears in the context of a floating point number matches the NaN value generated by the hardware. For example, Intel hardware generates (0xffff800000000000LL), which is technically a Negative, Quiet, Non-signaling NaN.

Vertica uses a different NaN value to represent floating point NULL (0x7ffffffffffffeLL). This is a Positive, Quiet, Non-signaling NaN and is reserved by Vertica

A NaN example follows.

```
=> SELECT CBRT('NaN'); -- cube root
CBRT

NaN
(1 row)
=> SELECT 'NaN' > 1.0;
?column?

f
(1 row)
```

#### Null Value

The load file format of a null value is user defined, as described in the [COPY](#) command. The Vertica internal representation of a null value is 0x7ffffffffffffeLL. The interactive format is controlled by the [vsq!](#) printing option null. For example:

```
\pset null '(null)'
```

The default option is not to print anything.

#### Rules

- -0 == +0
- 1/0 = Infinity
- 0/0 == Nan
- NaN != anything (even NaN)

To search for NaN column values, use the following predicate:

```
... WHERE column != column
```

This is necessary because **WHERE** *column* = 'NaN' cannot be true by definition.

Sort order (ascending)

- NaN
- -Inf
- numbers
- +Inf
- NULL

#### Notes

- **NULL** appears last (largest) in ascending order.

- All overflows in floats generate +/-infinity or NaN, per the IEEE floating point standard.

## INTEGER

A signed 8-byte (64-bit) data type.

### Syntax

```
[INTEGER | INT | BIGINT | INT8 | SMALLINT | TINYINT]
```

### Parameters

**INT** , **INTEGER** , **INT8** , **SMALLINT** , **TINYINT** , and **BIGINT** are all synonyms for the same signed 64-bit integer data type. Automatic compression techniques are used to conserve disk space in cases where the full 64 bits are not required.

### Notes

- The range of values is  $-2^{63}+1$  to  $2^{63}-1$ .
- $2^{63} = 9,223,372,036,854,775,808$  (19 digits).
- The value  $-2^{63}$  is reserved to represent NULL.
- **NULL** appears first (smallest) in ascending order.
- Vertica does not have an explicit 4-byte (32-bit integer) or smaller types. Vertica's encoding and compression automatically eliminate the storage overhead of values that fit in less than 64 bits.

### Restrictions

- The JDBC type INTEGER is 4 bytes and is not supported by Vertica. Use **BIGINT** instead.
- Vertica does not support the SQL/JDBC types **NUMERIC** , **SMALLINT** , or **TINYINT** .
- Vertica does not check for overflow (positive or negative) except in the aggregate function **SUM()** . If you encounter overflow when using **SUM** , use **SUM\_FLOAT()** , which converts to floating point.

[Data Type Coercion Chart](#)

## NUMERIC

Numeric data types store fixed-point numeric data. For example, a value of \$123.45 can be stored in a **NUMERIC(5,2)** field. Note that the first number, the precision, specifies the *total* number of digits.

### Syntax

```
numeric-type [(precision[, scale])]
```

### Parameters

#### **numeric-type**

One of the following:

- NUMERIC
- DECIMAL
- NUMBER
- MONEY

#### **precision**

An unsigned integer that specifies the total number of significant digits that the data type stores, where *precision* is  $\leq 1024$ . If omitted, the [default precision](#) depends on numeric type that you specify. If you assign a value that exceeds *precision* , Vertica returns an error.

If a data type's precision is  $\leq 18$ , performance is equivalent to an INTEGER data type, regardless of scale. When possible, Vertica recommends using a precision  $\leq 18$ .

#### **scale**

An unsigned integer that specifies the maximum number of digits to the right of the decimal point to store. *scale* must be  $\leq$  *precision* . If omitted, the [default scale](#) depends on numeric type that you specify. If you assign a value with more decimal digits than *scale* , the scale is rounded to *scale* digits.

When using ALTER to modify the data type of a numeric column, *scale* cannot be changed.

### Default precision and scale

**NUMERIC** , **DECIMAL** , **NUMBER** , and **MONEY** differ in their default precision and scale values:

Type	Precision	Scale
NUMERIC	37	15
DECIMAL	37	15
NUMBER	38	0
MONEY	18	4

Supported encoding

Vertica supports the following encoding for [numeric data types](#) :

- Precision ≤ 18: [AUTO](#) , [BLOCK\\_DICT](#) , [BLOCKDICT\\_COMP](#) , [COMMONDELTA\\_COMP](#) , [DELTAVAL](#) , [GCDDELTA](#) , and [RLE](#)
- Precision > 18: [AUTO](#) , [BLOCK\\_DICT](#) , [BLOCKDICT\\_COMP](#) , [RLE](#)

For details, see [Encoding types](#) .

Numeric versus integer and floating data types

Numeric data types are *exact* data types that store values of a specified precision and scale, expressed with a number of digits before and after a decimal point. This contrasts with the Vertica integer and floating data types:

- [DOUBLE PRECISION \(FLOAT\)](#) supports ~15 digits, variable exponent, and represents numeric values approximately. It can be less precise than NUMERIC data types.
- [INTEGER](#) supports ~18 digits, whole numbers only.

The NUMERIC data type is preferred for non-integer constants, because it is always exact. For example:

```
=> SELECT 1.1 + 2.2 = 3.3;
?column?

t
(1 row)

=> SELECT 1.1::float + 2.2::float = 3.3::float;
?column?

f
(1 row)
```

Numeric operations

Supported numeric operations include the following:

- [Basic math](#) : + , - , \* , /
- [Aggregation](#) : [SUM](#) , [MIN](#) , [MAX](#) , [COUNT](#)
- [Comparison](#) : < , <= , = , <=> , <> , > , >=

NUMERIC divide operates directly on numeric values, without converting to floating point. The result has at least 18 decimal places and is rounded.

NUMERIC mod (including %) operates directly on numeric values, without converting to floating point. The result has the same scale as the numerator and never needs rounding.

Some complex operations used with numeric data types result in an implicit cast to FLOAT. When using SQRT, STDDEV, transcendental functions such as LOG, and TO\_CHAR/TO\_NUMBER formatting, the result is always FLOAT.

Examples

The following series of commands creates a table that contains a numeric data type and then performs some mathematical operations on the data:

```
=> CREATE TABLE num1 (id INTEGER, amount NUMERIC(8,2));
```

Insert some values into the table:

```
=> INSERT INTO num1 VALUES (1, 123456.78);
```

Query the table:

```
=> SELECT * FROM num1;
 id | amount
-----+-----
 1 | 123456.78
(1 row)
```

The following example returns the NUMERIC column, amount, from table num1:

```
=> SELECT amount FROM num1;
 amount

123456.78
(1 row)
```

The following syntax adds one (1) to the amount:

```
=> SELECT amount+1 AS 'amount' FROM num1;
 amount

123457.78
(1 row)
```

The following syntax multiplies the amount column by 2:

```
=> SELECT amount*2 AS 'amount' FROM num1;
 amount

246913.56
(1 row)
```

The following syntax returns a negative number for the amount column:

```
=> SELECT -amount FROM num1;
?column?

-123456.78
(1 row)
```

The following syntax returns the absolute value of the amount argument:

```
=> SELECT ABS(amount) FROM num1;
 ABS

123456.78
(1 row)
```

The following syntax casts the NUMERIC amount as a FLOAT data type:

```
=> SELECT amount::float FROM num1;
 amount

123456.78
(1 row)
```

[Mathematical functions](#)

Numeric data type overflow

Vertica does not check for overflow (positive or negative) except in the aggregate function [SUM\(\)](#) . If you encounter overflow when using [SUM](#) , use [SUM\\_FLOAT\(\)](#) which converts to floating point.

For a detailed discussion of how Vertica handles overflow when you use the functions [SUM](#), [SUM\\_FLOAT](#), and [AVG](#) with numeric data types, see [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#) . The discussion includes directives for turning off silent numeric overflow and setting precision for numeric data types. Dividing by zero returns an error:

```

=> SELECT 0/0;
ERROR 3117: Division by zero

=> SELECT 0.0/0;
ERROR 3117: Division by zero

=> SELECT 0 // 0;
ERROR 3117: Division by zero

=> SELECT 200.0/0;
ERROR 3117: Division by zero

=> SELECT 116.43 // 0;
ERROR 3117: Division by zero

```

Dividing zero as a FLOAT by zero returns NaN:

```

=> SELECT 0.0::float/0;
?column?

NaN
=> SELECT 0.0::float//0;
?column?

NaN

```

Dividing a non-zero FLOAT by zero returns Infinity:

```

=> SELECT 2.0::float/0;
?column?

Infinity
=> SELECT 200.0::float//0;
?column?

Infinity

```

Add, subtract, and multiply operations ignore overflow. Sum and average operations use 128-bit arithmetic internally. [SUM\(\)](#) reports an error if the final result overflows, suggesting the use of [SUM\\_FLOAT\(INT\)](#), which converts the 128-bit sum to a [FLOAT](#). For example:

```

=> CREATE TEMP TABLE t (i INT);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> INSERT INTO t VALUES (1<<62);
=> SELECT SUM(i) FROM t;
ERROR: sum() overflowed
HINT: try sum_float() instead
=> SELECT SUM_FLOAT(i) FROM t;
SUM_FLOAT

2.30584300921369e+19

```

#### Numeric data type overflow with SUM, SUM\_FLOAT, and AVG

When you use the SUM, SUM\_FLOAT, and AVG functions (aggregate and analytic) to query a [numeric](#) column, overflow can occur. How Vertica responds to that overflow depends on the settings of two configuration parameters:

- [AllowNumericOverflow](#) (Boolean, default 1) allows numeric overflow. Vertica does not implicitly extend precision of numeric data types.
- [NumericSumExtraPrecisionDigits](#) (integer, default 6) determines whether to return an overflow error if a result exceeds the specified precision. This parameter is ignored if AllowNumericOverflow is set to 1 (true).

Vertica also allows numeric overflow when you use SUM or SUM\_FLOAT to query pre-aggregated data. See [Impact on Pre-Aggregated Data Projections](#) below.

### Default overflow handling

With numeric columns, Vertica internally works with multiples of 18 digits. If specified precision is less than 18—for example, `x(12,0)`—Vertica allows overflow up to and including the first multiple of 18. In some situations, if you sum a column, you can exceed the number of digits Vertica internally reserves for the result. In this case, Vertica allows silent overflow.

### Turning off silent numeric overflow

You can turn off silent numeric overflow by setting `AllowNumericOverflow` to 0. In this case, Vertica checks the value of configuration parameter `NumericSumExtraPrecisionDigits`. By default, this parameter is set to 6, which means that Vertica internally adds extra digit places beyond a column's DDL-specified precision. Adding extra precision digits enables Vertica to consistently return results that overflow the column's precision. However, crossing into the second multiple of 18 internally can adversely impact performance.

For example, if `AllowNumericOverflow` is set to 0 :

- Column `x` is defined as `x(12,0)` and `NumericSumExtraPrecisionDigits` is set to 6: Vertica internally stays within the first multiple of 18 digits and no additional performance impact occurs ( `a` ).
- Column `x` is defined as `x(2,0)` and `NumericSumExtraPrecisionDigits` is set to 20: Vertica internally crosses a threshold into the second multiple of 18. In this case, performance is significantly affected ( `2a` ). Performance beyond the second multiple of 18 continues to be `2a` .

### Tip

Vertica recommends that you turn off silent numeric overflow and set the parameter `NumericSumExtraPrecisionDigits` if you expect query results to exceed the precision specified in the DDL of numeric columns. Be aware of the following considerations:

- If you turn off `AllowNumericOverflow` and exceed the number of extra precision digits set by `NumericSumExtraPrecisionDigits`, Vertica returns an error.
- Be careful to set `NumericSumExtraPrecisionDigits` only as high as necessary to return the SUM of numeric columns.

### Impact on pre-aggregated data projections

Vertica supports silent numeric overflow for queries that use SUM or SUM\_FLOAT on projections with [pre-aggregated data](#) such as [live aggregate](#) or [Top-K](#) projections. To turn off silent numeric overflow for these queries:

1. Set `AllowNumericOverflow` to 0.
2. Set `NumericSumExtraPrecisionDigits` to the desired number of implicit digits. Alternatively, use the default setting of 6.
3. Drop and re-create the affected projections.

If you turn off silent numeric overflow, be aware that overflow can sometimes cause rollback or errors:

- Overflow occurs during load operations, such as COPY, MERGE, or INSERT:  
Vertica aggregates data before loading the projection with data. If overflow occurs while data is aggregated, Vertica rolls back the load operation.
- Overflow occurs after load, while Vertica sums existing data.  
Vertica computes the sum of existing data separately from the computation that it does during data load. If the projection selects a column with SUM or SUM\_FLOAT and overflow occurs, Vertica produces an error message. This response resembles the way Vertica produces an error for a query that uses SUM or SUM\_FLOAT.
- Overflow occurs during [mergeout](#).  
Vertica logs a message during mergeout if overflow occurs while Vertica computes a final sum during the mergeout operation. If an error occurs, Vertica marks the projection as out of date and disqualifies it from further mergeout operations.

## Spatial data types

Vertica supports two spatial data types. These data types store two- and three-dimensional spatial objects in a table column:

- **GEOMETRY** : Spatial object with coordinates expressed as ( *x* , *y* ) pairs, defined in the Cartesian plane. All calculations use Cartesian coordinates.
- **GEOGRAPHY** : Spatial object defined as on the surface of a perfect sphere, or a spatial object in the WGS84 coordinate system. Coordinates are expressed in longitude/latitude angular values, measured in degrees. All calculations are in meters. For perfect sphere calculations, the sphere has a radius of 6371 kilometers, which approximates the shape of the earth.

### Note

Some spatial programs use an ellipsoid to model the earth, resulting in slightly different data.

The maximum size of a **GEOMETRY** or **GEOGRAPHY** data type is 10,000,000 bytes (10 MB). You cannot use either data type as a table's primary key.

### Syntax

```
GEOMETRY [(length)]
GEOGRAPHY [(length)]
```

### Parameters

#### **length**

The maximum amount of spatial data that a **GEOMETRY** or **GEOGRAPHY** column can store, up to 10 MB.

**Default:** 1 MB

## UUID data type

Stores universally unique identifiers (UUIDs). UUIDs are 16-byte (128-bit) numbers used to uniquely identify records. To generate UUIDs, Vertica provides the function [UUID\\_GENERATE](#), which returns UUIDs based on high-quality randomness from `/dev/urandom`.

### Syntax

```
UUID
```

### UUID input and output formats

UUIDs support input of case-insensitive string literal formats, as specified by [RFC 4122](#). In general, a UUID is written as a sequence of hexadecimal digits, in several groups optionally separated by hyphens, for a total of 32 digits representing 128 bits.

The following input formats are valid:

```
6bbf0744-74b4-46b9-bb05-53905d4538e7
{6bbf0744-74b4-46b9-bb05-53905d4538e7}
6BBF074474B446B9BB0553905D4538E7
6BBf-0744-74B4-46B9-BB05-5390-5D45-38E7
```

On output, Vertica always uses the following format:

```
xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx
```

For example, the following table defines column `cust_id` as a UUID:

```
=> CREATE TABLE public.Customers
(
 cust_id uuid,
 lname varchar(36),
 fname varchar(24)
);
```

The following input for `cust_id` uses several valid formats:

```
=> COPY Customers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {cede66b7-3d29-4da6-b700-871fc0ac57be}|Kearney|Thomas
>> 34462732ed5649838f3be735b0c32d50|Pham|Duc
>> 9fb0-1de0-1d63-4d09-9415-90e0-b4e9-3b9a|Steinberg|Jeremy
>> \.
```

On querying this table, Vertica formats all `cust_id` data in the same way:

```
=> SELECT cust_id, fname, lname FROM Customers;
 cust_id | fname | lname
-----+-----+-----
9fb01de0-1d63-4d09-9415-90e0b4e93b9a | Jeremy | Steinberg
34462732-ed56-4983-8f3b-e735b0c32d50 | Duc | Pham
cede66b7-3d29-4da6-b700-871fc0ac57be | Thomas | Kearney
(3 rows)
```

### Generating UUIDs

You can use the Vertica function [UUID\\_GENERATE](#) to automatically generate UUIDs that uniquely identify table records. For example:

```
=> INSERT INTO Customers SELECT UUID_GENERATE(),'Rostova','Natasha';
OUTPUT

 1
(1 row)

=> COMMIT;
COMMIT
=> SELECT cust_id, fname, lname FROM Customers;
 cust_id | fname | lname
-----+-----+-----
9fb01de0-1d63-4d09-9415-90e0b4e93b9a | Jeremy | Steinberg
34462732-ed56-4983-8f3b-e735b0c32d50 | Duc | Pham
cede66b7-3d29-4da6-b700-871fc0ac57be | Thomas | Kearney
9aad6757-fe1b-473a-a109-b89b7b358c69 | Natasha | Rostova
(4 rows)
```

### NULL input and output

The following string is reserved as NULL for UUID columns:

```
00000000-0000-0000-0000-000000000000
```

Vertica always renders NULL as blank.

The following `COPY` statements insert NULL values into the UUID column, explicitly and implicitly:

```
=> COPY Customers FROM STDIN NULL AS 'null';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> null|Doe|Jane
>> 00000000-0000-0000-0000-000000000000|Man|Nowhere
>> \.
=> COPY Customers FROM STDIN;
>> |Doe|John
>> \.
```

In all cases, Vertica renders NULL as blank:

```
=> SELECT cust_id, fname, lname FROM Customers WHERE cust_id IS NULL;
```

```
cust_id | fname | lname
```

```
-----+-----+-----
| Nowhere | Man
| Jane | Doe
| John | Doe
```

```
(3 rows)
```

## Usage restrictions

UUID data types only support relational operators and functions that are also supported by CHAR and VARCHAR data types—for example, [MIN](#), [MAX](#), and [COUNT](#). UUID data types do not support mathematical operators or functions, such as [SUM](#) and [AVG](#).

## Data type coercion

Vertica supports two types of data type casting:

- *Implicit casting*: The expression automatically converts the data from one type to another.
- *Explicit casting*: A SQL statement specifies the target data type for the conversion.

### Implicit casting

The ANSI SQL-92 standard supports implicit casting among similar data types:

- Number types
- CHAR, VARCHAR, LONG VARCHAR
- BINARY, VARBINARY, LONG VARBINARY

Vertica supports two types of nonstandard implicit casts of scalar types:

- From CHAR to FLOAT, to match the one from VARCHAR to FLOAT. The following example converts the CHAR '3' to a FLOAT so it can add the number 4.33 to the FLOAT result of the second expression:

```
=> SELECT '3'::CHAR + 4.33::FLOAT;
```

```
?column?
```

```

7.33
```

```
(1 row)
```

- Between DATE and TIMESTAMP. The following example DATE to a TIMESTAMP and calculates the time 6 hours, 6 minutes, and 6 seconds back from 12:00 AM:

```
=> SELECT DATE('now') - INTERVAL '6:6:6';
```

```
?column?
```

```

2013-07-30 17:53:54
```

```
(1 row)
```

When there is no ambiguity about the data type of an expression value, it is implicitly coerced to match the expected data type. In the following statement, the quoted string constant '2' is implicitly coerced into an INTEGER value so that it can be the operand of an arithmetic operator (addition):

```
=> SELECT 2 + '2';
```

```
?column?
```

```

4
```

```
(1 row)
```

A concatenate operation explicitly takes arguments of any data type. In the following example, the concatenate operation implicitly coerces the arithmetic expression `2 + 2` and the INTEGER constant `2` to VARCHAR values so that they can be concatenated.

```
=> SELECT 2 + 2 || 2;
```

```
?column?
```

```

42
```

```
(1 row)
```

Another example is to first get today's date:

```
=> SELECT DATE 'now';
?column?
```

```

2013-07-31
(1 row)
```

The following command converts DATE to a TIMESTAMP and adds a day and a half to the results by using INTERVAL:

```
=> SELECT DATE 'now' + INTERVAL '1 12:00:00';
?column?
```

```

2013-07-31 12:00:00
(1 row)
```

Most implicit casts stay within their relational family and go in one direction, from less detailed to more detailed. For example:

- DATE to TIMESTAMP/TZ
- INTEGER to NUMERIC to FLOAT
- CHAR to FLOAT
- CHAR to VARCHAR
- CHAR and/or VARCHAR to FLOAT
- CHAR to LONG VARCHAR
- VARCHAR to LONG VARCHAR
- BINARY to VARBINARY
- BINARY to LONG VARBINARY
- VARBINARY to LONG VARBINARY

More specifically, data type coercion works in this manner in Vertica:

Conversion	Notes
INT8 > FLOAT8	Implicit, can lose significance
FLOAT8 > INT8	Explicit, rounds
VARCHAR <-> CHAR	Implicit, adjusts trailing spaces
VARBINARY <-> BINARY	Implicit, adjusts trailing NULs
VARCHAR > LONG VARCHAR	Implicit, adjusts trailing spaces
VARBINARY > LONG VARBINARY	Implicit, adjusts trailing NULs

No other types cast to or from LONGVARBINARY, VARBINARY, or BINARY. In the following list, <any> means one these types: INT8, FLOAT8, DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, INTERVAL:

- <any> -> VARCHAR—implicit
- VARCHAR -> <any>—explicit, except that VARCHAR->FLOAT is implicit
- <any> <-> CHAR—explicit
- DATE -> TIMESTAMP/TZ—implicit
- TIMESTAMP/TZ -> DATE—explicit, loses time-of-day
- TIME -> TIMETZ—implicit, adds local timezone
- TIMETZ -> TIME—explicit, loses timezone
- TIME -> INTERVAL—implicit, day to second with days=0
- INTERVAL -> TIME—explicit, truncates non-time parts
- TIMESTAMP <-> TIMESTAMPTZ—implicit, adjusts to local timezone
- TIMESTAMP/TZ -> TIME—explicit, truncates non-time parts
- TIMESTAMPTZ -> TIMETZ—explicit
- VARBINARY -> LONG VARBINARY—implicit
- LONG VARBINARY -> VARBINARY—explicit
- VARCHAR -> LONG VARCHAR—implicit
- LONG VARCHAR -> VARCHAR—explicit

## Important

Implicit casts from INTEGER, FLOAT, and NUMERIC to VARCHAR are not supported. If you need that functionality, write an explicit cast:

```
CAST(x AS data-type-name)
```

or

```
x::data-type-name
```

The following example casts a FLOAT to an INTEGER:

```
=> SELECT(FLOAT '123.5')::INT;
?column?

 124
(1 row)
```

String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- Scientific notation :

```
=> SELECT FLOAT '1e10';
?column?

10000000000
(1 row)
```

- **BINARY** scaling :

```
=> SELECT NUMERIC '1p10';
?column?

 1024
(1 row)
```

- hexadecimal:

```
=> SELECT NUMERIC '0x0abc';
?column?

 2748
(1 row)
```

## Complex types

Collections ( [arrays](#) and [sets](#) ) can be cast implicitly and explicitly. Casting a collection casts each element of the collection. You can, for example, cast an ARRAY[VARCHAR] to an ARRAY[INT] or a SET[DATE] to SET[TIMESTAMPZ]. You can cast between arrays and sets.

When casting to a bounded native array, inputs that are too long are truncated. When casting to a non-native array (an array containing complex data types including other arrays), if the new bounds are too small for the data the cast fails

[Rows](#) (structs) can be cast implicitly and explicitly. Casting a ROW casts each field value. You can specify new field names in the cast or specify only the field types to use the existing field names.

Casting can increase the storage needed for a column. For example, if you cast an array of INT to an array of VARCHAR(50), each element takes more space and thus the array takes more space. If the difference is extreme or the array has many elements, this could mean that the array no longer fits within the space allotted for the column. In this case the operation reports an error and fails.

## Examples

The following example casts three strings as NUMERICs:

```
=> SELECT NUMERIC '12.3e3', '12.3p10'::NUMERIC, CAST('0x12.3p-10e3' AS NUMERIC);
?column? | ?column? | ?column?
-----+-----+-----
 12300 | 12595.2 | 17.76123046875000
(1 row)
```

This example casts a VARBINARY string into a LONG VARBINARY data type:

```
=> SELECT B'101111000'::LONG VARBINARY;
?column?

\001x
(1 row)
```

The following example concatenates a CHAR with a LONG VARCHAR, resulting in a LONG VARCHAR:

```
=> \set s ""cat longfile.txt""
=> SELECT length ('a' || :s ::LONG VARCHAR);
length

65002
(1 row)
```

The following example casts a combination of NUMERIC and INTEGER data into a NUMERIC result:

```
=> SELECT (18. + 3./16)/1024*1000;
?column?

17.76123046875000000000000000000000000000
(1 row)
```

**Note**  
In SQL expressions, pure numbers between  $(-2^{63}-1)$  and  $(2^{63}-1)$  are INTEGERS. Numbers with decimal points are NUMERIC.

Data type coercion chart

Conversion types

The following table defines all possible type conversions that Vertica supports. The data types in the first column of the table are the inputs to convert, and the remaining columns indicate the result for the different conversion types.

Source Data Type	Implicit	Explicit	Assignment	Assignment without numeric meaning	Conversion without explicit casting
BOOLEAN			INTEGER, LONG VARCHAR, VARCHAR, CHAR		
INTEGER	BOOLEAN, NUMERIC, FLOAT		INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH	LONG VARCHAR, VARCHAR, CHAR	
NUMERIC	FLOAT		INTEGER	LONG VARCHAR, VARCHAR, CHAR	NUMERIC

FLOAT			INTEGER, NUMERIC	LONG VARCHAR, VARCHAR, CHAR	
LONG VARCHAR	FLOAT, CHAR	BOOLEAN, INTEGER, NUMERIC, VARCHAR, TIMESTAMP, TIMESTAMPTZ, DATE, TIME, TIMETZ, INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH, LONG VARBINARY			LONG VARCHAR
VARCHAR	CHAR, FLOAT, LONG VARCHAR	BOOLEAN, INTEGER, NUMERIC, TIMESTAMP, TIMESTAMPTZ, DATE, TIME, TIMETZ, UUID, BINARY, VARBINARY, INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH			VARCHAR
CHAR	FLOAT, LONG VARCHAR, VARCHAR	BOOLEAN, INTEGER, NUMERIC, TIMESTAMP, TIMESTAMPTZ, DATE, TIME, TIMETZ, UUID (CHAR length $\geq$ 36), BINARY, VARBINARY, INTERVAL DAY/SECOND, INTERVAL YEAR/MONTH			CHAR
TIMESTAMP	TIMESTAMPTZ		LONG CHAR, VARCHAR, CHAR, DATE, TIME		TIMESTAMP
TIMESTAMPTZ	TIMESTAMP		LONG CHAR, VARCHAR, CHAR, DATE, TIME, TIMETZ		TIMESTAMPTZ
DATE	TIMESTAMP		LONG CHAR, VARCHAR, CHAR, TIMESTAMPTZ		
TIME	TIMETZ	TIMESTAMP, TIMESTAMPTZ, INTERVAL DAY/SECOND	LONG CHAR, VARCHAR, CHAR		TIME
TIMETZ		TIMESTAMP, TIMESTAMPTZ	LONG CHAR, VARCHAR, CHAR, TIME		TIMETZ
INTERVAL DAY/SECOND		TIME	INTEGER, LONG CHAR, VARCHAR, CHAR		INTERVAL DAY/SECOND
INTERVAL YEAR/MONTH			INTEGER, LONG CHAR, VARCHAR, CHAR		INTERVAL YEAR/MONTH
LONG VARBINARY		VARBINARY			LONG VARBINARY
VARBINARY	LONG VARBINARY, BINARY				VARBINARY
BINARY	VARBINARY				BINARY

UUID		CHAR(36), VARCHAR			UUID
------	--	-------------------	--	--	------

### Implicit and explicit conversion

Vertica supports data type conversion of values without explicit casting, such as `NUMERIC(10,6) -> NUMERIC(18,4)`. Implicit data type conversion occurs automatically when converting values of different, but compatible, types to the target column's data type. For example, when adding values, (`INTEGER + NUMERIC`), the result is implicitly cast to a `NUMERIC` type to accommodate the prominent type in the statement. Depending on the input data types, different precision and scale can occur.

An explicit type conversion must occur when the source data cannot be cast implicitly to the target column's data type.

### Assignment conversion

In data assignment conversion, coercion implicitly occurs when values are assigned to database columns in an `INSERT` or `UPDATE...SET` statement. For example, in a statement that includes `INSERT...VALUES('2.5')`, where the target column data type is `NUMERIC(18,5)`, a cast from `VARCHAR` to the column data type is inferred.

In an assignment without numeric meaning, the value is subject to `CHAR/VARCHAR/LONG VARCHAR` comparisons.

- [Data type coercion](#)
- [Data type coercion operators \(CAST\)](#)

### Complex types

Complex types such as structures (also known as rows), arrays, and maps are composed of primitive types and sometimes other complex types. Complex types can be used in the following ways:

- Arrays and rows (in any combination) can be used as column data types in both native and external tables.
- Sets of primitive element types can be used as column data types in native and external tables.
- Arrays and rows, but not combinations of them, can be created as literals, for example to use in query expressions.

The `MAP` type is a legacy type. To represent maps, use `ARRAY[ROW]`.

If a flex table has a real column that uses a complex type, the values from that column are not included in the `__raw__` column. For more information, see [Loading Data into Flex Table Real Columns](#).

In this section

- [ARRAY](#)
- [MAP](#)
- [ROW](#)
- [SET](#)

### ARRAY

Represents array data. There are two types of arrays in Vertica:

- Native array: a one-dimensional array of a primitive type. Native arrays are tracked in the `TYPES` system table and used in native tables.
- Non-native array: all other supported arrays, including arrays that contain other arrays (multi-dimensional arrays) or structs (`ROW`s). Non-native arrays have some usage restrictions. Non-native arrays are tracked in the `COMPLEX_TYPES` system table.

Both types of arrays operate in the same way, but they have different OIDs.

Arrays can be bounded, meaning they specify a maximum element count, or unbounded. Unbounded arrays have a maximum binary size, which can be set explicitly or defaulted. See [Limits on Element Count and Collection Size](#).

Selected parsers support using `COPY` to load arrays. See the documentation of individual parsers for more information.

Syntax

In [column definitions](#):

```
ARRAY[data_type, max_elements] |
ARRAY[data_type](max_size) |
ARRAY[data_type]
```

In [literals](#):

```
ARRAY[value[, ...]]
```

#### Restrictions

- Native arrays support only data of primitive types, for example, int, UUID, and so on.
- Array dimensionality is enforced. A column cannot contain arrays of varying dimensions. For example, a column that contains a three-dimensional array can only contain other three-dimensional arrays; it cannot simultaneously include a one-dimensional array. However, the arrays in a column can vary in size, where one array can contain four elements while another contains ten.
- Array bounds, if specified, are enforced for all operations that load or alter data. Unbounded arrays may have as many elements as will fit in the allotted binary size.
- An array has a maximum binary size. If this size is not set when the array is defined, a default value is used.
- Arrays do not support LONG types (like LONG VARBINARY or LONG VARCHAR) or user-defined types (like Geometry).

#### Syntax for column definition

Arrays used in column definitions can be either bounded or unbounded. Bounded arrays must specify a maximum number of elements. Unbounded arrays can specify a maximum binary size (in bytes) for the array, or the value of [DefaultArrayBinarySize](#) is used. You can specify a bound or a binary size but not both. For more information about these values, see [Limits on Element Count and Collection Size](#).

Type	Syntax	Semantics
Bounded array	<p><i>ARRAY[ data_type , max_elements ]</i></p> <p>Example:</p> <p><i>ARRAY[VARCHAR(50),100]</i></p>	<p>Can contain no more than <i>max_elements</i> elements. Attempting to add more is an error.</p> <p>Has a binary size of the size of the data type multiplied by the maximum number of elements (possibly rounded up).</p>
Unbounded array with maximum binary size	<p><i>ARRAY[ data_type ]( max_size )</i></p> <p>Example:</p> <p><i>ARRAY[VARCHAR(50)](32000)</i></p>	<p>Can contain as many elements as fit in <i>max_size</i> . Ignores the value of <a href="#">DefaultArrayBinarySize</a>.</p>
Unbounded array with default binary size	<p><i>ARRAY[ data_type ]</i></p> <p>Example:</p> <p><i>ARRAY[VARCHAR(50)]</i></p>	<p>Can contain as many elements as fit in the default binary size.</p> <p>Equivalent to:</p> <p><i>ARRAY[ data_type ](DefaultArrayBinarySize)</i></p>

The following example defines a table for customers using an unbounded array:

```
=> CREATE TABLE customers (id INT, name VARCHAR, email ARRAY[VARCHAR(50)]);
```

The following example uses a bounded array for customer email addresses and an unbounded array for order history:

```
=> CREATE TABLE customers (id INT, name VARCHAR, email ARRAY[VARCHAR(50),5], orders ARRAY[INT]);
```

The following example uses an array that has ROW elements:

```
=> CREATE TABLE orders(
 orderid INT,
 accountid INT,
 shipments ARRAY[
 ROW(
 shipid INT,
 address ROW(
 street VARCHAR,
 city VARCHAR,
 zip INT
),
 shipdate DATE
)
]
);
```

To declare a multi-dimensional array, use nesting. For example, ARRAY[ARRAY[int]] specifies a two-dimensional array.

Syntax for direct construction (literals)

Use the ARRAY keyword to construct an array value. The following example creates an array of integer values.

```
=> SELECT ARRAY[1,2,3];
array

[1,2,3]
(1 row)
```

You can nest an array inside another array, as in the following example.

```
=> SELECT ARRAY[ARRAY[1],ARRAY[2]];
array

[[1],[2]]
(1 row)
```

If an array of arrays contains no null elements and no function calls, you can abbreviate the syntax:

```
=> SELECT ARRAY[[1,2],[3,4]];
array

[[1,2],[3,4]]
(1 row)
```

---not valid:

```
=> SELECT ARRAY[[1,2],null,[3,4]];
```

ERROR 4856: Syntax error at or near "null" at character 20

```
LINE 1: SELECT ARRAY[[1,2],null,[3,4]];
 ^
```

Array literals can contain elements of all scalar types, ROW, and ARRAY. ROW elements must all have the same set of fields:

```
=> SELECT ARRAY[ROW(1,2),ROW(1,3)];
array

[{"f0":1,"f1":2},{f0":1,"f1":3}]
(1 row)
```

```
=> SELECT ARRAY[ROW(1,2),ROW(1,3,'abc')];
```

ERROR 3429: For 'ARRAY', types ROW(int,int) and ROW(int,int,unknown) are inconsistent

Because the elements are known at the time you directly construct an array, these arrays are implicitly bounded.

You can use ARRAY literals in comparisons, as in the following example:

```
=> SELECT id.name, id.num, GPA FROM students
 WHERE major = ARRAY[ROW('Science','Physics')];
name | num | GPA
-----+-----+-----
bob | 121 | 3.3
carol | 123 | 3.4
(2 rows)
```

#### Output format

Queries of array columns return JSON format, with the values shown in comma-separated lists in brackets. The following example shows a query that includes array columns.

```
=> SELECT cust_custkey,cust_custstaddress,cust_custcity,cust_custstate from cust;
cust_custkey | cust_custstaddress | cust_custcity | cust_custstate
-----+-----+-----+-----
 342176 | ["668 SW New Lane","518 Main Ave","7040 Campfire Dr"] | ["Winchester","New Hyde Park","Massapequa"] | ["VA","NY","NY"]
 342799 | ["2400 Hearst Avenue","3 Cypress Street"] | ["Berkeley","San Antonio"] | ["CA","TX"]
 342845 | ["336 Boylston Street","180 Clarkhill Rd"] | ["Boston","Amherst"] | ["MA","MA"]
 342321 | ["95 Fawn Drive"] | ["Allen Park"] | ["MI"]
 342989 | ["5 Thompson St"] | ["Massillon"] | ["OH"]
(5 rows)
```

Note that JSON format escapes some characters that would not be escaped in native VARCHARs. For example, if you insert `"c:\users\data"` into an array, the JSON output for that value is `"c:\\users\\data"`.

#### Element access

Arrays are 0-indexed. The first element's ordinal position is 0, second is 1, and so on.

You can access (dereference) elements from an array by index:

```
=> SELECT (ARRAY['a','b','c','d','e'])[1];
array

b
(1 row)
```

To specify a range, use the format `start: end`. The end of the range is non-inclusive.

```
=> SELECT(ARRAY['a','b','c','d','e','f','g'])[1:4];
array

["b","c","d"]
(1 row)
```

To dereference an element from a multi-dimensional array, put each index in brackets:

```
=> SELECT(ARRAY[ARRAY[1,2],ARRAY[3,4]])[0][0];
array

1
(1 row)
```

Out-of-bound index references return NULL.

#### Limits on element count and collection size

When declaring a collection type for a table column, you can limit either the number of elements or the total binary size of the collection. During query processing, Vertica always reserves the maximum memory needed for the column, based on either the element count or the binary size. If this size is much larger than your data actually requires, setting one of these limits can improve query performance by reducing the amount of memory that must be reserved for the column.

You can change the bounds of a collection, including changing between bounded and unbounded collections, by casting. See [Casting](#).

A bounded collection specifies a maximum element count. A value in a bounded collection column may contain fewer elements, but it may not contain more. Any attempt to insert more elements into a bounded collection than the declared maximum is an error. A bounded collection has a binary size that is the product of the data-type size and the maximum number of elements, possibly rounded up.

An unbounded collection specifies a binary size in bytes, explicitly or implicitly. It may contain as many elements as can fit in that binary size.

If a nested array specifies bounds for all dimensions, Vertica sets a single bound that is the product of the bounds. In the following example, the inner and outer arrays each have a bound of 10, but only a total element count of 100 is enforced.

```
ARRAY[ARRAY[INT,10],10]
```

If a nested array specifies a bound for only the outer collection, it is treated as the total bound. The previous example is equivalent to the following:

```
ARRAY[ARRAY[INT],100]
```

You must either specify bounds for all nested collections or specify a bound only for the outer one. For any other distribution of bounds, Vertica treats the collection as unbounded.

Instead of specifying a bound, you can specify a maximum binary size for an unbounded collection. The binary size acts as an absolute limit, regardless of how many elements the collection contains. Collections that do not specify a maximum binary size use the value of [DefaultArrayBinarySize](#). This size is set at the time the collection is defined and is not affected by later changes to the value of `DefaultArrayBinarySize`.

You cannot set a maximum binary size for a bounded collection, only an unbounded one.

You can change the bounds or the binary size of an array column using [ALTER TABLE](#) as in the following example:

```
=> ALTER TABLE cust ALTER COLUMN orders SET DATA TYPE ARRAY[INTEGER](100);
```

If the change reduces the size of the collection and would result in data loss, the change fails.

## Comparisons

All collections support equality ( = ), inequality ( <> ), and null-safe equality ( <=> ). 1D collections also support comparison operators ( < , <= , > , >= ) between collections of the same type (arrays or sets). Comparisons follow these rules:

- A null collection is ordered last.
- Non-null collections are compared element by element, using the ordering rules of the element's data type. The relative order of the first pair of non-equal elements determines the order of the two collections.
- If all elements in both collections are equal up to the length of the shorter collection, the shorter collection is ordered before the longer one.
- If all elements in both collections are equal and the collections are of equal length, the collections are equal.

## Null-handling

Null semantics for collections are consistent with normal columns in most regards. See [NULL sort order](#) for more information on null-handling.

The null-safe equality operator ( <=> ) behaves differently from equality ( = ) when the collection is null rather than empty. Comparing a collection to NULL strictly returns null:

```
=> SELECT ARRAY[1,3] = NULL;
```

```
?column?
```

```

```

```
(1 row)
```

```
=> SELECT ARRAY[1,3] <=> NULL;
```

```
?column?
```

```

```

```
f
```

```
(1 row)
```

In the following example, the grants column in the table is null for employee 99:

```
=> SELECT grants = NULL FROM employees WHERE id=99;
```

```
?column?
```

```

```

```
(1 row)
```

```
=> SELECT grants <=> NULL FROM employees WHERE id=99;
```

```
?column?
```

```

```

```
t
```

```
(1 row)
```

Empty collections are not null and behave as expected:

```
=> SELECT ARRAY[]::ARRAY[INT] = ARRAY[]::ARRAY[INT];
```

```
?column?
```

```

```

```
t
```

```
(1 row)
```

Collections are compared element by element. If a comparison depends on a null element, the result is unknown (null), not false. For example, `ARRAY[1,2,null]=ARRAY[1,2,null]` and `ARRAY[1,2,null]=ARRAY[1,2,3]` both return null, but `ARRAY[1,2,null]=ARRAY[1,4,null]` returns false because the second elements do not match.

### Casting

Casting an array casts each element of the array. You can therefore cast between data types following the same rules as for casts of scalar values.

You can cast both literal arrays and array columns explicitly:

```
=> SELECT ARRAY['1','2','3']::ARRAY[INT];
```

```
array
```

```

```

```
[1,2,3]
```

```
(1 row)
```

You can change the bound of an array or set by casting. When casting to a bounded native array, inputs that are too long are truncated. When casting to a non-native array (an array containing complex data types including other arrays), if the new bounds are too small for the data the cast fails:

```
=> SELECT ARRAY[1,2,3]::ARRAY[VARCHAR,2];
```

```
array
```

```

```

```
["1","2"]
```

```
(1 row)
```

```
=> SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6]]::ARRAY[ARRAY[VARCHAR,2],2];
```

```
ERROR 9227: Output array isn't big enough
```

```
DETAIL: Type limit is 4 elements, but value has 6 elements
```

If you cast to a bounded multi-dimensional array, you must specify the bounds at all levels:

```
=> SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6]]::ARRAY[ARRAY[VARCHAR,5],10];
```

```
array
```

```

```

```
[[["1","2","3"],["4","5","6"]]
```

```
(1 row)
```

```
=> SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6]]::ARRAY[ARRAY[VARCHAR,2]];
```

```
WARNING 9753: Collection type bound will not be used
```

```
DETAIL: A bound was provided for an inner dimension, but not for an outer dimension
```

```
array
```

```

```

```
[[["1","2","3"],["4","5","6"]]
```

```
(1 row)
```

Assignment casts and implicit casts work the same way as for scalars:

```
=> CREATE TABLE transactions (tid INT, prod_ids ARRAY[VARCHAR,100], quantities ARRAY[INT,100]);
CREATE TABLE

=> INSERT INTO transactions VALUES (12345, ARRAY['p1265', 'p4515'], ARRAY[15,2]);
OUTPUT

 1
(1 row)

=> CREATE TABLE txreport (prod_ids ARRAY[VARCHAR(12),100], quants ARRAY[VARCHAR(32),100]);
CREATE TABLE

=> INSERT INTO txreport SELECT prod_ids, quantities FROM transactions;
OUTPUT

 1
(1 row)

=> SELECT * FROM txreport;
 prod_ids | quants
-----+-----
 ["p1265","p4515"] | ["15","2"]
(1 row)
```

You can perform explicit casts, but not implicit casts, between the ARRAY and [SET](#) types (native arrays only). If the collection is unbounded and the data type does not change, the binary size is preserved. For example, if you cast an ARRAY[INT] to a SET[INT], the set has the same binary size as the array.

If you cast from one element type to another, the resulting collection uses the default binary size. If this would cause the data not to fit, the cast fails.

You cannot cast from an array to an array with a different dimensionality, for example from a two-dimensional array to a one-dimensional array.

Functions and operators

See [Collection functions](#) for a comprehensive list of functions that can be used to manipulate arrays and sets.

Collections can be used in the following ways:

- As the grouping column in a [GROUP BY clause](#).
- For native arrays only, as the sort key in an [ORDER BY clause](#) in a query, in an OVER clause (see [Window partitioning](#)), or in a [CREATE PROJECTION](#) statement.
- As the sort key in the PARTITION BY part of an OVER clause.
- As a JOIN key (see [Joined-table](#)).
- In [CASE expressions](#).

Collections cannot be used in the following ways:

- As part of an IN or NOT IN expression.
- As partition columns when creating tables.
- With ANALYZE\_STATISTICS or TopK projections.
- Non-native arrays only: ORDER BY, PARTITION BY, DEFAULT, SET USING, or constraints.

MAP

Represents map data in external tables in the Parquet, ORC, and Avro formats only. A MAP must use only primitive types and may not contain other complex types. You can use the MAP type in a table definition to consume columns in the data, but you cannot query those columns.

A superior alternative to MAP is [ARRAY \[ ROW \]](#). An array of rows can use all supported complex types and can be queried. This is the representation that [INFER\\_TABLE\\_DDL](#) suggests. For Avro data, the ROW must have fields named **key** and **value**.

Within a single table you must define all map columns using the same approach, MAP or ARRAY[ROW].

Syntax

In column definitions:

```
MAP<key,value>
```

Map input format for column definition

In a column definition in an external table, a MAP consists of a key-value pair, specified as types. The table in the following example defines a map of product IDs to names.

```
=> CREATE EXTERNAL TABLE store (storeID INT, inventory MAP<INT,VARCHAR(100)>)
AS COPY FROM '...' PARQUET;
```

ROW

Represents structured data (structs). A ROW can contain fields of any primitive or complex type supported by Vertica.

Syntax

In [column definitions](#):

```
ROW([field type[, ...]])
```

If the field name is omitted, Vertica generates names starting with "f0".

In [literals](#):

```
ROW(value [AS field] [, ...]) [AS name(field[, ...])]
```

Syntax for column definition

In a column definition, a ROW consists of one or more comma-separated pairs of field names and types. In the following example, the Parquet data file contains a struct for the address, which is read as a ROW in an external table:

```
=> CREATE EXTERNAL TABLE customers (name VARCHAR,
address ROW(street VARCHAR, city VARCHAR, zipcode INT))
AS COPY FROM '...' PARQUET;
```

ROWS can be nested; a field can have a type of ROW:

```
=> CREATE TABLE employees(
employeeID INT,
personal ROW(
name VARCHAR,
address ROW(street VARCHAR, city VARCHAR, zipcode INT),
taxID INT),
department VARCHAR);
```

ROWS can contain arrays:

```
=> CREATE TABLE customers(
name VARCHAR,
contact ROW(
street VARCHAR,
city VARCHAR,
zipcode INT,
email ARRAY[VARCHAR]
),
accountid INT);
```

When loading data, the primitive types in the table definition must match those in the data. The ROW structure must also match; a ROW must contain all and only the fields in the struct in the data.

Restrictions on ROW columns

ROW columns have several restrictions:

- Maximum nesting depth is 100.
- Vertica tables support up to 9800 columns and fields. The ROW itself is not counted, only its fields.
- ROW columns cannot use any constraints (such as NOT NULL) or defaults.
- ROW fields cannot be auto\_increment or setof.

- ROW definition must include at least one field.
- **Row** is a reserved keyword within a ROW definition, but is permitted as the name of a table or column.
- Tables containing ROW columns cannot also contain IDENTITY, default, SET USING, or named sequence columns.

Syntax for direct construction (literals)

In a literal, such as a value in a comparison operation, a ROW consists of one or more values. If you omit field names in the ROW expression, Vertica generates them automatically. If you do not coerce types, Vertica infers the types from the data values.

```
=> SELECT ROW('Amy',2,false);
 row

{"f0":"Amy","f1":2,"f2":false}
(1 row)
```

You can use an AS clause to name the ROW and its fields:

```
=> SELECT ROW('Amy',2,false) AS student(name, id, current);
 student

{"name":"Amy","id":2,"current":false}
(1 row)
```

You can also name individual fields using AS. This query produces the same output as the previous one:

```
=> SELECT ROW('Amy' AS name, 2 AS id, false AS current) AS student;
```

You do not need to name all fields.

In an array of ROW elements, if you use AS to name fields and the names differ among the elements, Vertica uses the right-most names for all elements:

```
=> SELECT ARRAY[ROW('Amy' AS name, 2 AS id),ROW('Fred' AS first_name, 4 AS id)];
 array

[{"first_name":"Amy","id":2},{first_name":"Fred","id":4}]
(1 row)
```

You can coerce types explicitly:

```
=> SELECT ROW('Amy',2.5::int,false::varchar);
 row

{"f0":"Amy","f1":3,"f2":"f"}
(1 row)
```

Escape single quotes in literal inputs using single quotes, as in the following example:

```
=> SELECT ROW('Howard's house',2,false);
 row

{"f0":"Howard's house","f1":2,"f2":false}
(1 row)
```

You can use fields of all scalar types, ROW, and ARRAY, as in the following example:

```
=> SELECT id.name, major, GPA FROM students
WHERE id = ROW('alice',119, ARRAY['alice@example.com','ap16@cs.example.edu']);
name | major | GPA
-----+-----+-----
alice | [{"school":"Science","dept":"CS"}] | 3.8
(1 row)
```

Output format

ROW values are output in JSON format as in the following example.

```
=> CREATE EXTERNAL TABLE customers (name VARCHAR,
 address ROW(street VARCHAR, city VARCHAR, zipcode INT))
 AS COPY FROM '...' PARQUET;

=> SELECT address FROM customers WHERE address.city ='Pasadena';
 address

{"street": "100 Main St Apt 4B", "city": "Pasadena", "zipcode": 91001}
{"street": "100 Main St Apt 4A", "city": "Pasadena", "zipcode": 91001}
{"street": "23 Fifth Ave Apt 8C", "city": "Pasadena", "zipcode": 91001}
{"street": "15 Raymond Dr", "city": "Pasadena", "zipcode": 91003}
(4 rows)
```

The following table specifies the mappings from Vertica data types to JSON data types.

Vertica Type	JSON Type
Integer	Integer
Float	Numeric
Numeric	Numeric
Boolean	Boolean
All others	String

### Comparisons

ROW supports equality ( = ), inequality ( <> ), and null-safe equality ( <=> ) between inputs that have the same set of fields. ROWs that contain only primitive types, including nested ROWs of primitive types, also support comparison operators ( < , <= , > , >= ).

Two ROWs are equal if and only if all fields are equal. Vertica compares fields in order until an inequality is found or all fields have been compared. The evaluation of the first non-equal field determines which ROW is greater:

```
=> SELECT ROW(1, 'joe') > ROW(2, 'bob');
?column?

f
(1 row)
```

Comparisons between ROWs with different schemas fail:

```
=> SELECT ROW(1, 'joe') > ROW(2, 'bob', 123);
ERROR 5162: Unequal number of entries in row expressions
```

If the result of a comparison depends on a null field, the result is null:

```
=> select row(1, null, 3) = row(1, 2, 3);
?column?

(1 row)
```

### Null-handling

If a struct exists but a field value is null, Vertica assigns NULL as its value in the ROW. A struct where all fields are null is treated as a ROW with null fields. If the struct itself is null, Vertica reads the ROW as NULL.

### Casting

Casting a ROW casts each field. You can therefore cast between data types following the same rules as for casts of scalar values.

The following example casts the `contact` ROW in the `customers` table, changing the `zipcode` field from INT to VARCHAR and adding a bound to the array:

```
=> SELECT contact::ROW(VARCHAR, VARCHAR, VARCHAR, ARRAY[VARCHAR,20]) FROM customers;
```

contact

```

{ "street": "911 San Marcos St", "city": "Austin", "zipcode": "73344", "email": ["missy@mit.edu", "mcooper@cern.gov"] }
{ "street": "100 Main St Apt 4B", "city": "Pasadena", "zipcode": "91001", "email": ["shelly@meemaw.name", "cooper@caltech.edu"] }
{ "street": "100 Main St Apt 4A", "city": "Pasadena", "zipcode": "91001", "email": ["hofstadter@caltech.edu"] }
{ "street": "23 Fifth Ave Apt 8C", "city": "Pasadena", "zipcode": "91001", "email": [] }
{ "street": null, "city": "Pasadena", "zipcode": "91001", "email": ["raj@available.com"] }
```

(6 rows)

You can specify new field names to change them in the output:

```
=> SELECT contact::ROW(str VARCHAR, city VARCHAR, zip VARCHAR, email ARRAY[VARCHAR,
20]) FROM customers;
```

contact

```

{ "str": "911 San Marcos St", "city": "Austin", "zip": "73344", "email": ["missy@mit.edu", "mcooper@cern.gov"] }
{ "str": "100 Main St Apt 4B", "city": "Pasadena", "zip": "91001", "email": ["shelly@meemaw.name", "cooper@caltech.edu"] }
{ "str": "100 Main St Apt 4A", "city": "Pasadena", "zip": "91001", "email": ["hofstadter@caltech.edu"] }
{ "str": "23 Fifth Ave Apt 8C", "city": "Pasadena", "zip": "91001", "email": [] }
{ "str": null, "city": "Pasadena", "zip": "91001", "email": ["raj@available.com"] }
```

(6 rows)

Supported operators and predicates

ROW values may be used in queries in the following ways:

- INNER and OUTER JOIN
- [Comparisons](#), IN, BETWEEN (non-nullable filters only)
- IS NULL, IS NOT NULL
- CASE
- GROUP BY, ORDER BY
- SELECT DISTINCT
- Arguments to user-defined scalar, transform, and analytic functions

The following operators and predicates are not supported for ROW values:

- Math operators
- Type coercion of whole rows (coercion of field values is supported)
- BITWISE, LIKE
- MLA (ROLLUP, CUBE, GROUPING SETS)
- Aggregate functions including MAX, MIN, and SUM
- Set operators including UNION, UNION ALL, MINUS, and INTERSECT

COUNT is not supported for ROWs returned from user-defined scalar functions, but is supported for ROW columns and literals.

In comparison operations (including implicit comparisons like ORDER BY), a ROW literal is treated as the sequence of its field values. For example, the following two statements are equivalent:

```
GROUP BY ROW(zipcode, city)
GROUP BY zipcode, city
```

Using rows in views and subqueries

You can use ROW columns to construct views and in subqueries. Consider employee and customer tables with the following definitions:

```
=> CREATE EXTERNAL TABLE customers(name VARCHAR,
 address ROW(street VARCHAR, city VARCHAR, zipcode INT), accountID INT)
 AS COPY FROM '...' PARQUET;
```

```
=> CREATE EXTERNAL TABLE employees(employeeID INT,
 personal ROW(name VARCHAR,
 address ROW(street VARCHAR, city VARCHAR, zipcode INT),
 taxID INT), department VARCHAR)
 AS COPY FROM '...' PARQUET;
```

The following example creates a view and queries it.

```
=> CREATE VIEW neighbors (num_neighbors, area(city, zipcode))
AS SELECT count(*), ROW(address.city, address.zipcode)
FROM customers GROUP BY address.city, address.zipcode;
CREATE VIEW

=> SELECT employees.personal.name, neighbors.area FROM neighbors, employees
WHERE employees.personal.address.zipcode=neighbors.area.zipcode AND neighbors.num_neighbors > 1;

 name | area
-----+-----
Sheldon Cooper | {"city":"Pasadena","zipcode":91001}
Leonard Hofstadter | {"city":"Pasadena","zipcode":91001}
(2 rows)
```

## SET

Represents a collection of unordered, unique elements. Sets may contain only primitive types. In sets, unlike in arrays, element position is not meaningful.

Sets do not support LONG types (like LONG VARBINARY or LONG VARCHAR) or user-defined types (like Geometry).

If you populate a set from an array, Vertica sorts the values and removes duplicate elements. If you do not care about element position and plan to run queries that check for the presence of specific elements (find, contains), using a set could improve query performance.

Sets can be bounded, meaning they specify a maximum element count, or unbounded. Unbounded sets have a maximum binary size, which can be set explicitly or defaulted. See [Limits on Element Count and Collection Size](#).

## Syntax

In [column definitions](#) :

```
SET[data_type, max_elements] |
SET[data_type](max_size) |
SET[data_type]
```

In [literals](#) :

```
SET[value[, ...]]
```

## Restrictions

- Sets support only data of primitive (scalar) types.
- Bounds, if specified, are enforced for all operations that load or alter data. Unbounded sets may have as many elements as will fit in the allotted binary size.
- A set has a maximum binary size. If this size is not set when the set is defined, a default value is used.

## Syntax for column definition

Sets used in column definitions can be either bounded or unbounded. Bounded sets must specify a maximum number of elements. Unbounded sets can specify a maximum binary size for the set, or the value of [DefaultArrayBinarySize](#) is used. You can specify a bound or a binary size but not both. For more information about these values, see [Limits on Element Count and Collection Size](#).

Type	Syntax	Semantics
------	--------	-----------

Bounded set	<p><code>SET[ <i>data_type</i> , <i>max_elements</i> ]</code></p> <p>Example:</p> <p><code>SET[VARCHAR(50),100]</code></p>	<p>Can contain no more than <i>max_elements</i> elements. Attempting to add more is an error.</p> <p>Has a binary size of the size of the data type multiplied by the maximum number of elements (possibly rounded up).</p>
Unbounded set with maximum size	<p><code>SET[ <i>data_type</i> ]( <i>max_size</i> )</code></p> <p>Example:</p> <p><code>SET[VARCHAR(50)](32000)</code></p>	<p>Can contain as many elements as fit in <i>max_size</i> . Ignores the value of <code>DefaultArrayBinarySize</code>.</p>
Unbounded set	<p><code>SET[ <i>data_type</i> ]</code></p> <p>Example:</p> <p><code>SET[VARCHAR(50)]</code></p>	<p>Can contain as many elements as fit in the default binary size.</p> <p>Equivalent to:</p> <p><code>SET[ <i>data_type</i> ](DefaultArrayBinarySize)</code></p>

The following example defines a table with an unbounded set column.

```
=> CREATE TABLE users
(
 user_id INTEGER,
 display_name VARCHAR,
 email_addrs SET[VARCHAR]
);
```

When you load array data into a column defined as a set, the array data is automatically converted to a set.

Syntax for direct construction (literals)

Use the SET keyword to construct a set value. Literal set values are contained in brackets. For example, to create a set of INT, you would do the following:

```
=> SELECT SET[1,2,3];
 set

[1,2,3]
(1 row)
```

You can explicitly convert an array to a set by casting, as in the following example:

```
=> SELECT ARRAY[1, 5, 2, 6, 3, 0, 6, 4]::SET[INT];
 set

[0,1,2,3,4,5,6]
(1 row)
```

Notice that duplicate elements have been removed and the elements have been sorted.

Because the elements are known at the time you directly construct a set, these sets are implicitly bounded.

Output format

Sets are shown in a JSON-like format, with comma-separated elements contained in brackets (like arrays). In the following example, the email\_addrs column is a set.

```
=> SELECT custkey,email_addrs FROM customers LIMIT 4;
custkey | email_addrs
-----+-----
342176 | ["joe.smith@example.com"]
342799 | ["bob@example.com","robert.jones@example.com"]
342845 | ["br92@cs.example.edu"]
342321 | ["789123@example-isp.com","sjohnson@eng.example.com","sara@johnson.example.name"]
```

#### Limits on element count and collection size

When declaring a collection type for a table column, you can limit either the number of elements or the total binary size of the collection. During query processing, Vertica always reserves the maximum memory needed for the column, based on either the element count or the binary size. If this size is much larger than your data actually requires, setting one of these limits can improve query performance by reducing the amount of memory that must be reserved for the column.

You can change the bounds of a collection, including changing between bounded and unbounded collections, by casting. See [Casting](#).

A bounded collection specifies a maximum element count. A value in a bounded collection column may contain fewer elements, but it may not contain more. Any attempt to insert more elements into a bounded collection than the declared maximum is an error. A bounded collection has a binary size that is the product of the data-type size and the maximum number of elements, possibly rounded up.

An unbounded collection specifies a binary size in bytes, explicitly or implicitly. It may contain as many elements as can fit in that binary size.

Instead of specifying a bound, you can specify a maximum binary size for an unbounded collection. The binary size acts as an absolute limit, regardless of how many elements the collection contains. Collections that do not specify a maximum binary size use the value of [DefaultArrayBinarySize](#). This size is set at the time the collection is defined and is not affected by later changes to the value of `DefaultArrayBinarySize`.

You cannot set a maximum binary size for a bounded collection, only an unbounded one.

#### Comparisons

All collections support equality ( = ), inequality ( <> ), and null-safe equality ( <=> ). 1D collections also support comparison operators ( < , <= , > , >= ) between collections of the same type (arrays or sets). Comparisons follow these rules:

- A null collection is ordered last.
- Non-null collections are compared element by element, using the ordering rules of the element's data type. The relative order of the first pair of non-equal elements determines the order of the two collections.
- If all elements in both collections are equal up to the length of the shorter collection, the shorter collection is ordered before the longer one.
- If all elements in both collections are equal and the collections are of equal length, the collections are equal.

#### Null handling

Null semantics for collections are consistent with normal columns in most regards. See [NULL sort order](#) for more information on null-handling.

The null-safe equality operator (<=>) behaves differently from equality (=) when the collection is null rather than empty. Comparing a collection to NULL strictly returns null:

```
=> SELECT ARRAY[1,3] = NULL;
?column?

(1 row)

=> SELECT ARRAY[1,3] <=> NULL;
?column?

f
(1 row)
```

In the following example, the grants column in the table is null for employee 99:

```
=> SELECT grants = NULL FROM employees WHERE id=99;
?column?
```

```

(1 row)
```

```
=> SELECT grants <=> NULL FROM employees WHERE id=99;
?column?
```

```

t
(1 row)
```

Empty collections are not null and behave as expected:

```
=> SELECT ARRAY[]::ARRAY[INT] = ARRAY[]::ARRAY[INT];
?column?
```

```

t
(1 row)
```

Collections are compared element by element. If a comparison depends on a null element, the result is unknown (null), not false. For example, `ARRAY[1,2,null]=ARRAY[1,2,null]` and `ARRAY[1,2,null]=ARRAY[1,2,3]` both return null, but `ARRAY[1,2,null]=ARRAY[1,4,null]` returns false because the second elements do not match.

### Casting

Casting a set casts each element of the set. You can therefore cast between data types following the same rules as for casts of scalar values.

You can cast both literal sets and set columns explicitly:

```
=> SELECT SET['1','2','3']::SET[INT];
set
```

```

[1,2,3]
(1 row)
```

```
=> CREATE TABLE transactions (tid INT, prod_ids SET[VARCHAR], quantities SET[VARCHAR(32)]);
```

```
=> INSERT INTO transactions VALUES (12345, SET['p1265', 'p4515'], SET['15','2']);
```

```
=> SELECT quantities :: SET[INT] FROM transactions;
quantities
```

```

[15,2]
(1 row)
```

Assignment casts and implicit casts work the same way as for scalars.

You can perform explicit casts, but not implicit casts, between [ARRAY](#) and SET types. If the collection is unbounded and the data type does not change, the binary size is preserved. For example, if you cast an `ARRAY[INT]` to a `SET[INT]`, the set has the same binary size as the array.

When casting an array to a set, Vertica first casts each element and then sorts the set and removes duplicates. If two source values are cast to the same target value, one of them will be removed. For example, if you cast an array of `FLOAT` to a set of `INT`, two values in the array might be rounded to the same integer and then be treated as duplicates. This also happens if the array contains more than one value that is cast to `NULL`.

If you cast from one element type to another, the resulting collection uses the default binary size. If this would cause the data not to fit, the cast fails.

### Functions and operators

See [Collection functions](#) for a comprehensive list of functions that can be used to manipulate arrays and sets.

Collections can be used in the following ways:

- As the grouping column in a [GROUP BY clause](#).
- For native arrays only, as the sort key in an [ORDER BY clause](#) in a query, in an `OVER` clause (see [Window partitioning](#)), or in a [CREATE PROJECTION](#) statement.

- As the sort key in the PARTITION BY part of an OVER clause.
- As a JOIN key (see [Joined-table](#)).
- In [CASE expressions](#).

Collections cannot be used in the following ways:

- As part of an IN or NOT IN expression.
- As partition columns when creating tables.
- With ANALYZE\_STATISTICS or TopK projections.
- Non-native arrays only: ORDER BY, PARTITION BY, DEFAULT, SET USING, or constraints.

## Data type mappings between Vertica and Oracle

Oracle uses proprietary data types for all main data types, such as VARCHAR, INTEGER, FLOAT, DATE. Before migrating a database from Oracle to Vertica, first convert the schema to minimize errors and time spent fixing erroneous data issues.

The following table compares the behavior of Oracle data types to Vertica data types.

Oracle	Vertica	Notes
NUMBER  (no explicit precision)	<a href="#">INTEGER</a>	<p>In Oracle, the NUMBER data type with no explicit precision stores each number <math>N</math> as an integer <math>M</math>, together with a scale <math>S</math>. The scale can range from -84 to 127, while the precision of <math>M</math> is limited to 38 digits. Thus:</p> $N = M * 10^S$ <p>When precision is specified, precision/scale applies to all entries in the column. If omitted, the scale defaults to 0.</p> <p>For the common case—Oracle NUMBER with no explicit precision used to store only integer values—the Vertica INTEGER data type is the most appropriate and the fastest equivalent data type. However, INTEGER is limited to a little less than 19 digits, with a scale of 0: <a href="#">[-9223372036854775807, +9223372036854775807]</a>.</p>
	<a href="#">NUMERIC</a>	<p>If an Oracle column contains integer values outside of the range <a href="#">[-9223372036854775807, +9223372036854775807]</a>, then use the Vertica data type NUMERIC(<math>p</math>,0) where <math>p</math> is the maximum number of digits required to represent values of the source data.</p> <p>If the data is exact with fractional places—for example dollar amounts—Vertica recommends NUMERIC(<math>p</math>, <math>s</math>) where <math>p</math> is the precision (total number of digits) and <math>s</math> is the maximum scale (number of decimal places).</p> <p>Vertica conforms to standard SQL, which requires that <math>p \geq s</math> and <math>s \geq 0</math>. Vertica's NUMERIC data type is most effective for <math>p=18</math>, and increasingly expensive for <math>p=37, 58, 67</math>, etc., where <math>p \leq 1024</math>.</p> <div style="background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>Tip</b> Vertica recommends against using the data type NUMERIC(38, <math>s</math>) as a default "failsafe" mapping to guarantee no loss of precision. NUMERIC(18, <math>s</math>) is better, and INTEGER or FLOAT better yet, if one of these data types will do the job.</p> </div>
	<a href="#">FLOAT</a>	<p>Even though no explicit scale is specified for an Oracle NUMBER column, Oracle allows non-integer values, each with its own scale. If the data stored in the column is approximate, Vertica recommends using the Vertica data type FLOAT, which is standard IEEE floating point, like ORACLE BINARY_DOUBLE.</p>
NUMBER( $P$ ,0)  $P \leq 18$	<a href="#">INTEGER</a>	For Oracle NUMBER data types with 0 scale and a precision less than or equal to 18, use the Vertica INTEGER data type.
NUMBER( $P$ ,0)  $P > 18$	<a href="#">NUMERIC</a> ( $p$ ,0)	In the rare case where a Oracle column specifies precision greater than 18, use the Vertica data type NUMERIC( $p$ , 0), where $p = P$ .

NUMBER( <i>P</i> , <i>S</i> ) All cases other than above	<a href="#">NUMERIC</a> ( <i>p</i> , <i>s</i> ) <a href="#">FLOAT</a>	<ul style="list-style-type: none"> <li>When <math>P \geq S</math> and <math>S \geq 0</math>, use <math>p = P</math> and <math>s = S</math>, unless the data allows reducing <math>P</math> or using FLOAT as discussed above.</li> <li>If <math>S &gt; P</math>, use <math>p = S</math>, <math>s = S</math>.</li> <li>If <math>S &lt; 0</math>, use <math>p = P - S</math>, <math>s = 0</math>.</li> </ul>
NUMERIC( <i>P</i> , <i>S</i> )		Rarely used in Oracle, see notes for Oracle <a href="#">NUMBER</a> .
DECIMAL( <i>P</i> , <i>S</i> )		Synonym for Oracle NUMERIC.
BINARY_FLOAT	<a href="#">FLOAT</a>	Same as FLOAT(53) or DOUBLE PRECISION
BINARY_DOUBLE	<a href="#">FLOAT</a>	Same as FLOAT(53) or DOUBLE PRECISION
RAW	<a href="#">VARBINARY</a>	Maximum sizes compared: <ul style="list-style-type: none"> <li>Oracle RAW data type: 2000 bytes</li> <li>Vertica VARBINARY: 65000 bytes</li> </ul>
LONG RAW	<a href="#">LONG VARBINARY</a>	Maximum sizes compared: <ul style="list-style-type: none"> <li>Oracle's LONG RAW is 2GB</li> <li>Vertica LONG VARBINARY is 32M bytes/octetes (~30MB)</li> </ul> <div style="background-color: #ffe6e6; padding: 10px; margin-top: 10px;"> <p><b>Caution</b> Be careful to avoid truncation when migrating Oracle LONG RAW data to Vertica.</p> </div>
CHAR( <i>n</i> )	<a href="#">CHAR</a> ( <i>n</i> )	Maximum sizes compared: <ul style="list-style-type: none"> <li>Oracle CHAR: 2000 bytes</li> <li>Vertica CHAR : 65000 bytes</li> </ul>
NCHAR( <i>n</i> )	<a href="#">CHAR</a> ( <i>n**3</i> )	Vertica supports national characters with CHAR( <i>n</i> ) as variable-length UTF8-encoded UNICODE character string. UTF-8 represents ASCII in 1 byte, most European characters in 2 bytes, and most oriental and Middle Eastern characters in 3 bytes.
VARCHAR2( <i>n</i> )	<a href="#">VARCHAR</a> ( <i>n</i> )	Maximum sizes compared: <ul style="list-style-type: none"> <li>Oracle VARCHAR2: 4000 bytes</li> <li>Vertica VARCHAR: 65000 bytes</li> </ul> <p>Important The Oracle VARCHAR2 and Vertica VARCHAR data types are semantically different:</p> <ul style="list-style-type: none"> <li>VARCHAR exhibits standard SQL behavior</li> <li>VARCHAR2 is inconsistent with standard SQL behavior in that it treats an empty string as NULL value, and uses non-padded comparison if one operand is VARCHAR2.</li> </ul>
NVARCHAR2( <i>n</i> )	<a href="#">VARCHAR</a> ( <i>n**3</i> )	See notes for <a href="#">NCHAR</a> .
DATE	<a href="#">TIMESTAMP</a> <a href="#">DATE</a>	Oracle's DATE is different from the SQL standard DATE data type implemented by Vertica. Oracle's DATE includes the time (no fractional seconds), while Vertica DATE data types include only date as per the SQL standard.

TIMESTAMP	<a href="#">TIMESTAMP</a>	TIMESTAMP defaults to six places—that is, to microseconds.
TIMESTAMP WITH TIME ZONE	<a href="#">TIMESTAMP WITH TIME ZONE</a>	TIME ZONE defaults to the currently SET or system time zone.
INTERVAL YEAR TO MONTH	<a href="#">INTERVAL YEAR TO MONTH</a>	As per the SQL standard, you can qualify Vertica INTERVAL data types with the YEAR TO MONTH subtype.
INTERVAL DAY TO SECOND	<a href="#">INTERVAL DAY TO SECOND</a>	The default subtype for Vertica INTERVAL data types is DAY TO SECOND.
CLOB	<a href="#">LONG VARCHAR</a>	You can store a CLOB (character large object) or BLOB (binary large object) value in a table or in an external location. The maximum size of a CLOB or BLOB is 128 TB.
BLOB	<a href="#">LONG VARBINARY</a>	You can store Vertica LONG data types only in LONG VARCHAR and LONG VARBINARY columns. The maximum size of LONG data types is 32M bytes.
LONG	<a href="#">LONG VARCHAR</a>	Oracle recommends using CLOB and BLOB data types instead of LONG and LONG RAW data types.
LONG RAW	<a href="#">LONG VARBINARY</a>	An Oracle table can contain only one LONG column, The maximum size of a LONG or LONG RAW data type is 2 GB.

## Configuration parameters

Vertica supports a wide variety of configuration parameters that affect many facets of database behavior. These parameters can be set with the appropriate ALTER statements at one or more levels, listed here in descending order of precedence:

1. User ( [ALTER USER](#) )
2. Session ( [ALTER SESSION](#) )
3. Node ( [ALTER NODE](#) )
4. Database ( [ALTER DATABASE](#) )

Not all parameters can be set at all levels. Consult the documentation of individual parameters for restrictions.

You can query the [CONFIGURATION\\_PARAMETERS](#) system table to obtain the current settings for all user-accessible parameters. For example, the following query returns settings for partitioning parameters: their current and default values, which levels they can be set at, and whether changes require a database restart to take effect:

```

=> SELECT parameter_name, current_value, default_value, allowed_levels, change_requires_restart
 FROM configuration_parameters WHERE parameter_name ILIKE '%partitioncount%';
parameter_name | current_value | default_value | allowed_levels | change_requires_restart

MaxPartitionCount | 1024 | 1024 | NODE, DATABASE | f
ActivePartitionCount | 1 | 1 | NODE, DATABASE | f
(2 rows)

```

## General parameters

The following parameters configure basic database operations. Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### ApplyEventsDuringSALCheck

Boolean, specifies whether Vertica uses catalog events to filter out dropped corrupt partitions during node startup. Dropping corrupt partitions can speed node recovery.

When disabled (0), Vertica reports corrupt partitions, but takes no action. Leaving corrupt partitions in place can reset the current projection checkpoint epoch to the epoch before the corruption occurred.

This parameter has no effect on unpartitioned tables.

**Default:** 0

### ApportionedFileMinimumPortionSizeKB

Specifies the minimum portion size (in kilobytes) for use with apportioned file loads. Vertica apportions a file load across multiple nodes only if:

- The load can be divided into portions at least equaling this value.
- EnableApportionedFileLoad and EnableApportionLoad are set to 1 (enabled).

See also EnableApportionLoad and EnableApportionedFileLoad.

**Default:** 1024

### BlockedSocketGracePeriod

Sets how long a session socket remains blocked while awaiting client input or output for a given query. See [Handling session socket blocking](#).

**Default:** None (Socket blocking can continue indefinitely.)

### CatalogCheckpointPercent

Specifies the threshold at which a checkpoint is created for the database catalog.

By default, this parameter is set to 50 (percent), so when transaction logs reach 50% of the size of the last checkpoint, Vertica adds a checkpoint. Each checkpoint demarcates all changes to the catalog since the last checkpoint.

**Default:** 50 (percent)

### ClusterSequenceCacheMode

Boolean, specifies whether the initiator node requests cache for other nodes in a cluster, and then sends cache to other nodes along with the execution plan, one of the following.

- 1 (enabled): Initiator node requests cache.
- 0 (disabled): All nodes request their own cache.

See [Distributing sequences](#).

**Default:** 1 (enabled)

### CompressCatalogOnDisk

Whether to compress the size of the catalog on disk, one of the following:

- 0: Do not compress.
- 1: Compress checkpoints, but not logs.
- 2: Compress checkpoints and logs.

This parameter is most effective if the catalog disk partition is small (<50 GB) and the metadata is large (hundreds of tables, partitions, or nodes).

**Default:** 1

### **CompressNetworkData**

Boolean, specifies whether to compress all data sent over the internal network when enabled (set to 1). This compression speeds up network traffic at the expense of added CPU load. If the network is throttling database performance, enable compression to correct the issue.

**Default:** 0

### **CopyFaultTolerantExpressions**

Boolean, indicates whether to report record rejections during transformations and proceed (true) or abort COPY operations if a transformation fails.

**Default:** 0 (false)

### **CopyFromVerticaWithIdentity**

Allows [COPY FROM VERTICA](#) and [EXPORT TO VERTICA](#) to load values into [IDENTITY](#) columns. The destination IDENTITY column is not incremented automatically. To disable the default behavior, set this parameter to 0 (zero).

**Default:** 1

### **DatabaseHeartbeatInterval**

Determines the interval (in seconds) at which each node performs a health check and communicates a heartbeat. If a node does not receive a message within five times of the specified interval, the node is evicted from the cluster. Setting the interval to 0 disables the feature.

See [Automatic eviction of unhealthy nodes](#).

**Default:** 120

### **DataLoaderDefaultRetryLimit**

Default number of times a [data loader](#) retries failed loads. Changing this value changes the retry limit for existing data loaders that do not specify another limit.

**Default:** 3

### **DefaultArrayBinarySize**

The maximum binary size, in bytes, for an unbounded collection, if a maximum size is not specified at creation time.

**Default:** 65000

### **DefaultResourcePoolForUsers**

Resource pool that is assigned to the profile of a new user, whether [created in Vertica](#) or LDAP. This pool is also assigned to users when their assigned resource pool is dropped.

You can set DefaultResourcePoolForUsers only to a global resource pool; attempts to set it to a subcluster resource pool return with an error.

#### **Note**

If an LDAP user is merged with an existing Vertica user, the resource pool setting on the existing user remains unchanged.

For details, see [User resource allocation](#).

**Default:** [GENERAL](#)

### **DefaultTempTableLocal**

Boolean, specifies whether [CREATE TEMPORARY TABLE](#) creates a local or global temporary table, one of the following:

- 0: Create global temporary table.
- 1: Create local temporary table.

For details, see [Creating temporary tables](#).

**Default:** 0

### **DivideZeroByZeroThrowsError**

Boolean, specifies whether to return an error if a division by zero operation is requested:

- 0: Return 0.
- 1: Returns an error.

**Default:** 1

### EnableApportionedChunkingInDefaultLoadParser

Boolean, specifies whether to enable the built-in parser for delimited files to take advantage of both apportioned load and cooperative parse for potentially better performance.

**Default:** 1 (enable)

### EnableApportionedFileLoad

Boolean, specifies whether to enable automatic apportioning across nodes of file loads using [COPY FROM VERTICA](#). Vertica attempts to apportion the load if:

- This parameter and [EnableApportionLoad](#) are both enabled.
- The parser supports apportioning.
- The load is divisible into portion sizes of at least the value of `ApportionedFileMinimumPortionSizeKB`.

Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be. See [Distributing a load](#).

**Default:** 1 (enable)

### EnableApportionLoad

Boolean, specifies whether to enable automatic apportioning across nodes of data loads using [COPY...WITH SOURCE](#). Vertica attempts to apportion the load if:

- This parameter is enabled.
- The source and parser both support apportioning.

Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be. For details, see [Distributing a load](#).

**Default:** 1 (enable)

### EnableBetterFlexTypeGuessing

Boolean, specifies whether to enable more accurate type guessing when assigning data types to non-string keys in a flex table `__raw__` column with [COMPUTE\\_FLEXTABLE\\_KEYS](#) or [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#). If this parameter is disabled (0), Vertica uses a limited set of Vertica data type assignments.

**Default:** 1 (enable)

### EnableCooperativeParse

Boolean, specifies whether to implement multi-threaded parsing capabilities on a node. You can use this parameter for both delimited and fixed-width loads.

**Default:** 1 (enable)

### EnableForceOuter

Boolean, specifies whether Vertica uses a table's `force_outer` value to implement a join. For more information, see [Controlling join inputs](#).

**Default:** 0 (forced join inputs disabled)

### EnableMetadataMemoryTracking

Boolean, specifies whether to enable Vertica to track memory used by database metadata in the [METADATA resource pool](#).

**Default:** 1 (enable)

### EnableResourcePoolCPUAffinity

Boolean, specifies whether Vertica aligns queries to the resource pool of the processing CPU. When disabled (0), queries run on any CPU, regardless of the `CPU_AFFINITY_SET` of the resource pool.

**Default:** 1

### EnableStrictTimeCasts

Specifies whether all [cast failures](#) result in an error.

**Default:** 0 (disable)

### EnableUniquenessOptimization

Boolean, specifies whether to enable query optimization that is based on guaranteed uniqueness of column values. Columns that can be guaranteed to include unique values include:

- Columns that are defined with [IDENTITY](#) constraints
- Primary key columns where [key constraints are enforced](#)
- Columns that are [constrained to unique values](#), either individually or as a set

**Default:** 1 (enable)

### EnableWithClauseMaterialization

Superseded by [WithClauseMaterialization](#).

### ExternalTablesExceptionsLimit

Determines the maximum number of **COPY** exceptions and rejections allowed when a **SELECT** statement references an external table. Set to **1** to remove any exceptions limit. See [Querying external tables](#).

**Default:** 100

### FailoverToStandbyAfter

Specifies the length of time that an active standby node waits before taking the place of a failed node.

This parameter is set to an [interval literal](#).

**Default:** None

### FencedUDxMemoryLimitMB

Sets the maximum amount of memory, in megabytes (MB), that a fenced-mode **UDF** can use. If a UDF attempts to allocate more memory than this limit, that attempt triggers an exception. For more information, see [Fenced and unfenced modes](#).

**Default:** -1 (no limit)

### FlexTableDataTypeGuessMultiplier

Specifies a multiplier that the **COMPUTE\_FLEXTABLE\_KEYS** and **COMPUTE\_FLEXTABLE\_KEYS\_AND\_BUILD\_VIEW** functions use when assigning a data type and column width for the flex keys table. Both functions assign each key a data type, and multiply the longest key value by this factor to estimate column width. This value is not used to calculate the width of any real columns in a flex table.

**Default:** 2.0

### FlexTableRowSize

Specifies the default column width for the `__raw__` column of new flex tables, a value between 1 and 32000000, inclusive.

**Default:** 130000

### ForceUDxFencedMode

When enabled (1), forces all UDxs that support fenced mode to run in fenced mode even if their definitions specify NOT FENCED.

[File exporters](#) cannot be run in fenced mode.

**Default:** 0

### HTTPServerPortOffset

Controls the offset for the [HTTPS](#) port. The default HTTPS port is 8443, the sum of the client port (5433) and default HTTPServerPortOffset (3010).

#### Caution

This parameter should not be changed without support guidance.

**Default:** 3010

### HTTPSlowRequestThreshold

Threshold in milliseconds for logging HTTP requests in [UDFS\\_EVENTS](#). Requests that take longer than this value are logged; faster ones are not.

**Default:** 500

### IcebergPathMapping

For external tables using Iceberg data, a map of URI prefixes used by Iceberg to prefixes accessible to Vertica. The value is a JSON object:

```
{ "source-prefix": "new-prefix" [, ...] }
```

Specify prefixes only (up through port number), not complete paths.

### IdleTimeoutInitializingConnectionsMs

The length of time (in milliseconds) that the server waits before timing out, during each step in connection initialization. After connection initialization, the session is created.

**Default :** 10000

### JavaBinaryForUDx

Sets the full path to the Java executable that Vertica uses to run Java UDxs. See [Installing Java on Vertica hosts](#).

### JoinDefaultTupleFormat

Specifies how to size VARCHAR column data when joining tables on those columns, and buffers accordingly, one of the following:

- **fixed** : Use join column metadata to size column data to a fixed length, and buffer accordingly.
- **variable** : Use the actual length of join column data, so buffer size varies for each join.

**Default:** **fixed**

### KeepAliveIdleTime

Length (in seconds) of the idle period before the first TCP keepalive probe is sent to ensure that the client is still connected. If set to 0, Vertica uses the kernel's tcp\_keepalive\_time parameter setting.

**Default:** 0

### KeepAliveProbeCount

Number of consecutive keepalive probes that must go unacknowledged by the client before the client connection is considered lost and closed. If set to 0, Vertica uses the kernel's tcp\_keepalive\_probes parameter setting.

**Default:** 0

### KeepAliveProbeInterval

Time interval (in seconds) between keepalive probes. If set to 0, Vertica uses the kernel's tcp\_keepalive\_intvl parameter setting.

**Default:** 0

### LockTimeout

Specifies in seconds how long a table waits to acquire a lock.

**Default:** 300

### LoadSourceStatisticsLimit

Specifies the maximum number of sources per load operation that are profiled in the [LOAD\\_SOURCES](#) system table. Set it to 0 to disable profiling.

**Default:** 256

### MaxBundleableROSSizeKB

Specifies the minimum size, in kilobytes, of an independent ROS file. Vertica bundles storage container ROS files below this size into a single file. Bundling improves the performance of any file-intensive operations, including backups, restores, and mergeouts.

If you set this parameter to a value of 0, Vertica bundles .fdb and .pidx files without bundling other storage container files.

**Default:** 1024

### MaxClientSessions

Determines the maximum number of client sessions that can run on a single node of the database. The default value allows for five additional administrative logins. These logins prevent DBAs from being locked out of the system if non-dbadmin users reach the login limit.

#### Tip

Setting this parameter to 0 prevents new client sessions from being opened while you are shutting down the database. Restore the parameter to its original setting after you restart the database. For details, see [Managing Sessions](#).

**Default:** 50 user logins and 5 additional administrative logins

### ObjectStoreGlobStrategy

For partitioned external tables in object stores, the strategy to use for expanding globs before pruning partitions:

- **Flat** : COPY fetches a list of all full object names with a given prefix, which can incur latency if partitions are numerous or deeply nested.
- **Hierarchical** : COPY fetches object names one partition layer at a time, allowing earlier pruning but possibly requiring more calls to the object store when queries are not selective or there are not many partition directory levels.

For details, see [Partitions on Object Stores](#).

**Default:** Flat

### ObjStoreUploadParallelism

Integer (maximum 1000), size of the thread pool used when writing files to S3. Using more threads parallelizes uploads, but uses more memory. Each node has a single thread pool used for all file writes.

This configuration parameter can be set only at the database level.

**Default:** 0 (disabled)

### ParquetMetadataCacheSizeMB

Size of the cache used for metadata when reading Parquet data. The cache uses local TEMP storage.

**Default:** 4096

### PatternMatchingUsejit

Boolean, specifies whether to enable just-in-time compilation (to machine code) of regular expression pattern matching functions used in queries. Enabling this parameter can usually improve pattern matching performance on large tables. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.

See also [Regular expression functions](#).

**Default:** 1 (enable)

### PatternMatchStackAllocator

Boolean, specifies whether to override the stack memory allocator for the pattern-match library. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.

See also [Regular expression functions](#).

**Default:** 1 (enable override)

### TerraceRoutingFactor

Specifies whether to enable or disable terrace routing on any Enterprise Mode large cluster that implements rack-based fault groups.

- To enable, set as follows:

$$\text{TerraceRoutingFactor} < \frac{(\text{numRackNodes} - 1) + (\text{numRacks} - 1)}{(\text{numRacks} * \text{numRackNodes}) - 1}$$
 where: \* *numRackNodes*: Number of nodes in a rack \* *numRacks*: Number of racks in the cluster

- To disable, set to a value so large that terrace routing cannot be enabled for the largest clusters—for example, 1000.

For details, see [Terrace routing](#).

**Default:** 2

### TransactionIsolationLevel

Changes the isolation level for the database. After modification, Vertica uses the new transaction level for every new session. Existing sessions and their transactions continue to use the original isolation level.

See also [Change transaction isolation levels](#).

**Default:** READ COMMITTED

### TransactionMode

Whether transactions are in read/write or read-only modes. Read/write is the default. Existing sessions and their transactions continue to use the original isolation level.

**Default:** READ WRITE

### UDFSSlowRequestThreshold

Threshold in milliseconds for logging events in [UDFS\\_EVENTS](#). Requests that take longer than this value are logged; faster ones are not.

**Default:** 1000

### UDxFencedBlockTimeout

Number of seconds to wait for output before aborting a UDx running in [Fenced and unfenced modes](#). If the server aborts a UDx for this reason, it produces an error message similar to "ERROR 3399: Failure in UDx RPC call: timed out in receiving a UDx message". If you see this error frequently, you can increase this limit. UDxs running in fenced mode do not run in the server process, so increasing this value does not impede server performance.

**Default:** 60

### UseLocalTzForParquetTimestampConversion

Boolean, specifies whether to do timezone conversion when reading Parquet files. Hive version 1.2.1 introduced an option to localize timezones when writing Parquet files. Previously it wrote them in UTC and Vertica adjusted the value when reading the files.

Set to 0 if Hive already adjusted the timezones.

**Default:** 1 (enable conversion)

### UseServerIdentityOverUserIdentity

Boolean, specifies whether to ignore user-supplied credentials for non-Linux file systems and always use a USER storage location to govern access to data. See [Creating a Storage Location for USER Access](#).

**Default:** 0 (disable)

## WithClauseMaterialization

Boolean, specifies whether to enable [materialization of WITH clause](#) results. When materialization is enabled (1), Vertica evaluates each WITH clause once and stores results in a temporary table.

For WITH queries with complex types, temp relations are disabled.

### Note

You can enable materialization of a given WITH clause with the hint [ENABLE\\_WITH\\_CLAUSE\\_MATERIALIZATION](#).

**Default:** 0 (disable)

## WithClauseRecursionLimit

Specifies the maximum number of times a [WITH RECURSIVE clause](#) iterates over the content of its own result set before it exits. For details, see [WITH clause recursion](#).

Important

Be careful to set WithClauseRecursionLimit only as high as needed to traverse the deepest hierarchies. Vertica sets no limit on this parameter; however, a high value can incur considerable overhead that adversely affects performance and exhausts system resources.

If a high recursion count is required, then consider enabling materialization. For details, see [WITH RECURSIVE Materialization](#).

**Default:** 8

## Azure parameters

Use the following parameters to configure reading from Azure blob storage. For more information about reading data from Azure, see [Azure Blob Storage object store](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### AzureStorageCredentials

Collection of JSON objects, each of which specifies connection credentials for one endpoint. This parameter takes precedence over Azure managed identities.

The collection must contain at least one object and may contain more. Each object must specify at least one of `accountName` or `blobEndpoint`, and at least one of `accountKey` or `sharedAccessSignature`.

- `accountName` : If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint` : Host name with optional port ( `host:port` ). If not specified, uses `account.blob.core.windows.net`.
- `accountKey` : Access key for the account or endpoint.
- `sharedAccessSignature` : Access token for finer-grained access control, if being used by the Azure endpoint.

### AzureStorageEndpointConfig

Collection of JSON objects, each of which specifies configuration elements for one endpoint. Each object must specify at least one of `accountName` or `blobEndpoint`.

- `accountName` : If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint` : Host name with optional port ( `host:port` ). If not specified, uses `account.blob.core.windows.net`.
- `protocol` : HTTPS (default) or HTTP.
- `isMultiAccountEndpoint` : true if the endpoint supports multiple accounts, false otherwise (default is false). To use multiple-account access, you must include the account name in the URI. If a URI path contains an account, this value is assumed to be true unless explicitly set to false.

## Constraints parameters

The following configuration parameters control how Vertica evaluates and enforces constraints. All parameters are set at the database level through [ALTER DATABASE](#).

Three of these parameters—`EnableNewCheckConstraintsByDefault`, `EnableNewPrimaryKeysByDefault`, and `EnableNewUniqueKeysByDefault`—can be used to enforce CHECK, PRIMARY KEY, and UNIQUE constraints, respectively. For details, see [Constraint enforcement](#).

### **EnableNewCheckConstraintsByDefault**

Boolean parameter, set to 0 or 1:

- 0: Disable enforcement of new CHECK constraints except where the table DDL explicitly enables them.
- 1 (default): Enforce new CHECK constraints except where the table DDL explicitly disables them.

### **EnableNewPrimaryKeysByDefault**

Boolean parameter, set to 0 or 1:

- 0 (default): Disable enforcement of new PRIMARY KEY constraints except where the table DDL explicitly enables them.
- 1: Enforce new PRIMARY KEY constraints except where the table DDL explicitly disables them.

#### **Note**

Vertica recommends enforcing constraints PRIMARY KEY and UNIQUE together.

### **EnableNewUniqueKeysByDefault**

Boolean parameter, set to 0 or 1:

- 0 (default): Disable enforcement of new UNIQUE constraints except where the table DDL explicitly enables them.
- 1: Enforce new UNIQUE constraints except where the table DDL explicitly disables them.

### **MaxConstraintChecksPerQuery**

Sets the maximum number of constraints that [ANALYZE\\_CONSTRAINTS](#) can handle with a single query:

- -1 (default): No maximum set, [ANALYZE\\_CONSTRAINTS](#) uses a single query to evaluate all constraints within the specified scope.
- Integer > 0: The maximum number of constraints per query. If the number of constraints to evaluate exceeds this value, [ANALYZE\\_CONSTRAINTS](#) handles it with multiple queries.

For details, see [Distributing Constraint Analysis](#).

## Database Designer parameters

The following table describes the parameters for configuring the Vertica Database Designer.

### **DBDCorrelationSampleRowCount**

Minimum number of table rows at which Database Designer discovers and records correlated columns.

**Default:** 4000

### **DBDLogInternalDesignProcess**

Enables or disables Database Designer logging.

**Default:** 0 (False)

### **DBDUseOnlyDesignerResourcePool**

Enables use of the DBD pool by the Vertica Database Designer.

When set to false, design processing is mostly contained by the user's resource pool, but might spill over into some system resource pools for less-intensive tasks

**Default:** 0 (False)

## Eon Mode parameters

The following parameters configure how the database operates when running in Eon Mode. Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### **BackgroundDepotWarming**

Specifies background depot warming behavior:

- 1: The depot loads objects while it is warming, and continues to do so in the background after the node becomes active and starts executing queries.
- 0: Node activation is deferred until the depot fetches and loads all queued objects

For details, see [Depot Warming](#).

**Default:** 1

### **CatalogSyncInterval**

Specifies in minutes how often the transaction log sync service syncs metadata to communal storage. If you change this setting, Vertica restarts

the interval count.

**Default:** 5

### DelayForDeletes

Specifies in hours how long to wait before deleting a file from communal storage. Vertica first deletes a file from the depot. After the specified time interval, the delete also occurs in communal storage.

**Default:** 0. Deletes the file from communal storage as soon as it is not in use by shard subscribers.

### DepotOperationsForQuery

Specifies behavior when the depot does not contain queried file data, one of the following:

- **ALL** (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
- **FETCHES** : Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
- **NONE** : Do not fetch file data to the depot, read the queried data directly from communal storage.

You can also specify query-level behavior with the hint [DEPOT\\_FETCH](#).

### ECSMode

String parameter that sets the strategy Vertica uses when dividing the data in a shard among subscribing nodes during an ECS-enabled query, one of the following:

- **AUTO** : Optimizer automatically determines the strategy to use.
- **COMPUTE\_OPTIMIZED** : Force use of the compute-optimized strategy.
- **IO\_OPTIMIZED** : Force use of the I/O-optimized strategy.

For details, see [Manually choosing an ECS strategy](#).

**Default:** **AUTO**

### ElasticKSafety

Boolean parameter that controls whether Vertica adjusts shard subscriptions due to the loss of a [primary node](#):

- 1: When a primary node is lost, Vertica subscribes other primary nodes to the down node's shard subscriptions. This action helps reduce the chances of a database into going read-only mode due to loss of shard coverage.
- 0 : Vertica does not change shard subscriptions in reaction to the loss of a primary node.

**Default:** 1

For details, see [Maintaining Shard Coverage](#).

### EnableDepotWarmingFromPeers

Boolean parameter, specifies whether Vertica warms a node depot while the node is starting up and not ready to process queries:

- 1: Warm the depot while a node comes up.
- 0: Warm the depot only after the node is up.

For details, see [Depot Warming](#).

**Default:** 0

### FileDeletionServiceInterval

Specifies in seconds the interval between each execution of the reaper cleaner service task.

**Default:** 60 seconds

### MaxDepotSizePercent

An integer value that specifies the maximum size of the depot as a percentage of disk size,

**Default:** 80

### PreFetchPinnedObjectsToDepotAtStartup

If enabled (set to 1), a warming depot fetches objects that are pinned on its subcluster. For details, see [Depot Warming](#).

**Default:** 0

### ReaperCleanupTimeoutAtShutdown

Specifies in seconds how long Vertica waits for the reaper to delete files from communal storage before shutting down. If set to a negative value, Vertica shuts down without waiting for the reaper.

#### Note

The reaper is a service task that deletes disk files.

**Default:** 300

### **StorageMergeMaxTempCacheMB**

The size of temp space allocated per query to the StorageMerge operator for caching the data of S3 storage containers.

#### **Note**

The actual temp space that is allocated is the lesser of:

- StorageMergeMaxTempCacheMB
- A user's [TEMPSPACECAP](#) setting
- The session [TEMPSPACECAP](#) setting

For details, see [Local caching of storage containers](#).

### **UseCommunalStorageForBatchDepotWarming**

Boolean parameter, specifies whether where a node retrieves data when warming its depot:

- 1: Retrieve data from communal storage.
- 0: Retrieve data from a peer.

#### **Note**

The actual temp space that is allocated is the lesser of two settings:

**Default:** 1

Important

This parameter is for internal use only. Do not change it unless directed to do so by Vertica support.

### **UseDepotForReads**

Boolean parameter, specifies whether Vertica accesses the depot to answer queries, or accesses only communal storage:

- 1: Vertica first searches the depot for the queried data; if not there, Vertica fetches the data from communal storage for this and future queries.
- 0: Vertica bypasses the depot and always obtains queried data from communal storage.

#### **Note**

Enable depot reads to improve query performance and support K-safety.

**Default:** 1

### **UseDepotForWrites**

Boolean parameter, specifies whether Vertica writes loaded data to the depot and then uploads files to communal storage:

- 1: Write loaded data to the depot, upload files to communal storage.
- 0: Bypass the depot and always write directly to communal storage.

**Default:** 1

### **UsePeerToPeerDataTransfer**

Boolean parameter, specifies whether Vertica pushes loaded data to other shard subscribers:

- 1: Send loaded data to all shard subscribers.
- 0: Do not push data to other shard subscribers.

#### **Note**

Setting to 1 helps improve performance when a node is down.

**Default:** 0

Important

This parameter is for internal use only. Do not change it unless directed to do so by Vertica support.

## Epoch management parameters

The following table describes the epoch management parameters for configuring Vertica.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### AdvanceAHMInterval

Determines how frequently (in seconds) Vertica checks the history retention status.

AdvanceAHMInterval cannot be set to a value that is less than the EpochMapInterval.

**Default:** 180 (seconds)

### AHMBackupManagement

Blocks the advancement of the Ancient History Mark (AHM). When this parameter is enabled, the AHM epoch cannot be later than the epoch of your latest full backup. If you advance the AHM to purge and delete data, do not enable this parameter.

#### Caution

Do not enable this parameter before taking full backups, as it would prevent the AHM from advancing.

**Default:** 0

### EpochMapInterval

Determines the granularity of mapping between epochs and time available to [historical queries](#). When a historical queries **AT TIME T** request is issued, Vertica maps it to an epoch within a granularity of EpochMapInterval seconds. It similarly affects the time reported for [Last Good Epoch](#) during [Failure recovery](#). Note that it does not affect internal precision of epochs themselves.

#### Tip

Decreasing this interval increases the number of epochs saved on disk. Therefore, consider reducing the HistoryRetentionTime parameter to limit the number of history epochs that Vertica retains.

**Default:** 180 (seconds)

### HistoryRetentionTime

Determines how long deleted data is saved (in seconds) as an historical reference. When the specified time since the deletion has passed, you can purge the data. Use the -1 setting if you prefer to use [HistoryRetentionEpochs](#) to determine which deleted data can be purged.

#### Note

The default setting of 0 effectively prevents the use of the [Administration tools](#) 'Roll Back Database to Last Good Epoch' option because the [AHM](#) remains close to the current epoch and a rollback is not permitted to an epoch prior to the AHM.

#### Tip

If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data. For example:

```
ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;
```

**Default:** 0 (Data saved when nodes are down.)

### HistoryRetentionEpochs

Specifies the number of historical [epochs](#) to save, and therefore, the amount of deleted data.

Unless you have a reason to limit the number of epochs, Vertica recommends that you specify the time over which deleted data is saved. If you specify both [History](#) parameters, [HistoryRetentionTime](#) takes precedence. Setting both parameters to -1, preserves all historical data.

See [Setting a purge policy](#).

**Default:** -1 (disabled)

## Google Cloud Storage parameters

Use the following parameters to configure reading from Google Cloud Storage (GCS) using COPY FROM. For more information about reading data from S3, see [Specifying where to load data from](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### GCSAuth

An ID and secret key to authenticate to GCS. You can set parameters globally and for the current session with [ALTER DATABASE...SET PARAMETER](#) and [ALTER SESSION...SET PARAMETER](#), respectively. For extra security, do not store credentials in the database; instead, set it for the current session with ALTER SESSION. For example:

```
=> ALTER SESSION SET GCSAuth='ID:secret';
```

If you use a shared credential, set it in the database with ALTER DATABASE.

### GCSEnableHttps

Specifies whether to use the HTTPS protocol when connecting to GCS, can be set only at the database level with [ALTER DATABASE...SET PARAMETER](#).

**Default:** 1 (enabled)

### GCSEndpoint

The connection endpoint address.

**Default:** [storage.googleapis.com](https://storage.googleapis.com)

## Hadoop parameters

The following table describes general parameters for configuring integration with Apache Hadoop. See [Apache Hadoop integration](#) for more information.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### EnableHDFSBlockInfoCache

Boolean, whether to distribute block location metadata collected during planning on the initiator to all database nodes for execution. Distributing this metadata reduces name node accesses, and thus load, but can degrade database performance somewhat in deployments where the name node isn't contended. This performance effect is because the data must be serialized and distributed. Enable distribution if protecting the name node is more important than query performance; usually this applies to large HDFS clusters where name node contention is already an issue.

**Default:** 0 (disabled)

### HadoopConfDir

Directory path containing the XML configuration files copied from Hadoop. The same path must be valid on every Vertica node. You can use the [VERIFY\\_HADOOP\\_CONF\\_DIR](#) meta-function to test that the value is set correctly. Setting this parameter is required to read data from HDFS.

For all Vertica users, the files are accessed by the Linux user under which the Vertica server process runs. When you set this parameter, previously-cached configuration information is flushed.

You can set this parameter at the session level. Doing so overrides the database value; it does not append to it. For example:

```
=> ALTER SESSION SET HadoopConfDir='/test/conf:/hadoop/hcat/conf';
```

To append, get the current value and include it on the new path after your additions. Setting this parameter at the session level does not change how the files are accessed.

**Default:** obtained from environment if possible

### HadoopFSAuthentication

How (or whether) to use Kerberos authentication with HDFS. By default, if KerberosKeytabFile is set, Vertica uses that credential for both Vertica and HDFS. Usually this is the desired behavior. However, if you are using a Kerberized Vertica cluster with a non-Kerberized HDFS cluster, set this parameter to "none" to indicate that Vertica should not use the Vertica Kerberos credential to access HDFS.

**Default:** "keytab" if KerberosKeytabFile is set, otherwise "none"

### HadoopFSBlockSizeBytes

Block size to write to HDFS. Larger files are divided into blocks of this size.

**Default:** 64MB

### HadoopFSNNOperationRetryTimeout

Number of seconds a metadata operation (such as list directory) waits for a response before failing. Accepts float values for millisecond precision.

**Default:** 6 seconds

### HadoopFSReadRetryTimeout

Number of seconds a read operation waits before failing. Accepts float values for millisecond precision. If you are confident that your file system will fail more quickly, you can improve performance by lowering this value.

**Default:** 180 seconds

### HadoopFSReplication

Number of replicas HDFS makes. This is independent of the replication that Vertica does to provide K-safety. Do not change this setting unless directed otherwise by Vertica support.

**Default:** 3

### HadoopFSRetryWaitInterval

Initial number of seconds to wait before retrying read, write, and metadata operations. Accepts float values for millisecond precision. The retry interval increases exponentially with every retry.

**Default:** 3 seconds

### HadoopFSTokenRefreshFrequency

How often, in seconds, to refresh the Hadoop tokens used to hold Kerberos tickets (see [Token expiration](#)).

**Default:** 0 (refresh when token expires)

### HadoopFSWriteRetryTimeout

Number of seconds a write operation waits before failing. Accepts float values for millisecond precision. If you are confident that your file system will fail more quickly, you can improve performance by lowering this value.

**Default:** 180 seconds

### HadoopImpersonationConfig

Session parameter specifying the delegation token or Hadoop user for HDFS access. See [HadoopImpersonationConfig format](#) for information about the value of this parameter and [Proxy users and delegation tokens](#) for more general context.

### HDFSUseWebHDFS

Boolean, whether URLs in the `hdfs` scheme use WebHDFS instead of LibHDFS++ to access data.

#### Deprecated

This parameter is deprecated because LibHDFS++ is deprecated. In the future, Vertica will use WebHDFS for all `hdfs` URLs.

**Default:** 1 (enabled)

### WebhdfsClientCertConf

mTLS configurations for accessing one or more WebHDFS servers. The value is a JSON string; each member has the following properties:

- `nameservice` : WebHDFS name service
- `authority` : `host` : `port`
- `certName` : name of a certificate defined by [CREATE CERTIFICATE](#)

`nameservice` and `authority` are mutually exclusive.

For example:

```
=> ALTER SESSION SET WebhdfsClientCertConf =
 [{"authority" : "my.authority.com:50070", "certName" : "myCert"},
 {"nameservice" : "prod", "certName" : "prodCert"}];
```

The following table describes the parameters for configuring the HCatalog Connector. See [Using the HCatalog Connector](#) for more information.

#### Note

You can override HCatalog configuration parameters when you create an HCatalog schema with [CREATE HCATALOG SCHEMA](#).

#### EnableHCatImpersonation

Boolean, whether the HCatalog Connector uses (impersonates) the current Vertica user when accessing Hive. If impersonation is enabled, the HCatalog Connector uses the Kerberos credentials of the logged-in Vertica user to access Hive data. Disable impersonation if you are using an authorization service to manage access without also granting users access to the underlying files. For more information, see [Configuring security](#).

**Default:** 1 (enabled)

#### HCatalogConnectorUseHiveServer2

Boolean, whether Vertica internally uses HiveServer2 instead of WebHCat to get metadata from Hive.

**Default:** 1 (enabled)

#### HCatalogConnectorUseLibHDFSPP

Boolean, whether the HCatalog Connector should use the `hdfs` scheme instead of `webhdfs` with the HCatalog Connector.

#### Deprecated

Vertica uses the `hdfs` scheme by default. To use `webhdfs`, set the `HDFSUseWebHDFS` parameter.

**Default:** 1 (enabled)

#### HCatConnectionTimeout

The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer2 (or WebHCat) server before returning a timeout error.

**Default:** 0 (Wait indefinitely)

#### HCatSlowTransferLimit

Lowest transfer speed (in bytes per second) that the HCatalog Connector allows when retrieving data from the HiveServer2 (or WebHCat) server. In some cases, the data transfer rate from the server to Vertica is below this threshold. In such cases, after the number of seconds specified in the `HCatSlowTransferTime` parameter pass, the HCatalog Connector cancels the query and closes the connection.

**Default:** 65536

#### HCatSlowTransferTime

Number of seconds the HCatalog Connector waits before testing whether the data transfer from the server is too slow. See the `HCatSlowTransferLimit` parameter.

**Default:** 60

#### Internationalization parameters

The following table describes internationalization parameters for configuring Vertica.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

#### DefaultIntervalStyle

Sets the default interval style to use. If set to 0 (default), the interval is in PLAIN style (the SQL standard), no interval units on output. If set to 1, the interval is in UNITS on output. This parameter does not take effect until the database is restarted.

**Default:** 0

#### DefaultSessionLocale

Sets the default session startup locale for the database. This parameter does not take effect until the database is restarted.

**Default:** `en_US@collation=binary`

#### EscapeStringWarning

Issues a warning when backslashes are used in a string literal. This can help locate backslashes that are being treated as escape characters so they can be fixed to follow the SQL standard-conforming string syntax instead.

**Default:** 1

### StandardConformingStrings

Determines whether [character string literals](#) treat backslashes () as string literals or escape characters. When set to -1, backslashes are treated as string literals; when set to 0, backslashes are treated as escape characters.

#### Tip

To treat backslashes as escape characters, use the Extended string syntax

```
(E'...');
```

**Default:** -1

### Kafka user-defined session parameters

Set Vertica user-defined session parameters to configure Kafka SSL when not using a scheduler, using [ALTER SESSION SET UDPARAMETER](#). The `kafka_`-prefixed parameters configure SSL authentication for Kafka. For details, see [TLS/SSL encryption with Kafka](#).

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

#### `kafka_SSL_CA`

The contents of the certificate authority certificate. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_SSL_CA='MIIBOQIBAAJBAIOL';
```

**Default:** none

#### `kafka_SSL_Certificate`

The contents of the SSL certificate. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_SSL_Certificate='XrM07O4dV/nJ5g';
```

This parameter is optional when the Kafka server's parameter `ssl.client.auth` is set to `none` or `requested`.

**Default:** none

#### `kafka_SSL_PrivateKey_secret`

The private key used to encrypt the session. Vertica does not log this information. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKey_secret='A60iThKtezaCk7F';
```

This parameter is optional when the Kafka server's parameter `ssl.client.auth` is set to `none` or `requested`.

**Default:** none

#### `kafka_SSL_PrivateKeyPassword_secret`

The password used to create the private key. Vertica does not log this information.

For example:

```
ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKeyPassword_secret='secret';
```

This parameter is optional when the Kafka server's parameter `ssl.client.auth` is set to `none` or `requested`.

**Default:** none

#### `kafka_Enable_SSL`

Enables SSL authentication for Vertica-Kafka integration. For example:

```
=> ALTER SESSION SET UDPARAMETER kafka_Enable_SSL=1;
```

**Default:** 0

#### `MaxSessionUDPParameterSize`

Sets the maximum length of a value in a user-defined session parameter. For example:

```
=> ALTER SESSION SET MaxSessionUDPParameterSize = 2000
```

**Default:** 1000

Related topics

## [User-defined session parameters](#)

### Kerberos parameters

The following parameters let you configure the Vertica principal for Kerberos authentication and specify the location of the Kerberos **keytab** file.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

#### **KerberosEnableKeytabPermissionCheck**

Whether the Vertica server verifies permissions on the keytab file. By default, the Vertica server verifies these permissions.

In a [hybrid Kubernetes cluster](#), set this parameter to **0** so that there is no permissions check. Otherwise, Kerberos authentication fails because the keytab file is stored in a Secret, and the VerticaDB operator cannot verify permissions on a Secret.

**Default** : 1

#### **KerberosHostname**

Instance or host name portion of the Vertica Kerberos principal. For example:

```
vertica/host@EXAMPLE.COM
```

If you omit the optional **KerberosHostname** parameter, Vertica uses the return value from the function `gethostname()`. Assuming each cluster node has a different host name, those nodes will each have a different principal, which you must manage in that node's keytab file.

#### **KerberosKeytabFile**

Location of the **keytab** file that contains credentials for the Vertica Kerberos principal. By default, this file is located in `/etc`. For example:

```
KerberosKeytabFile=/etc/krb5.keytab
```

#### **Note**

- The principal must take the form **KerberosServiceName/KerberosHostName@KerberosRealm**
- The **keytab** file must be readable by the file owner who is running the process (typically the Linux dbadmin user assigned file permissions 0600).

#### **KerberosRealm**

Realm portion of the Vertica Kerberos principal. A realm is the authentication administrative domain and is usually formed in uppercase letters.

For example:

```
vertica/hostEXAMPLE.COM
```

#### **KerberosServiceName**

Service name portion of the Vertica Kerberos principal. By default, this parameter is **vertica**. For example:

```
vertica/host@EXAMPLE.COM
```

**Default:** vertica

#### **KerberosTicketDuration**

Lifetime of the ticket retrieved from performing a kinit. The default is 0 (zero) which disables this parameter.

If you omit setting this parameter, the lifetime is determined by the default Kerberos configuration.

## Machine learning parameters

You use machine learning parameters to configure various aspects of machine learning functionality in Vertica.

#### **MaxModelSizeKB**

Sets the maximum size of models that can be imported. The sum of the size of files specified in the metadata.json file determines the model size. The unit of this parameter is KBytes. The native Vertica model (category=VERTICA\_MODELS) is exempted from this limit. If you can export the model from Vertica, and the model is not altered while outside Vertica, you can import it into Vertica again.

The MaxModelSizeKB parameter can be set only by a superuser and only at the database level. It is visible only to a superuser. Its default value is 4GB, and its valid range is between 1KB and 64GB (inclusive).

Examples:

To set this parameter to 3KB:

```
=> ALTER DATABASE DEFAULT SET MaxModelSizeKB = 3;
```

To set this parameter to 64GB (the maximum allowed):

```
=> ALTER DATABASE DEFAULT SET MaxModelSizeKB = 67108864;
```

To reset this parameter to the default value:

```
=> ALTER DATABASE DEFAULT CLEAR MaxModelSizeKB;
```

**Default:** 4GB

## Memory management parameters

The following table describes parameters for managing Vertica memory usage.

### Caution

Modify these parameters only under guidance from Vertica Support.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### MemoryPollerIntervalSec

Specifies in seconds how often the Vertica memory poller checks whether Vertica memory usage is below the thresholds of several configuration parameters (see below):

- [MemoryPollerMallocBloatThreshold](#)
- [MemoryPollerReportThreshold](#)
- [MemoryPollerTrimThreshold](#)

Important

To disable polling of all thresholds, set this parameter to 0. Doing so effectively disables automatic memory usage [reporting](#) and [trimming](#).

**Default:** 2

### MemoryPollerMallocBloatThreshold

Threshold of [glibc memory bloat](#).

The memory poller calls glibc function `malloc_info()` to obtain the amount of free memory in malloc. It then compares [MemoryPollerMallocBloatThreshold](#) —by default, set to 0.3— with the following expression:

```
free-memory-in-malloc / RSS
```

If this expression evaluates to a value higher than [MemoryPollerMallocBloatThreshold](#), the memory poller calls glibc function `malloc_trim()`. This function reclaims free memory from malloc and returns it to the operating system. Details on calls to `malloc_trim()` are written to system table [MEMORY\\_EVENTS](#).

To disable polling of this threshold, set the parameter to 0.

**Default:** 0.3

### MemoryPollerReportThreshold

Threshold of memory usage that determines whether the Vertica memory poller [writes a report](#).

The memory poller compares [MemoryPollerReportThreshold](#) with the following expression:

```
RSS / available-memory
```

When this expression evaluates to a value higher than [MemoryPollerReportThreshold](#) —by default, set to 0.93, then the memory poller writes a report to [MemoryReport.log](#), in the Vertica working directory. This report includes information about Vertica memory pools, how much memory is consumed by individual queries and session, and so on. The memory poller also logs the report as an event in system table [MEMORY\\_EVENTS](#), where it sets `EVENT_TYPE` to `MEMORY_REPORT`.

To disable polling of this threshold, set the parameter to 0.

**Default:** 0.93

### MemoryPollerTrimThreshold

Threshold for the memory poller to start checking whether to [trim glibc-allocated memory](#).

The memory poller compares [MemoryPollerTrimThreshold](#) —by default, set to 0.83— with the following expression:

```
RSS / available-memory
```

If this expression evaluates to a value higher than `MemoryPollerTrimThreshold`, then the memory poller starts checking the next threshold—set in `MemoryPollerMallocBloatThreshold`—for glibc memory bloat.

To disable polling of this threshold, set the parameter to 0. Doing so also disables polling of `MemoryPollerMallocBloatThreshold`.

**Default:** 0.83

## Monitoring parameters

The following parameters control options for monitoring the Vertica database.

Query the `CONFIGURATION_PARAMETERS` system table to determine what levels (node, session, user, database) are valid for a given parameter.

### EnableDataCollector

Enables the Data Collector, which is the `Workload Analyzer`'s internal diagnostics utility. Affects all sessions on all nodes. To disable, set to 0.

**Default:** 1 (enabled)

### EnableLogRotate

Enables and disables the timed `LogRotate service`.

**Default:** 1 (enabled)

### LogRotateInterval

`Interval literal`, how often the `LogRotate service` runs.

**Default:** 8h (runs every 8 hours)

### LogRotateMaxAge

`Interval literal`, the maximum age of rotated logs ( `.gz` ) to keep. Rotated logs with an age greater than this value are rotated. For details, see `Rotating log files`.

**Default:** 7 days

### LogRotateMaxSize

String, the maximum size of a log ( `.log` ) file. The string has format `integer {K|M|G|T}`, where `K` is kibibytes, `M` is mebibytes, `G` is gibibytes, and `T` is tebibytes. Logs larger than this value are rotated. For details, see `Rotating log files`.

**Default:** 100M

### SnmpTrapDestinationsList

Defines where Vertica sends traps for SNMP. See `Configuring reporting for SNMP`. For example:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'localhost 162 public';
```

**Default:** none

### SnmpTrapsEnabled

Enables event trapping for SNMP. See `Configuring reporting for SNMP`.

**Default:** 0

### SnmpTrapEvents

Defines which events Vertica traps through SNMP. See `Configuring reporting for SNMP`. For example:

```
=> ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';
```

**Default:** Low Disk Space, Read Only File System, Loss of K Safety, Current Fault Tolerance at Critical Level, Too Many ROS Containers, Node State Change, Recovery Failure, Stale Checkpoint, and CRC Mismatch.

### SyslogEnabled

Enables event trapping for syslog. See `Configuring reporting for syslog`.

**Default:** 0 (disabled)

### SyslogEvents

Defines events that generate a syslog entry. See `Configuring reporting for syslog`. For example:

```
=> ALTER DATABASE DEFAULT SET SyslogEvents = 'Low Disk Space, Recovery Failure';
```

**Default:** none

### SyslogFacility

Defines which SyslogFacility Vertica uses. See [Configuring reporting for syslog](#).

**Default:** user

## Numeric precision parameters

The following configuration parameters let you configure numeric precision for numeric data types. For more about using these parameters, see [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#).

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### **AllowNumericOverflow**

Boolean, set to one of the following:

- 1 (true): Allows silent numeric overflow. Vertica does not implicitly extend precision of numeric data types. Vertica ignores the value of NumericSumExtraPrecisionDigits.
- 0 (false): Vertica produces an overflow error, if a result exceeds the precision set by NumericSumExtraPrecisionDigits.

**Default:** 1 (true)

### **NumericSumExtraPrecisionDigits**

An integer between 0 and 20, inclusive. Vertica produces an overflow error if a result exceeds the specified precision. This parameter setting only applies if AllowNumericOverflow is set to 0 (false).

**Default:** 6 (places beyond the DDL-specified precision)

## Profiling parameters

The following table describes the profiling parameters for configuring Vertica. See [Profiling database performance](#) for more information on profiling queries.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### **GlobalEEProfiling**

Enables profiling for query execution runs in all sessions on all nodes.

**Default:** 0

### **GlobalQueryProfiling**

Enables query profiling for all sessions on all nodes.

**Default:** 0

### **GlobalSessionProfiling**

Enables session profiling for all sessions on all nodes.

**Default:** 0

### **SaveDCEPProfileThresholdUS**

Sets in microseconds the query duration threshold for saving profiling information to system tables [QUERY\\_CONSUMPTION](#) and [EXECUTION\\_ENGINE\\_PROFILES](#). You can set this parameter to a maximum value of 2147483647 ( $2^{31} - 1$ , or ~35.79 minutes).

**Default:** 60000000 (60 seconds)

## Projection parameters

The following configuration parameters help you manage projections.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### **AnalyzeRowCountInterval**

Specifies how often Vertica checks the number of projection rows and whether the threshold set by [ARCCommitPercentage](#) has been crossed.

For more information, see [Collecting database statistics](#).

**Default:** 86400 seconds (24 hours)

### **ARCCommitPercentage**

Sets the threshold percentage of difference between the last-recorded aggregate projection row count and current row count for a given table. When the difference exceeds this threshold, Vertica updates the catalog with the current row count.

**Default:** 3 (percent)

### **ContainersPerProjectionLimit**

Specifies how many ROS containers Vertica creates per projection before ROS pushback occurs.

### Caution

Increasing this parameter's value can cause serious degradation of database performance. Vertica strongly recommends that you not modify this parameter without first consulting with Customer Support professionals.

**Default:** 1024

### MaxAutoSegColumns

Specifies the number of columns (0 –1024) to use in an [auto-projection](#)'s hash segmentation clause. Set to 0 to use all columns.

**Default:** 8

### MaxAutoSortColumns

Specifies the number of columns (0 –1024) to use in an [auto-projection](#)'s sort expression. Set to 0 to use all columns.

**Default:** 8

### RebalanceQueryStorageContainers

By default, prior to performing a rebalance, Vertica performs a system table query to compute the size of all projections involved in the rebalance task. This query enables Vertica to optimize the rebalance to most efficiently utilize available disk space. This query can, however, significantly increase the time required to perform the rebalance.

By disabling the system table query, you can reduce the time required to perform the rebalance. If your nodes are low on disk space, disabling the query increases the chance that a node runs out of disk space. In that situation, the rebalance fails.

**Default:** 1 (enable)

### RewriteQueryForLargeDim

If enabled (1), Vertica rewrites a SET USING or DEFAULT USING query during a [REFRESH\\_COLUMNS](#) operation by reversing the inner and outer join between the target and source tables. Doing so can optimize refresh performance in cases where the source data is in a table that is larger than the target table.

Important

Enable this parameter only if the SET USING source data is in a table that is larger than the target table. If the source data is in a table smaller than the target table, then enabling RewriteQueryForLargeDim can adversely affect refresh performance.

**Default:** 0

### SegmentAutoProjection

Determines whether [auto-projections](#) are segmented if the table definition omits a segmentation clause. You can set this parameter at database and session scopes.

**Default:** 1 (create segmented auto projections)

## S3 parameters

Use the following parameters to configure reading from S3 file systems and on-premises storage with S3-compatible APIs. For more information about reading data from S3, see [S3 Object Store](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

## AWSAuth

ID and secret key for authentication. For extra security, do not store credentials in the database; use [ALTER SESSION...SET PARAMETER](#) to set this value for the current session only. If you use a shared credential, you can set it in the database with [ALTER DATABASE...SET PARAMETER](#).

For example:

```
=> ALTER SESSION SET AWSAuth='ID:secret';
```

In AWS, these arguments are named AccessKeyId and SecretAccessKey.

To use admintools [create\\_db](#) or [revive\\_db](#) for Eon Mode on-premises, create a configuration file called [auth\\_params.conf](#) with these settings:

```
AWSAuth = key:secret
AWSEndpoint = IP:port
```

## AWSCAFile

File name of the TLS server certificate bundle to use. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
=> ALTER DATABASE DEFAULT SET AWSCAFile = '/etc/ssl/ca-bundle.pem';
```

**Default:** system-dependent

## AWSCAPath

Path Vertica uses to look up TLS server certificate bundles. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
=> ALTER DATABASE DEFAULT SET AWSCAPath = '/etc/ssl/';
```

**Default:** system-dependent

## AWSEnableHttps

Boolean, specifies whether to use the HTTPS protocol when connecting to S3, can be set only at the database level with [ALTER DATABASE](#). If you choose not to use TLS, this parameter must be set to 0.

**Default :** 1 (enabled)

## AWSEndpoint

Endpoint to use when interpreting S3 URLs, set as follows.

Important

Do not include `http(s)://` for AWS endpoints.

- AWS: `hostname_or_ip : port_number`.
- AWS with a [FIPS-compliant S3 Endpoint](#): `S3_hostname` and enable virtual addressing:

Important

Do not include `http(s)://`

```
AWSEndpoint = s3-fips.dualstack.us-east-1.amazonaws.com
S3EnableVirtualAddressing = 1
```

- On-premises/Pure: IP address of the Pure Storage server. If using admintools `create_db` or `revive_db`, create configuration file `auth_params.conf` and include these settings:

```
awsauth = key:secret
awsendpoint = IP:port
```

- When `AWSEndpoint` is not set, the default behavior is to use virtual-hosted request URLs.

**Default:** `s3.amazonaws.com`

## AWSLogLevel

Log level, one of the following:

- OFF
- FATAL
- ERROR
- WARN
- INFO
- DEBUG
- TRACE

**\*\*Default:\*\***ERROR

## AWSRegion

[AWS region](#) containing the S3 bucket from which to read files. This parameter can only be configured with one region at a time. If you need to access buckets in multiple regions, change the parameter each time you change regions.

If you do not set the correct region, you might experience a delay before queries fail because Vertica retries several times before giving up.

**Default:** us-east-1

## AWSSessionToken

Temporary security token generated by running the `get-session-token` command, which generates temporary credentials you can use to configure multi-factor authentication.

Set this parameter in a user session using [ALTER SESSION](#). You can set this parameter at the database level, but be aware that session tokens are temporary. When the token expires, any attempt to access AWS fails.

#### Note

If you use session tokens at the session level, you must set all parameters at the session level, even if some of them are set at the database level. Use [ALTER SESSION](#) to set session parameters.

### AWSStreamingConnectionPercentage

Controls the number of connections to the communal storage that Vertica uses for streaming reads. In a cloud environment, this setting helps prevent streaming data from communal storage using up all available file handles. It leaves some file handles available for other communal storage operations.

Due to the low latency of on-premises object stores, this option is unnecessary for an Eon Mode database that uses on-premises communal storage. In this case, disable the parameter by setting it to 0.

### S3BucketConfig

A JSON array of objects specifying per-bucket configuration overrides. Each property other than the bucket name has a corresponding configuration parameter (shown in parentheses). If both the database-level parameter and its equivalent in S3BucketConfig are set, the value in S3BucketConfig takes precedence.

Properties:

- **bucket** : Name of the bucket
- **region** (AWSRegion): Name of the region
- **protocol** (AWSEnableHttps): Connection protocol, either **http** or **https**
- **endpoint** (AWSEndpoint): Endpoint URL or IP address
- **enableVirtualAddressing** (S3EnableVirtualAddressing): Whether to rewrite the S3 URL to use a virtual hosted path
- **requesterPays** (S3RequesterPays): Whether requester (instead of bucket owner) pays the cost of accessing data on the bucket
- **serverSideEncryption** (S3ServerSideEncryption): Encryption algorithm if using SSE-S3 or SSE-KMS, one of **AES256**, **aws:kms**, or an empty string
- **sseCustomerAlgorithm** (S3SseCustomerAlgorithm): Encryption algorithm if using SSE-C; must be **AES256**
- **sseCustomerKey** (S3SseCustomerKey): Key if using SSE-C encryption, either 32-character plaintext or 44-character base64-encoded
- **sseKmsKeyId** (S3SseKmsKeyId): Key ID if using SSE-KMS encryption
- **proxy** (S3Proxy): HTTP(S) proxy string

The configuration properties for a given bucket might differ based on its type. For example, the following S3BucketConfig is for an AWS bucket **AWSBucket** and a Pure Storage bucket **PureStorageBucket**. **AWSBucket** doesn't specify an endpoint, so Vertica uses the value of **AWSEndpoint**, which defaults to **s3.amazonaws.com** :

```
ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
[
 {
 "bucket": "AWSBucket",
 "region": "us-east-2",
 "protocol": "https",
 "requesterPays": true
 },
 {
 "bucket": "PureStorageBucket",
 "endpoint": "pure.mycorp.net:1234",
 "protocol": "http",
 "enableVirtualAddressing": false
 }
];
```

### S3BucketCredentials

Contains credentials for accessing an S3 bucket. Each property in S3BucketCredentials has an equivalent parameter (shown in parentheses). When set, S3BucketCredentials takes precedence over both **AWSAuth** and **AWSSessionToken**.

Providing credentials for more than one bucket authenticates to them simultaneously, allowing you to perform cross-endpoint joins, export from one bucket to another, etc.

Properties:

- **bucket** : Name of the bucket
- **accessKey** : Access key for the bucket (the *ID* in AWSAuth)
- **secretAccessKey** : Secret access key for the bucket (the *secret* in AWSAuth)
- **sessionToken** : Session token, only used when S3BucketCredentials is set at the session level (AWSSessionToken)

For example, the following S3BucketCredentials is for an AWS bucket **AWSBucket** and a Pure Storage bucket **PureStorageBucket** and sets all possible properties:

```
ALTER SESSION SET S3BucketCredentials='
[
 {
 "bucket": "AWSBucket",
 "accessKey": "<AK0>",
 "secretAccessKey": "<SAK0>",
 "sessionToken": "1234567890"
 },
 {
 "bucket": "PureStorageBucket",
 "accessKey": "<AK1>",
 "secretAccessKey": "<SAK1>"
 }
];
```

This parameter is only visible to the superuser. Users can set this parameter at the session level with [ALTER SESSION](#).

### S3EnableVirtualAddressing

Boolean, specifies whether to rewrite S3 URLs to use virtual-hosted paths. For example, if you use AWS, the S3 URLs change to **bucketname.s3.amazonaws.com** instead of **s3.amazonaws.com/bucketname**. This configuration setting takes effect only when you have specified a value for [AWSEndpoint](#).

If you set AWSEndpoint to a [FIPS-compliant S3 Endpoint](#), you must enable S3EnableVirtualAddressing in auth\_params.conf:

```
AWSEndpoint = s3-fips.dualstack.us-east-1.amazonaws.com
S3EnableVirtualAddressing = 1
```

The value of this parameter does not affect how you specify S3 paths.

**Default:** 0 (disabled)

#### Note

As of September 30, 2020, AWS requires virtual address paths for newly created buckets.

### S3Proxy

HTTP(S) proxy settings, if needed, a string in the following format:

```
http[s]://[user:password@]host[:port]
```

**Default:** "" (empty string)

### S3RequesterPays

Boolean, specifies whether requester (instead of bucket owner) pays the cost of accessing data on the bucket. When true, the bucket owner is only responsible for paying the cost of storing the data, rather than all costs associated with the bucket; must be set in order to access S3 buckets configured as Requester Pays buckets. By setting this property to true, you are accepting the charges for accessing data. If not specified, the default value is false.

### S3ServerSideEncryption

String, encryption algorithm to use when reading or writing to S3. The value depends on which type of encryption at rest is configured for S3:

- **AES256** : Use for SSE-S3 encryption
- **aws:kms** : Use for SSE-KMS encryption
- Empty string ( "" ): No encryption

SSE-C encryption does not use this parameter. Instead, see S3SseCustomerAlgorithm.

For details on using SSE parameters, see [S3 object store](#).

**Default:** "" (no encryption)

### S3SseCustomerAlgorithm

String, the encryption algorithm to use when reading or writing to S3 using SSE-C encryption. The only supported values are [AES256](#) and "" .

For SSE-S3 and SSE-KMS, instead use S3ServerSideEncryption.

**Default:** "" (no encryption)

### S3SseCustomerKey

If using SSE-C encryption, the client key for S3 access.

### S3SseKmsKeyId

If using SSE-KMS encryption, the key identifier (not the key) to pass to the Key Management Server. Vertica must have permission to use the key, which is managed through KMS.

## SNS parameters

The following parameters configure [Amazon Simple Notification Service \(SNS\) notifiers](#). These parameters can only be set at the database level and some, if unset, fall back to their equivalent [S3 parameters](#).

Notifiers must be disabled and then reenabled for these parameters to take effect:

```
-> ALTER NOTIFIER sns_notifier DISABLE;
-> ALTER NOTIFIER sns_notifier ENABLE;
```

### SNSAuth (falls back to AWSAuth)

ID and secret key for authentication, equivalent to the AccessKeyID and SecretAccessKey in AWS. For example:

```
-> ALTER DATABASE DEFAULT SET SNSAuth='myID.mySecret';
```

**Default:** "" (empty string)

### SNSCAFile (falls back to AWSCAFile)

File name of the TLS server certificate bundle to use. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
-> ALTER DATABASE DEFAULT SET SNSCAFile = '/etc/ssl/ca-bundle.pem';
```

**Default:** "" (empty string)

### SNSCAPath (falls back to AWSCAPath)

Path Vertica uses to look up TLS server certificate bundles. If set, this parameter overrides the Vertica default CA bundle path specified in the [SystemCABundlePath](#) parameter.

```
-> ALTER DATABASE DEFAULT SET SNSCAPath = '/etc/ssl/';
```

**Default:** "" (empty string)

### SNSEnableHttps

Boolean, specifies whether to use the HTTPS protocol when connecting to S3, can be set only at the database level with [ALTER DATABASE](#). If you choose not to use TLS, this parameter must be set to 0.

**Default:** 1 (enabled)

### SNSEndpoint

URL of the SNS API endpoint. If this parameter is set to an empty string and the region is specified (either by SNSRegion or its fallback to AWSRegion), Vertica automatically infers the appropriate endpoint.

If you use FIPS, you must manually specify a [FIPS-compliant endpoint](#).

**Default:** "" (empty string)

### SNSRegion (falls back to AWSRegion)

[AWS region](#) for the SNSEndpoint. This parameter can only be configured with one region at a time.

**Default:** "" (empty string)

## SQS parameters

The following parameters configure access to [Amazon Simple Queue Service \(SQS\)](#) queues. SQS is used with [CREATE DATA LOADER](#) to automatically load data from a queue into Vertica. These parameters can be set at the database or session level and some, if unset, fall back to their equivalent [S3 parameters](#).

### SQSAuth (falls back to AWSAuth)

ID and secret key for authentication, equivalent to the AccessKeyID and SecretAccessKey in AWS. For example:

```
=> ALTER DATABASE DEFAULT SET SQSAuth='myID:mySecret';
```

**Default:** "" (empty string)

### SQSQueueCredentials

Per-queue credentials for accessing SQS queues, a JSON array. When set, these values take precedence over SQSAuth.

Properties:

- **accessKey** : Access key for the queue (the *ID* in AWSAuth)
- **secretAccessKey** : Secret access key for the queue (the *secret* in AWSAuth)
- **sessionToken** : AWS session token, only used when SQSQueueCredentials is set at the session level

The following example sets credentials for two queues:

```
=> ALTER SESSION SET SQSQueueCredentials=[
 { "queue": "queue0", "accessKey": "<AK0>", "secretAccessKey": "<SAK0>", "sessionToken": "1234567890" },
 { "queue": "queue1", "accessKey": "foo", "secretAccessKey": "bar" }];
```

**Default:** "" (empty string)

### SQSSessionToken

Temporary, session-level SQS access token. Set this parameter in a user session using [ALTER SESSION](#).

If you set a session token at the [session level](#), you must also set SQSAuth at the session level, even if it is already set at the [database level](#).

In general, SQSSessionToken should be set only at the session level. While you can set this parameter at the database level, session tokens are ephemeral, so when the database-level token expires, you must set it again either at the session or database level.

## Security parameters

Use these client authentication configuration parameters and general security parameters to configure TLS.

- To configure Vertica for client-server TLS, see [Configuring client-server TLS](#).
- To configure JDBC and ODBC clients for TLS, see [Configuring TLS for JDBC clients](#) and [Configuring TLS for ODBC Clients](#).
- For Kerberos-related parameters, see [Kerberos parameters](#).

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

Database parameters

### DataSSLParams

This parameter has been deprecated. Use the [data\\_channel](#) TLS Configuration instead.

Enables encryption using SSL on the data channel. The value of this parameter is a comma-separated list of the following:

- An SSL certificate (chainable)
- The corresponding SSL private key
- The SSL CA (Certificate Authority) certificate.

You should set **EncryptSpreadComm** before setting this parameter.

In the following example, the SSL Certificate contains two certificates, where the certificate for the non-root CA verifies the certificate for the cluster. This is called an SSL Certificate Chain.

```
=> ALTER DATABASE DEFAULT SET PARAMETER DataSSLParams =
'-----BEGIN CERTIFICATE-----<certificate for Cluster>-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----<certificate for non-root CA>-----END CERTIFICATE-----,
-----BEGIN RSA PRIVATE KEY-----<private key for Cluster>-----END RSA PRIVATE KEY-----,
-----BEGIN CERTIFICATE-----<certificate for public CA>-----END CERTIFICATE-----';
```

### DefaultIdleSessionTimeout

Indicates a default session timeout value for all users where [IDLESESSIONTIMEOUT](#) is not set. For example:

```
=> ALTER DATABASE DEFAULT SET defaultidlesessiontimeout = '300 secs';
```

## DHParams

### Deprecated

This parameter has been deprecated and will be removed in a future release.

String, a Diffie-Hellman group of at least 2048 bits in the form:

```
-----BEGIN DH PARAMETERS-----...-----END DH PARAMETERS-----
```

You can generate your own or use the pre-calculated Modular Exponential (MODP) Diffie-Hellman groups specified in [RFC 3526](#).

Changes to this parameter do not take effect until you restart the database.

**Default:** RFC 3526 2048-bit MODP Group 14:

```
-----BEGIN DH PARAMETERS-----MIIBCakCAQEA//////////
JD9qilWjCNMTGYouA3BzRKQJOCIpnzHQCC76mOxObllFKCHmONAT
d75UZs806QxswKwpt8l8UN0/hNW1tUcJF5IW1dmJefsb0TELppjf
tawv/XLb0Brft7jhr+1qJn6WunyQRfEsf5kkoZIHs5Fs9wgB8uKF
jvwWY2kg2HFXTmkmkWP6j9JM9fg2VdI9yjrZYcYvNWIIVSu57VKQd
wlpZtZww1Tkq8mATxdGwlyhghfDKQXkYuNs474553LBgOhgObJ4O
i7Aeij7XFXfBvTFLJ3ivL9pVYFyg5IUI86pVq5RXSJhiY+gUQFXK
OWoqsqmj//////////wIBAg==-----END DH PARAMETERS-----
```

### DisableInheritedPrivileges

Boolean, whether to disable [privilege inheritance](#) at the database level (enabled by default).

### DoUserSpecificFilteringInSysTables

Boolean, specifies whether a non-superuser can view details of another user:

- 0: Users can view details of other users.
- 1: Users can only view details about themselves.

**Default:** 0

### EnableAllRolesOnLogin

Boolean, specifies whether to automatically enable all roles granted to a user on login:

- 0: Do not automatically enable roles
- 1: Automatically enable roles. With this setting, users do not need to run [SET ROLE](#).

**Default:** 0 (disable)

### EnabledCipherSuites

Specifies which SSL cipher suites to use for secure client-server communication. Changes to this parameter apply only to new connections.

**Default:** Vertica uses the Microsoft Schannel default cipher suites. For more information, see the [Schannel documentation](#).

### EnableConnectCredentialForwarding

When using [CONNECT TO VERTICA](#), whether to use the password of the current user to authenticate to a target database.

**Default:** 0 (disable)

### EnableOAuth2JITCleanup

If enabled, users created by [just-in-time OAuth provisioning](#) are automatically dropped if the user does not log in after the number of days specified by `OAuth2UserExpiredInterval`.

To view provisioned users, see [USERS](#).

**Default:** 0 (disable)

### EncryptSpreadComm

Enables Spread encryption on the control channel, set to one of the following strings:

- `vertica`: Specifies that Vertica generates the Spread encryption key for the database cluster.
- `aws-kms|key-name`, where `key-name` is a named key in the iAWS Key Management Service (KMS). On database restart, Vertica fetches the named key from the KMS instead of generating its own.

If the parameter is empty, Spread communication is unencrypted. In general, you should enable this parameter before modifying other security parameters.

Enabling this parameter requires database restart.

### GlobalHeirUsername

A string that specifies which user inherits objects after their owners are dropped. This setting ensures preservation of data that would otherwise be lost.

Set this parameter to one of the following string values:

- Empty string: Objects of dropped users are removed from the database.
- **username** : Reassigns objects of dropped users to **username** . If **username** does not exist, Vertica creates that user and sets **GlobalHeirUsername** to it.
- **<auto>** : Reassigns objects of dropped LDAP or just-in-time-provisioned users to the **dbadmin** user. The brackets (< and >) are required for this option.

For more information about usage, see [Examples](#) .

**Default:** **<auto>**

### ImportExportTLSMode

When using [CONNECT TO VERTICA](#) to connect to another Vertica cluster for import or export, specifies the degree of stringency for using TLS. Possible values are:

- **PREFER** : Try TLS but fall back to plaintext if TLS fails.
- **REQUIRE** : Use TLS and fail if the server does not support TLS.
- **VERIFY\_CA** : Require TLS (as with REQUIRE), and also validate the other server's certificate using the CA specified by the "server" TLS Configuration's CA certificates (in this case, "ca\_cert" and "ica\_cert"):

```
=> SELECT name, certificate, ca_certificate, mode FROM tls_configurations WHERE name = 'server';
name | certificate | ca_certificate | mode
-----+-----+-----+-----
server | server_cert | ca_cert,ica_cert | VERIFY_CA
(1 row)
```

- **VERIFY\_FULL** : Require TLS and validate the certificate (as with VERIFY\_CA), and also validate the server certificate's hostname.
- **REQUIRE\_FORCE** , **VERIFY\_CA\_FORCE** , and **VERIFY\_FULL\_FORCE** : Same behavior as **REQUIRE** , **VERIFY\_CA** , and **VERIFY\_FULL** , respectively, and cannot be overridden by [CONNECT TO VERTICA](#) .

**Default:** **PREFER**

### InternodeTLSConfig

The [TLS Configuration](#) to use for [internode encryption](#) .

For example:

```
=> ALTER DATABASE DEFAULT SET InternodeTLSConfig = my_tls_config;
```

**Default:** **data\_channel**

### LDAPAuthTLSConfig

The [TLS Configuration](#) to use for [TLS with LDAP authentication](#) .

For example:

```
=> ALTER DATABASE DEFAULT SET LDAPAuthTLSConfig = my_tls_config;
```

**Default:** **ldapauth**

### LDAPLinkTLSConfig

The [TLS Configuration](#) to use for [TLS for the LDAP Link service](#) .

For example:

```
=> ALTER DATABASE DEFAULT SET LDAPLinkTLSConfig = my_tls_config;
```

**Default:** **ldaplink**

### OAuth2JITClient

**Deprecated**

This parameter is deprecated. Use the [OAuth2JITRolesClaimName](#) parameter instead.

The client/application name that contains Vertica roles in the Keycloak identity provider. The Vertica roles under [resource\\_access.OAuth2JITClient.roles](#) are automatically [granted](#) to and set as [default\\_roles](#) for users created by just-in-time provisioning. Roles that do not exist in Vertica are ignored.

For details, see [Just-in-time user provisioning](#).

**Default :** [vertica](#)

### OAuth2JITRolesClaimName

Specifies an IdP client with one or more roles that correspond to a Vertica database role. During just-in-time user provisioning, each client role that matches an existing Vertica role is automatically assigned to the user. Roles that do not exist in Vertica are ignored.

For authentication records that use JWT validation, Vertica retrieves the client roles from the access token.

To retrieve client roles for authentication records that use IdP validation, Vertica sends a request to either the [introspect\\_url](#) or the [userinfo\\_url](#) set in the authentication record. This parameter requires the full path to the roles claim in that request. For example, the full path to the roles claim in a Keycloak request uses the following format:

[resource\\_access.clientName.roles](#)

For details, see [Just-in-time user provisioning](#).

**Default :** [resource\\_access.vertica.roles](#)

### OAuth2JITForbiddenRoles

Vertica database roles that you do not want Vertica to automatically assign to users during [just-in-time provisioning](#). This parameter accepts one or more roles as a comma-separated list.

### OAuth2JITGroupsClaimName

The name of the IdP group whose name or role mappings correspond to Vertica database roles. During [just-in-time user provisioning](#), each group name or group role mapping that matches an existing Vertica role is automatically assigned to the user. Roles that do not exist in Vertica are ignored.

For authentication records that use JWT validation, Vertica retrieves the JIT-provisioned user's groups from the access token.

To retrieve the JIT-provisioned user's groups for authentication records that use IdP validation, Vertica sends a request to either the [introspect\\_url](#) or the [userinfo\\_url](#) set in the authentication record.

**Default :** [groups](#)

### OAuth2UserExpiredInterval

If [EnableOAuth2JITCleanup](#) is enabled, users created by just-in-time OAuth provisioning are automatically dropped after not logging in for the number of days specified by [OAuth2UserExpiredInterval](#). The number of days the user has not logged in is calculated relative to the [LAST\\_LOGIN\\_TIME](#) column in the [USERS](#) system table.

#### Note

The [LAST\\_LOGIN\\_TIME](#) as recorded by the [USERS](#) system table is not persistent; if the database is restarted, the [LAST\\_LOGIN\\_TIME](#) for users created by just-in-time user provisioning is set to the database start time (this appears as an empty value in [LAST\\_LOGIN\\_TIME](#)).

You can view the database start time by querying the [DATABASES](#) system table:

```
EX SELECT database_name, start_time FROM databases;
database_name | start_time

VMart | 2023-02-06 14:26:50.630054-05
(1 row)
```

**Default :** 14

### PasswordLockTimeUnit

The time units for which an [account is locked](#) by [PASSWORD\\_LOCK\\_TIME](#) after [FAILED\\_LOGIN\\_ATTEMPTS](#), one of the following:

- 'd': days (default)

- 'h' : hours
- 'm' : minutes
- 's' : seconds

For example, to configure the [default profile](#) to lock user accounts for 30 minutes after three unsuccessful login attempts:

```
=> ALTER DATABASE DEFAULT SET PasswordLockTimeUnit = 'm'
=> ALTER PROFILE DEFAULT LIMIT PASSWORD_LOCK_TIME 30;
```

### RequireFIPS

Boolean, specifies whether the FIPS mode is enabled:

- 0 (disable)
- 1: (enable)

On startup, Vertica automatically sets this parameter from the contents of the file `crypto.fips_enabled`. You cannot modify this parameter.

For details, see [FIPS compliance for the Vertica server](#).

**Default:** 0

### SecurityAlgorithm

Sets the algorithm for the function that hash authentication uses, one of the following:

- SHA512
- MD5

For example:

```
=> ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'SHA512';
```

**Default:** SHA512

### ServerTLSConfig

The [TLS Configuration](#) to use for [client-server TLS](#).

For example:

```
=> ALTER DATABASE DEFAULT SET ServerTLSConfig = my_tls_config;
```

**Default:** server

### SystemCABundlePath

The absolute path to a certificate bundle of trusted CAs. This CA bundle is used when establishing TLS connections to external services such as AWS or Azure through their respective SDKs and libcurl. The CA bundle file must be in the same location on all nodes.

If this parameter is empty, Vertica searches the "standard" paths for the CA bundles, which differs between distributions:

- Red Hat-based: `/etc/pki/tls/certs/ca-bundle.crt`
- Debian-based: `/etc/ssl/certs/ca-certificates.crt`
- SUSE: `/var/lib/ca-certificates/ca-bundle.pem`

**Example :**

```
=> ALTER DATABASE DEFAULT SET SystemCABundlePath = 'path/to/ca_bundle.pem';
```

**Default:** Empty

TLS parameters

To set your Vertica database's TLSMode, private key, server certificate, and CA certificate(s), see [TLS configurations](#). In versions prior to 11.0.0, these parameters were known as EnableSSL, SSLPrivateKey, SSLCertificate, and SSLCA, respectively.

Examples

Set the database parameter `GlobalHeirUsername` :

```

=> \du
 List of users
User name | Is Superuser
-----+-----
Joe | f
SuzyQ | f
dbadmin | t
(3 rows)

=> ALTER DATABASE DEFAULT SET PARAMETER GlobalHeirUsername='SuzyQ';
ALTER DATABASE
=> \c - Joe
You are now connected as user "Joe".
=> CREATE TABLE t1 (a int);
CREATE TABLE

=> \c
You are now connected as user "dbadmin".
=> \dt t1
 List of tables
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | t1 | table | Joe |
(1 row)

=> DROP USER Joe;
NOTICE 4927: The Table t1 depends on User Joe
ROLLBACK 3128: DROP failed due to dependencies
DETAIL: Cannot drop User Joe because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too
=> DROP USER Joe CASCADE;
DROP USER
=> \dt t1
 List of tables
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | t1 | table | SuzyQ |
(1 row)

```

## Stored procedure parameters

The following parameters configure the behavior of [stored procedures](#) and [triggers](#).

### **EnableNestedStoredProcedures**

Boolean, whether to enable [nested stored procedures](#).

**Default:** 0

### **EnableStoredProcedureScheduler**

Boolean, whether to enable the scheduler. For details, see [Scheduled execution](#).

**Default:** 1

### **PLvSQLCoerceNull**

Boolean, whether to allow NULL-to-false type coercion to improve compatibility with PLpgSQL. For details, see [PL/pgSQL to PL/vSQL migration guide](#).

**Default:** 0

## Text search parameters

You can configure Vertica for text search using the following parameter.

### **TextIndexMaxTokenLength**

Controls the maximum size of a token in a text index.

For example:

```
ALTER DATABASE database_name SET PARAMETER TextIndexMaxTokenLength=760;
```

If the parameter is set to a value greater than 65000 characters, then the tokenizer truncates the token at 65000 characters.

### Caution

Avoid setting this parameter near its maximum value, 65000. Doing so can result in a significant decrease in performance. For optimal performance, set this parameter to the maximum token value of your tokenizer.

**Default:** 128 (characters)

## Tuple mover parameters

These parameters control how the [Tuple Mover](#) operates.

Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

### ActivePartitionCount

Sets the number of [active partitions](#). The active partitions are those most recently created. For example:

```
=> ALTER DATABASE DEFAULT SET ActivePartitionCount = 2;
```

For information about how the Tuple Mover treats active and inactive partitions during a mergeout operation, see [Partition mergeout](#).

**Default:** 1

### CancelTTimeout

When partition, copy table, and rebalance operations encounter a conflict with an internal Tuple Mover job, those operations attempt to cancel the conflicting Tuple Mover job. This parameter specifies the amount of time, in seconds, that the blocked operation waits for the Tuple Mover cancellation to take effect. If the operation is unable to cancel the Tuple Mover job within limit specified by this parameter, the operation displays an error and rolls back.

**Default:** 300

### EnableTMonRecoveringNode

Boolean, specifies whether Tuple Mover performs [mergeout](#) activities on nodes with a [node state](#) of RECOVERING. Enabling Tuple Mover reduces the number of ROS containers generated during recovery. Having fewer than 1024 ROS containers per projection allows Vertica to maintain optimal recovery performance.

**Default:** 1 (enabled)

### MaxMrgOutROSSizeMB

Specifies in MB the maximum size of ROS containers that are candidates for [mergeout](#) operations. The Tuple Mover avoids merging ROS containers that are larger than this setting.

### Note

After a [rebalance operation](#), Tuple Mover groups ROS containers in batches that are smaller than MaxMrgOutROSSizeMB. ROS containers that are larger than MaxMrgOutROSSizeMB are merged individually

**Default:** -1 (no maximum limit)

### MergeOutInterval

Specifies in seconds how frequently the Tuple Mover checks the [mergeout request queue](#) for pending requests:

1. If the queue contains mergeout requests, the Tuple Mover does nothing and goes back to sleep.
2. If the queue is empty, the Tuple Mover:
  - Processes pending storage location move requests.
  - Checks for new unqueued purge requests and adds them to the queue.It then goes back to sleep.

**Default:** 600

### PurgeMergeoutPercent

Specifies as a percentage the threshold of deleted records in a ROS container that invokes an automatic [mergeout](#) operation, to purge those records. Vertica only counts the number of 'aged-out' delete vectors—that is, delete vectors that are as 'old' or older than the ancient history

mark (AHM) epoch.

This threshold applies to all ROS containers for non-partitioned tables. It also applies to ROS containers of all inactive partitions. In both cases, aged-out delete vectors are permanently purged from the ROS container.

#### Note

This configuration parameter only applies to automatic mergeout operations. It does not apply to manual mergeout operations that are invoked by calling meta-functions [DO\\_TM\\_TASK\('mergeout'\)](#) and [PURGE](#).

**Default:** 20 (percent)

## File systems and object stores

Vertica supports access to several file systems and object stores in addition to the Linux file system. The reference pages in this section provide information on URI syntax, configuration parameters, and authentication.

Vertica accesses the file systems in this section in one of two ways:

- If user-provided credentials are present, Vertica uses them to access the storage. Note that on HDFS, user credentials are always present because Vertica accesses HDFS using the Vertica user identity.
- If user-provided credentials are not present, or if the [UseServerIdentityOverUserIdentity](#) configuration parameter is set, Vertica checks for a configured USER storage location. When access is managed through USER storage locations, Vertica uses the server credential to access the file system. For more information about USER storage locations, see [CREATE LOCATION](#).

Not all file systems are supported in all contexts. See the documentation of specific features for the file systems those features support.

In this section

- [Azure Blob Storage object store](#)
- [Google Cloud Storage \(GCS\) object store](#)
- [HDFS file system](#)
- [S3 object store](#)

### Azure Blob Storage object store

Azure has several interfaces for accessing data. Vertica reads and always writes Block Blobs in Azure Storage. Vertica can read external data created using ADLS Gen2, and data that Vertica exports can be read using ADLS Gen2.

URI format

One of the following:

- `azb://account / container / path`
- `azb://[account @] host [: port ] / container / path`

In the first version, a URI like 'azb://myaccount/mycontainer/path' treats the first token after the '/' as the account name. In the second version, you can specify account and must specify host explicitly.

The following rules apply to the second form:

- If *account* is not specified, the first label of the host is used. For example, if the URI is 'azb://myaccount.blob.core.windows.net/mycontainer/my/object', then 'myaccount' is used for *account*.
- If *account* is not specified and *host* has a single label and no port, the endpoint is *host*.blob.core.windows.net. Otherwise, the endpoint is the host and port specified in the URI.

The protocol (HTTP or HTTPS) is specified in the `AzureStorageEndpointConfig` configuration parameter.

Authentication

If you are using Azure managed identities, no further configuration in Vertica is needed. If your Azure storage uses multiple managed identities, you must tag the one to be used. Vertica looks for an Azure tag with a key of `VerticaManagedIdentityClientId`, the value of which must be the `client_id` attribute of the managed identity to be used. If you update the Azure tag, call [AZURE\\_TOKEN\\_CACHE\\_CLEAR](#).

If you are not using managed identities, use the `AzureStorageCredentials` configuration parameter to provide credentials to Azure. If loading data, you can set the parameter at the session level. If using Eon Mode communal storage on Azure, you must set this configuration parameter at the database level.

In Azure you must also grant access to the containers for the identities used from Vertica.

### Configuration parameters

The following database configuration parameters apply to the Azure blob file system. You can set parameters at different levels with the appropriate ALTER statement, such as [ALTER SESSION...SET PARAMETER](#). Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

### AzureStorageCredentials

Collection of JSON objects, each of which specifies connection credentials for one endpoint. This parameter takes precedence over Azure managed identities.

The collection must contain at least one object and may contain more. Each object must specify at least one of `accountName` or `blobEndpoint`, and at least one of `accountKey` or `sharedAccessSignature`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `accountKey`: Access key for the account or endpoint.
- `sharedAccessSignature`: Access token for finer-grained access control, if being used by the Azure endpoint.

### AzureStorageEndpointConfig

Collection of JSON objects, each of which specifies configuration elements for one endpoint. Each object must specify at least one of `accountName` or `blobEndpoint`.

- `accountName`: If not specified, uses the label of `blobEndpoint`.
- `blobEndpoint`: Host name with optional port (`host:port`). If not specified, uses `account.blob.core.windows.net`.
- `protocol`: HTTPS (default) or HTTP.
- `isMultiAccountEndpoint`: true if the endpoint supports multiple accounts, false otherwise (default is false). To use multiple-account access, you must include the account name in the URI. If a URI path contains an account, this value is assumed to be true unless explicitly set to false.

### Examples

The following examples use these values for the configuration parameters. `AzureStorageCredentials` contains sensitive information and is set at the session level in this example.

```
=> ALTER SESSION SET AzureStorageCredentials =
 [{"accountName": "myaccount", "accountKey": "REAL_KEY"},
 {"accountName": "myaccount", "blobEndpoint": "localhost:8080", "accountKey": "TEST_KEY"}];

=> ALTER DATABASE default SET AzureStorageEndpointConfig =
 [{"accountName": "myaccount", "blobEndpoint": "localhost:8080", "protocol": "http"}];
```

The following example creates an external table using data from Azure. The URI specifies an account name of "myaccount".

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
 AS COPY FROM 'azb://myaccount/mycontainer/my/object/*';
```

Vertica uses `AzureStorageEndpointConfig` and the account name to produce the following location for the files:

```
https://myaccount.blob.core.windows.net/mycontainer/my/object/*
```

Data is accessed using the `REAL_KEY` credential.

If the URI in the COPY statement is instead `azb://myaccount.blob.core.windows.net/mycontainer/my/object`, then the resulting location is `https://myaccount.blob.core.windows.net/mycontainer/my/object`, again using the `REAL_KEY` credential.

However, if the URI in the COPY statement is `azb://myaccount@localhost:8080/mycontainer/my/object`, then the host and port specify a different endpoint: `http://localhost:8080/myaccount/mycontainer/my/object`. This endpoint is configured to use a different credential, `TEST_KEY`.

### Google Cloud Storage (GCS) object store

File system using the Google Cloud Storage platform.

URI format

```
gs://bucket/path
```

## Authentication

To access data in Google Cloud Storage (GCS) you must first do the following tasks:

- Create a default project, obtain a developer key, and enable S3 interoperability mode as described in [the GCS documentation](#).
- Set the GCSEAuth configuration parameter as in the following example.

```
=> ALTER SESSION SET GCSEAuth='id:secret';
```

## Configuration parameters

The following database configuration parameters apply to the GCS file system. You can set parameters at different levels with the appropriate ALTER statement, such as [ALTER SESSION...SET PARAMETER](#). Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter. For information about all parameters related to GCS, see [Google Cloud Storage parameters](#).

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

### GCSEAuth

An ID and secret key to authenticate to GCS. For extra security, do not store credentials in the database; instead, use [ALTER SESSION...SET PARAMETER](#) to set this value for the current session only.

### GCSEnableHttps

Boolean, whether to use the HTTPS protocol when connecting to GCS, can be set only at the database level with [ALTER DATABASE...SET PARAMETER](#).

**Default:** 1 (enabled)

### GCS Endpoint

The connection endpoint address.

**Default:** [storage.googleapis.com](https://storage.googleapis.com)

## Examples

The following example loads data from GCS:

```
=> ALTER SESSION SET GCSEAuth='my_id:my_secret_key';
=> COPY t FROM 'gs://DataLake/clicks.parquet' PARQUET;
```

## HDFS file system

HDFS is the Hadoop Distributed File System. You can use the [webhdfs](#) and [swebhdfs](#) schemes to access data through the WebHDFS service. Vertica also supports the [hdfs](#) scheme, which by default uses WebHDFS. To have [hdfs](#) URIs use the deprecated LibHDFS++ package, set the [HDFSUseWebHDFS](#) configuration parameter to 0 (disabled).

If you specify a [webhdfs](#) URI but the Hadoop HTTP policy ( [dfs.http.policy](#) ) is set to HTTPS\_ONLY, Vertica automatically uses [swebhdfs](#) instead.

If you use LibHDFS++, the WebHDFS service must still be available because Vertica falls back to WebHDFS for operations not supported by LibHDFS++.

### Deprecated

Support for LibHDFS++ is deprecated. In the future, HDFSUseWebHDFS will be enabled in all cases and [hdfs](#) URIs will be equivalent to [webhdfs](#) URIs.

## URI format

URIs in the [webhdfs](#), [swebhdfs](#), and [hdfs](#) schemes all have two formats, depending on whether you specify a name service or the host and port of a name node:

- `[[s]web]hdfs://[ nameservice ]/ path`
- `[[s]web]hdfs:// namenode-host:port / path`

Characters may be URL-encoded (%NN where NN is a two-digit hexadecimal number) but are not required to be, except that the '%' character must be encoded.

To use the default name service specified in the HDFS configuration files, omit `nameservice`. Use this shorthand only for reading external data, not for creating a storage location.

Always specify a name service or host explicitly when using Vertica with more than one HDFS cluster. The name service or host name must be globally unique. Using `[web]hdfs://` could produce unexpected results because Vertica uses the first value of `fs.defaultFS` that it finds.

## Authentication

Vertica can use Kerberos authentication with Cloudera or Hortonworks HDFS clusters. See [Accessing kerberized HDFS data](#).

For loading and exporting data, Vertica can access HDFS clusters protected by mTLS through the `swebhdfs` scheme. You must create a certificate and key and set the `WebhdfsClientCertConf` configuration parameter.

You can use `CREATE KEY` and `CREATE CERTIFICATE` to create temporary, session-scoped values if you specify the `TEMPORARY` keyword. Temporary keys and certificates are stored in memory, not on disk.

The `WebhdfsClientCertConf` configuration parameter holds client credentials for one or more HDFS clusters. The value is a JSON string listing name services or authorities and their corresponding keys. You can set the configuration parameter at the session or database level. Setting the parameter at the database level has the following additional requirements:

- The `UseServerIdentityOverUserIdentity` configuration parameter must be set to 1 (true).
- The user must be `dbadmin` or must have access to the user storage location on HDFS.

The following example shows how to use mTLS. The key and certificate values themselves are not shown, just the beginning and end markers:

```
=> CREATE TEMPORARY KEY client_key TYPE 'RSA'
 AS '-----BEGIN PRIVATE KEY-----.....-----END PRIVATE KEY-----';

-> CREATE TEMPORARY CERTIFICATE client_cert
 AS '-----BEGIN CERTIFICATE-----.....-----END CERTIFICATE-----' key client_key;

=> ALTER SESSION SET WebhdfsClientCertConf =
 '[{"authority": "my.hdfs.namenode1:50088", "certName": "client_cert"}]';

=> COPY people FROM 'swebhdfs://my.hdfs.namenode1:50088/path/to/file/1.txt';
Rows Loaded

1
(1 row)
```

To configure access to more than one HDFS cluster, define the keys and certificates and then include one object per cluster in the value of `WebhdfsClientCertConf`:

```
=> ALTER SESSION SET WebhdfsClientCertConf =
 '[{"authority": "my.authority.com:50070", "certName": "myCert"},
 {"nameservice": "prod", "certName": "prodCert"}]';
```

## Configuration parameters

The following database configuration parameters apply to the HDFS file system. You can set parameters at different levels with the appropriate `ALTER` statement, such as `ALTER SESSION...SET PARAMETER`. Query the `CONFIGURATION_PARAMETERS` system table to determine what levels (node, session, user, database) are valid for a given parameter. For information about all parameters related to Hadoop, see [Hadoop parameters](#).

### EnableHDFSBlockInfoCache

Boolean, whether to distribute block location metadata collected during planning on the initiator to all database nodes for execution, reducing name node contention. Disabled by default.

### HadoopConfDir

Directory path containing the XML configuration files copied from Hadoop. The same path must be valid on every Vertica node. The files are accessed by the Linux user under which the Vertica server process runs.

### HadoopImpersonationConfig

Session parameter specifying the delegation token or Hadoop user for HDFS access. See [HadoopImpersonationConfig format](#) for information about the value of this parameter and [Proxy users and delegation tokens](#) for more general context.

### HDFSUseWebHDFS

Boolean. If true (the default), URIs in the `hdfs` scheme are treated as if they were in the `webhdfs` scheme. If false, Vertica uses LibHDFS++ where possible, though some operations can still use WebHDFS if not supported by LibHDFS++.

## WebhdfsClientCertConf

mTLS configurations for accessing one or more WebHDFS servers, a JSON string. Each object must specify either a `nameservice` or `authority` field and a `certName` field. See [Authentication](#).

### Configuration files

The path specified in `HadoopConfDir` must include a directory containing the files listed in the following table. Vertica reads these files at database start time. If you do not set a value, Vertica looks for the files in `/etc/hadoop/conf`.

If a property is not defined, Vertica uses the defaults shown in the table. If no default is specified for a property, the configuration files must specify a value.

File	Properties	Default
core-site.xml	<code>fs.defaultFS</code>	none
	(for doAs users:) <code>hadoop.proxyuser.<i>username</i>.users</code>	none
	(for doAs users:) <code>hadoop.proxyuser.<i>username</i>.hosts</code>	none
hdfs-site.xml	<code>dfs.client.failover.max.attempts</code>	15
	<code>dfs.client.failover.sleep.base.millis</code>	500
	<code>dfs.client.failover.sleep.max.millis</code>	15000
	(For HA NN:) <code>dfs.nameservices</code>	none
	(WebHDFS:) <code>dfs.namenode.http-address</code> or <code>dfs.namenode.https-address</code>	none
	(WebHDFS:) <code>dfs.datanode.http.address</code> or <code>dfs.datanode.https.address</code>	none
	(WebHDFS:) <code>dfs.http.policy</code>	HTTP_ONLY

If using High Availability (HA) Name Nodes, the individual name nodes must also be defined in `hdfs-site.xml`.

#### Note

If you are using Eon Mode with communal storage on HDFS, then if you set `dfs.encrypt.data.transfer` you must use the `swebhdfs` scheme for communal storage.

To verify that Vertica can find configuration files in `HadoopConfDir`, use the [VERIFY\\_HADOOP\\_CONF\\_DIR](#) function.

To test access through the `hdfs` scheme, use the [HDFS\\_CLUSTER\\_CONFIG\\_CHECK](#) function.

For more information about testing your configuration, see [Verifying HDFS configuration](#).

To reread the configuration files, use the [CLEAR\\_HDFS\\_CACHES](#) function.

### Name nodes and name services

You can access HDFS data using the default name node by not specifying a name node or name service:

```
=> COPY users FROM 'webhdfs:///data/users.csv';
```

Vertica uses the `fs.defaultFS` Hadoop configuration parameter to find the name node. (It then uses that name node to locate the data.) You can instead specify a host and port explicitly using the following format:

```
webhdfs://nn-host:nn-port/
```

The specified host is the name node, not an individual data node. If you are using High Availability (HA) Name Nodes you should not use an explicit host because high availability is provided through name services instead.

If the HDFS cluster uses High Availability Name Nodes or defines name services, use the name service instead of the host and port, in the format `webhdfs://nameservice/`. The name service you specify must be defined in `hdfs-site.xml`.

The following example shows how you can use a name service, `hadoopNS`:

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
AS COPY FROM 'webhdfs://hadoopNS/data/users.csv';
```

If you are using Vertica to access data from more than one HDFS cluster, always use explicit name services or hosts in the URL. Using the `///` shorthand could produce unexpected results because Vertica uses the first value of `fs.defaultFS` that it finds. To access multiple HDFS clusters, you must use host and service names that are globally unique. See [Configuring HDFS access](#) for more information.

## S3 object store

File systems using the S3 protocol, including AWS, Pure Storage, and MinIO.

URI format

```
s3://bucket/path
```

For AWS, specify the region using the `AWSRegion` configuration parameter, not the URI. If the region is incorrect, you might experience a delay before the load fails because Vertica retries several times before giving up. The default region is `us-east-1`.

Authentication

For AWS:

- To access S3 you must create an [IAM role](#) and grant that role permission to access your S3 resources.
- By default, bucket access is restricted to the communal storage bucket. Use an [AWS access key](#) to load data from non-communal storage buckets.
- Either set the `AWSAuth` configuration parameter to provide credentials or create a USER storage location for the S3 path (see [CREATE LOCATION](#)) and grant users access.
- You can use AWS STS temporary session tokens to load data. Because they are session tokens, do not use them for access to storage locations.
- You can configure S3 buckets individually with the per-bucket parameters `S3BucketConfig` and `S3BucketCredentials`. For details, see [Per-bucket S3 configurations](#).

Configuration parameters

The following database configuration parameters apply to the S3 file system. You can set parameters at different levels with the appropriate ALTER statement, such as [ALTER SESSION...SET PARAMETER](#). Query the [CONFIGURATION\\_PARAMETERS](#) system table to determine what levels (node, session, user, database) are valid for a given parameter.

You can configure individual buckets using the `S3BucketConfig` and `S3BucketCredentials` parameters instead of the global parameters.

For external tables using highly partitioned data in an object store, see the [ObjectStoreGlobStrategy](#) configuration parameter and [Partitions on Object Stores](#).

The following descriptions are summaries. For details about all parameters specific to S3, see [S3 parameters](#).

### AWSAuth

An ID and secret key for authentication. AWS calls these `AccessKeyID` and `SecretAccessKey`. For extra security, do not store credentials in the database; use [ALTER SESSION...SET PARAMETER](#) to set this value for the current session only.

### AWSCAFile

The file name of the TLS server certificate bundle to use. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server.

### AWSCAPath

The path Vertica uses to look up TLS server certificates. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server.

### AWSEnableHttps

Boolean, whether to use the HTTPS protocol when connecting to S3. Can be set only at the database level. You can set the protocol for individual buckets using `S3BucketConfig`.

**Default:** 1 (enabled)

### AWSEndpoint

String, the endpoint host for all S3 URLs, set as follows:

- AWS: `hostname_or_IP:port`. Do not include the scheme (`http(s)`).
- AWS with a FIPS-compliant S3 Endpoint: Hostname of a [FIPS-compliant S3 endpoint](#). You must also enable `S3EnableVirtualAddressing`.
- On-premises/Pure: IP address of the Pure Storage server.

If not set, Vertica uses virtual-hosted request URLs.

**Default:** 's3.amazonaws.com'

### **AWSLogLevel**

The log level, one of: OFF, FATAL, ERROR, WARN, INFO, DEBUG, or TRACE.

**Default:** ERROR

### **AWSRegion**

The AWS region containing the S3 bucket from which to read files. This parameter can only be configured with one region at a time. Failure to set the correct region can lead to a delay before queries fail.

**Default:** 'us-east-1'

### **AWSSessionToken**

A temporary security token generated by running the [get-session-token](#) command, used to configure multi-factor authentication.

#### **Note**

If you use session tokens at the session level, you must set all parameters at the session level, even if some of them are set at the database level.

### **AWSStreamingConnectionPercentage**

In Eon Mode, the number of connections to the communal storage to use for streaming reads. In a cloud environment, this setting helps prevent streaming data from using up all available file handles. This setting is unnecessary when using on-premises object stores because of their lower latency.

### **S3BucketConfig**

A JSON array of objects specifying per-bucket configuration overrides. Each property other than the bucket name has a corresponding configuration parameter (shown in parentheses). If both the database-level parameter and its equivalent in S3BucketConfig are set, the value in S3BucketConfig takes precedence.

Properties:

- **bucket** : Bucket name
- **region** (AWSRegion)
- **protocol** (AWSEnableHttp): Connection protocol, one of [http](#) or [https](#)
- **endpoint** (AWSEndpoint)
- **enableVirtualAddressing** (S3BucketCredentials): Boolean, whether to rewrite the S3 URL to use a virtual hosted path
- **requesterPays** (S3RequesterPays)
- **serverSideEncryption** (S3ServerSideEncryption)
- **sseCustomerAlgorithm** (S3SseCustomerAlgorithm)
- **sseCustomerKey** (S3SseCustomerKey)
- **sseKmsKeyId** (S3SseKmsKeyId)
- **proxy** (S3Proxy)

### **S3BucketCredentials**

A JSON object specifying per-bucket credentials. Each property other than the bucket name has a corresponding configuration parameter. If both the database-level parameter and its equivalent in S3BucketCredentials are set, the value in S3BucketCredentials takes precedence.

Properties:

- **bucket** : Bucket name
- **accessKey** : Access key for the bucket (the *ID* in AWSAuth)
- **secretAccessKey** : Secret access key for the bucket (the *secret* in AWSAuth)
- **sessionToken** : Session token, only used when S3BucketCredentials is set at the session level (AWSSessionToken)

This parameter is only visible to superusers. Users can set this parameter at the session level with [ALTER SESSION](#).

### **S3EnableVirtualAddressing**

Boolean, whether to rewrite S3 URLs to use virtual-hosted paths (disabled by default). This configuration setting takes effect only when you have specified a value for AWSEndpoint.

If you set AWSEndpoint to a [FIPS-compliant S3 endpoint](#), you must enable S3EnableVirtualAddressing. The value of this parameter does not affect how you specify S3 paths.

### S3Proxy

HTTP(S) proxy settings, if needed, a string in the following format: [http\[s\]://\[user:password@\]host\[:port\]](http[s]://[user:password@]host[:port]) .

### S3RequesterPays

Boolean, whether requester (instead of bucket owner) pays the cost of accessing data on the bucket.

### S3ServerSideEncryption

String, encryption algorithm to use when reading or writing to S3. Supported values are [AES256](#) (for SSE-S3), [aws:kms](#) (for SSE-KMS), and an empty string (for no encryption). See [Server-Side Encryption](#) .

**Default:** "" (no encryption)

### S3SseCustomerAlgorithm

String, the encryption algorithm to use when reading or writing to S3 using SSE-C encryption. The only supported values are [AES256](#) and "" . For SSE-S3 and SSE-KMS, instead use S3ServerSideEncryption.

**Default:** "" (no encryption)

### S3SseCustomerKey

If using SSE-C encryption, the client key for S3 access.

### S3SseKmsKeyId

If using SSE-KMS encryption, the key identifier (not the key) to pass to the Key Management Service. Vertica must have permission to use the key, which is managed through KMS.

### Write performance

By default, Vertica performs writes using a single thread, but a single write usually includes multiple files or parts of files. For writes to S3, you can use a larger thread pool to perform writes in parallel. This thread pool is used for all file writes to S3, including file exports and writes to communal storage.

The size of the thread pool is controlled by the [ObjStoreUploadParallelism](#) configuration parameter. Each node has a single thread pool used for all file writes. In general, one or two threads per concurrent writer produces good results.

### Server-side encryption

By default, Vertica reads and writes S3 data that is not encrypted. If the S3 bucket uses server-side encryption (SSE), you can configure Vertica to access it. S3 supports three types of server-side encryption: SSE-S3, SSE-KMS, and SSE-C.

Vertica must also have read or write permissions (depending on the operation) on the bucket.

### SSE-S3

With SSE-S3, the S3 service manages encryption keys. Reads do not require additional configuration. To write to S3, the client (Vertica, in this case) must specify only the encryption algorithm.

If the S3 bucket is configured with the default encryption settings, Vertica can read and write data to them with no further changes. If the bucket does not use the default encryption settings, set the S3ServerSideEncryption configuration parameter or the [serverSideEncryption](#) field in S3BucketConfig to [AES256](#) .

### SSE-KMS

With SSE-KMS, encryption keys are managed by the Key Management Service (KMS). The client must supply a KMS key identifier (not the actual key) when writing data. For all operations, the client must have permission to use the KMS key. These permissions are managed in KMS, not in Vertica.

To use SSE-KMS:

- Set the S3ServerSideEncryption configuration parameter or the [serverSideEncryption](#) field in S3BucketConfig to [aws:kms](#) .
- Set the S3SseKmsKeyId configuration parameter or the [sseKmsKeyId](#) field in S3BucketConfig to the key ID.

### SSE-C

With SSE-C, the client manages encryption keys and provides them to S3 for each operation.

To use SSE-C:

- Set the S3SseCustomerAlgorithm configuration parameter or the [sseCustomerAlgorithm](#) field in S3BucketConfig to [AES256](#) .
- Set the S3SseCustomerKey configuration parameter or the [sseCustomerKey](#) field in S3BucketConfig to the access key. The value can be either a 32-character plaintext key or a 44-character base64-encoded key.

### HTTP(S) logging (AWS)

When a request to AWS fails or is retried, or Vertica detects a performance degradation, Vertica logs the event in the [UDFS\\_EVENTS](#) system table. The event type for these records is `HttpRequestAttempt`, and the description is a JSON object with more details. For example:

```
-> SELECT filesystem, event, description FROM UDFS_EVENTS;
filesystem | event | description

S3 | HttpRequestAttempt | {"AttemptStartTimeGMT":"2024-01-18 16:45:52.663","RetryCount":0,"HttpMethod":"GET","URIString":"s3://mybucket/s3_2.da
S3 | HttpRequestAttempt | {"AttemptStartTimeGMT":"2024-01-18 16:46:02.663","RetryCount":1,"HttpMethod":"GET","URIString":"s3://mybucket/s3_2.da
(2 rows)
```

To extract fields from this description, use the [MAPJSONEXTRACTOR](#) function:

```
-> SELECT filesystem, event,
 (MapJSONExtractor(description))['RetryCount'] as RetryCount,
 (MapJSONExtractor(description))['HttpStatusCode'] as HttpStatusCode
FROM UDFS_EVENTS;
filesystem | event | RetryCount | HttpStatusCode

S3 | HttpRequestAttempt | 0 | 404
S3 | HttpRequestAttempt | 1 | 206
(2 rows)
```

For details on AWS-specific fields such as `AmzRequestId`, see the [AWS documentation](#).

The [UDFS\\_STATISTICS](#) system table records the accumulated duration for all HTTP requests in the `TOTAL_REQUEST_DURATION_MS` column. This table also provides computed values for average duration and throughput.

#### Examples

The following example sets a database-wide AWS region and credentials:

```
-> ALTER DATABASE DEFAULT SET AWSRegion='us-west-1';
-> ALTER DATABASE DEFAULT SET AWSAuth = 'myaccesskeyid123456:mysecretaccesskey123456789012345678901234';
```

The following example loads data from S3. You can use a glob if all files in the glob can be loaded together. In the following example, `AWS_DataLake` contains only ORC files.

```
-> COPY t FROM 's3://datalake/' ORC;
```

You can specify a list of comma-separated S3 buckets as in the following example. All buckets must be in the same region. To load from more than one region, use separate COPY statements and change the value of `AWSRegion` between calls.

```
-> COPY t FROM 's3://AWS_Data_1/sales.parquet', 's3://AWS_Data_2/sales.parquet' PARQUET;
```

The following example creates a user storage location and a role, so that users without their own S3 credentials can read data from S3 using the server credential.

```
-- set database-level credential (once):
-> ALTER DATABASE DEFAULT SET AWSAuth = 'myaccesskeyid123456:mysecretaccesskey123456789012345678901234';

-> CREATE LOCATION 's3://datalake' SHARED USAGE 'USER' LABEL 's3user';

-> CREATE ROLE ExtUsers;
-- Assign users to this role using GRANT (Role).

-> GRANT READ ON LOCATION 's3://datalake' TO ExtUsers;
```

The configuration properties for a given bucket may differ based on its type. The following `S3BucketConfig` setting is for an AWS bucket (`AWSBucket`) and a Pure Storage bucket (`PureStorageBucket`). `AWSBucket` doesn't specify an endpoint, so Vertica uses the `AWSEndpoint` configuration parameter, which defaults to `s3.amazonaws.com`:

```
=> ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
{
 {
 "bucket": "AWSBucket",
 "region": "us-east-2",
 "protocol": "https",
 "requesterPays": true,
 "serverSideEncryption": "aes256"
 },
 {
 "bucket": "PureStorageBucket",
 "endpoint": "pure.mycorp.net:1234",
 "protocol": "http",
 "enableVirtualAddressing": false
 }
}
```

The following example sets S3BucketCredentials for these two buckets:

```
=> ALTER SESSION SET S3BucketCredentials=
```

```
{
 {
 "bucket": "AWSBucket",
 "accessKey": "<AK0>",
 "secretAccessKey": "<SAK0>",
 "sessionToken": "1234567890"
 },
 {
 "bucket": "PureStorageBucket",
 "accessKey": "<AK1>",
 "secretAccessKey": "<SAK1>"
 }
}
```

The following example sets an STS temporary session token. Vertica uses the session token to access S3 with the specified credentials and bypasses checking for a USER storage location.

```
$ aws sts get-session-token
```

```
{
 "Credentials": {
 "AccessKeyId": "ASIAJZQNDV5727EHDHOQ",
 "SecretAccessKey": "F+xnpkHbst6UPorlGj/iJhO5J2n3Yo7Mp4vYvd",
 "SessionToken": "FOoDYXdzEKv////////wEaDMWKxakEkGyuDH0UjyKsAe6/3REgW5VbWtpuYyVvSnEK1jzGPHI/jPOPNT7Kd+ftSnD3qdaQ7j28SUW9Y",
 "Expiration": "2018-07-18T05:56:33Z"
 }
}
```

```
$ vsql
```

```
=> ALTER SESSION SET AWSSAuth = 'ASIAJZQNDV5727EHDHOQ:F+xnpkHbst6UPorlGj/iJhO5J2n3Yo7Mp4vYvd';
```

```
=> ALTER SESSION SET AWSSessionToken = 'FOoDYXdzEKv////////wEaDMWKxakEkGyuDH0UjyKsAe6/3REgW5VbWtpuYyVvSnEK1jzGPHI/jPOPNT7Kd
```

[Per-Bucket S3 Configurations](#)

In this section

- [Per-bucket S3 configurations](#)

Per-bucket S3 configurations

You can manage configurations and credentials for individual buckets with the S3BucketConfig and S3BucketCredentials configuration parameters. These parameters each take a JSON object, whose respective properties behave like the related S3 configuration parameters.

For example, you can create a different configuration for each of your S3 buckets by setting `S3BucketConfig` at the database level with [ALTER DATABASE](#). The following `S3BucketConfig` specifies several common bucket properties:

```
-> ALTER DATABASE DEFAULT SET S3BucketConfig=
{
 "bucket": "exampleAWS",
 "region": "us-east-2",
 "protocol": "https",
 "requesterPays": true
},
{
 "bucket": "examplePureStorage",
 "endpoint": "pure.mycorp.net:1234",
 "protocol": "http",
 "enableVirtualAddressing": false
}
;
```

Users can then access a bucket by setting `S3BucketCredentials` at the session level with [ALTER SESSION](#). The following `S3BucketCredentials` specifies all properties and authenticates to both `exampleAWS` and `examplePureStorage` simultaneously:

```
-> ALTER SESSION SET S3BucketCredentials=
{
 "bucket": "exampleAWS",
 "accessKey": "<AK0>",
 "secretAccessKey": "<SAK0>",
 "sessionToken": "1234567890"
},
{
 "bucket": "examplePureStorage",
 "accessKey": "<AK1>",
 "secretAccessKey": "<SAK1>"
}
;
```

### Recommended usage

The recommended usage is as follows:

- Define in your S3 storage system one set of credentials per principal, per storage system.
- It is often most convenient to set `S3BucketConfig` once at the database level and have users authenticate by setting `S3BucketCredentials` at the session level.
- To access buckets outside those configured at the database level, set both `S3BucketConfig` and `S3BucketCredentials` at the session level.

If you cannot define credentials for your S3 storage, you can set `S3BucketCredentials` or `AWSAuth` at the database level with [ALTER DATABASE](#), but this comes with certain drawbacks:

- Storing credentials statically in another location (in this case, in the Vertica catalog) always incurs additional risk.
- This increases overhead for the dbadmin, who needs to create user storage locations and grant access to each user or role.
- Users share one set of credentials, increasing the potential impact if the credentials are compromised.

### Note

If you set `AWSEndpoint` to a non-Amazon S3 storage system like Pure Storage or MinIO and you want to configure `S3BucketConfig` for real Amazon S3, the following requirements apply:

- If your real Amazon S3 region is not `us-east-1` (the default), you must specify the `region`.
- Set `endpoint` to an empty string ( `""` ).

```

=> ALTER DATABASE DEFAULT SET S3BucketConfig='
{
 "bucket": "additionalAWSBucket",
 "region": "us-east-2",
 "endpoint": ""
}
';

```

### Precedence of per-bucket and standard parameters

Vertica uses the following rules to determine the effective set of properties for an S3 connection:

- If set, `S3BucketCredentials` takes priority over its standard parameters. `S3BucketCredentials` is checked first at the session level and then at the database level.
- The level/source of the S3 credential parameters determines the source of the S3 configuration parameters:
  - If credentials come from the session level, then the configuration can come from either the session or database level (with the session level taking priority).
  - If your credentials come from the database level, then the configuration can only come from the database level.
- If `S3BucketConfig` is set, it takes priority over its standard parameters. If an `S3BucketConfig` property isn't specified, Vertica falls back to the missing property's equivalent parameter. For example, if `S3BucketConfig` specifies every property except `protocol`, Vertica falls back to the standard parameter `AWSEnableHttps`.

### Examples

#### Multiple buckets

This example configures a real Amazon S3 bucket `AWSBucket` and a Pure Storage bucket `PureStorageBucket` with `S3BucketConfig`.

`AWSBucket` does not specify an `endpoint` or protocol, so Vertica falls back to `AWSEndpoint` (defaults to `s3.amazonaws.com`) and `AWSEnableHttps` (defaults to `1`).

In this example environment, access to the `PureStorageBucket` is over a secure network, so HTTPS is disabled:

```

=> ALTER DATABASE DEFAULT SET S3BucketConfig='
{
 "bucket": "AWSBucket",
 "region": "us-east-2"
},
{
 "bucket": "PureStorageBucket",
 "endpoint": "pure.mycorp.net:1234",
 "protocol": "http",
 "enableVirtualAddressing": false
}
';

```

Bob can then set `S3BucketCredentials` at the session level to authenticate to `AWSBucket`:

```

=> ALTER SESSION SET S3BucketCredentials='
{
 "bucket": "AWSBucket",
 "accessKey": "<AK0>",
 "secretAccessKey": "<SAK0>",
 "sessionToken": "1234567890"
}
';

```

Similarly, Alice can authenticate to `PureStorageBucket`:

```
-> ALTER SESSION SET S3BucketCredentials=
```

```
{
 "bucket": "PureStorageBucket",
 "accessKey": "<AK1>",
 "secretAccessKey": "<SAK1>"
}
```

Charlie provides credentials for both [AWSBucket](#) and [PureStorageBucket](#) and authenticates to them simultaneously. This allows him to perform cross-endpoint joins, export from one bucket to another, etc.

```
-> ALTER SESSION SET S3BucketCredentials=
```

```
{
 "bucket": "AWSBucket",
 "accessKey": "<AK0>",
 "secretAccessKey": "<SAK0>",
 "sessionToken": "1234567890"
},
{
 "bucket": "PureStorageBucket",
 "accessKey": "<AK1>",
 "secretAccessKey": "<SAK1>"
}
```

### S3 server-side encryption

S3 has three types of server-side encryption: SSE-S3, SSE-KMS, and SSE-C. The following example configures access using SSE-KMS:

```
-> ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
{
 "bucket": "AWSBucket",
 "region": "us-east-2",
 "serverSideEncryption": "aws:kms",
 "sseKmsKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
}
```

For more information, see [Server-Side Encryption](#).

### Non-amazon S3 storage with AWSEndpoint and S3BucketConfig

If AWSEndpoint is set to a non-Amazon S3 bucket like Pure Storage or MinIO and you want to configure S3BucketConfig for a real Amazon S3 bucket, the following requirements apply:

- If your real Amazon S3 region is not [us-east-1](#) (the default), you must specify the [region](#).
- Set [endpoint](#) to an empty string ( "" ).

In this example, AWSEndpoint is set to a Pure Storage bucket.

```
-> ALTER DATABASE DEFAULT SET AWSEndpoint=pure.mycorp.net:1234;
```

To configure S3BucketConfig for a real Amazon S3 bucket [realAmazonS3Bucket](#) in region " [us-east-2](#) ":

```
-> ALTER DATABASE DEFAULT SET S3BucketConfig=
```

```
{
 "bucket": "realAmazonS3Bucket",
 "region": "us-east-2",
 "endpoint": ""
}
```

# Functions

Functions return information from the database. This section describes functions that Vertica supports. Except for meta-functions, you can use a function anywhere an expression is allowed.

Meta-functions usually access the internal state of Vertica. They can be used in a top-level SELECT statement only, and the statement cannot contain other clauses such as FROM or WHERE. Meta-functions are labeled on their reference pages.

The Behavior Type section on each reference page categorizes the function's return behavior as one or more of the following:

- **Immutable** (invariant): When run with a given set of arguments, immutable functions always produce the same result, regardless of environment or session settings such as locale.
- **Stable** : When run with a given set of arguments, stable functions produce the same result within a single query or scan operation. However, a stable function can produce different results when issued under different environments or at different times, such as change of locale and time zone—for example, [SYSDATE](#).
- **Volatile** : Regardless of their arguments or environment, volatile functions can return a different result with each invocation—for example, [UUID\\_GENERATE](#).

List of all functions

The following list contains all Vertica SQL functions.

Jump to letter: [A](#) - [B](#) - [C](#) - [D](#) - [E](#) - [F](#) - [G](#) - [H](#) - [I](#) - [J](#) - [K](#) - [L](#) - [M](#) - [N](#) - [O](#) - [P](#) - [Q](#) - [R](#) - [S](#) - [T](#) - [U](#) - [V](#) - [W](#) - [X](#) - [Y](#) - [Z](#)

A

## [ABS](#)

Returns the absolute value of the argument. [ [Mathematical functions](#) ]

## [ACOS](#)

Returns a DOUBLE PRECISION value representing the trigonometric inverse cosine of the argument. [ [Mathematical functions](#) ]

## [ACOSH](#)

Returns a DOUBLE PRECISION value that represents the inverse (arc) hyperbolic cosine of the function argument. [ [Mathematical functions](#) ]

## [ACTIVE\\_SCHEDULER\\_NODE](#)

Returns the active scheduler node. [ [Stored procedure functions](#) ]

## [ADD\\_MONTHS](#)

Adds the specified number of months to a date and returns the sum as a DATE. [ [Date/time functions](#) ]

## [ADVANCE\\_EPOCH](#)

Manually closes the current epoch and begins a new epoch. [ [Epoch functions](#) ]

## [AGE\\_IN\\_MONTHS](#)

Returns the difference in months between two dates, expressed as an integer. [ [Date/time functions](#) ]

## [AGE\\_IN\\_YEARS](#)

Returns the difference in years between two dates, expressed as an integer. [ [Date/time functions](#) ]

## [ALTER\\_LOCATION\\_LABEL](#)

Adds a label to a storage location, or changes or removes an existing label. [ [Storage functions](#) ]

## [ALTER\\_LOCATION\\_SIZE](#)

Resizes on one node, all nodes in a subcluster, or all nodes in the database. [ [Eon Mode functions](#) ]

## [ALTER\\_LOCATION\\_USE](#)

Alters the type of data that a storage location holds. [ [Storage functions](#) ]

## [ANALYZE\\_CONSTRAINTS](#)

Analyzes and reports on constraint violations within the specified scope. [ [Table functions](#) ]

## [ANALYZE\\_CORRELATIONS](#)

This function is deprecated and will be removed in a future release. [ [Table functions](#) ]

## [ANALYZE\\_EXTERNAL\\_ROW\\_COUNT](#)

Calculates the exact number of rows in an external table. [ [Statistics management functions](#) ]

## [ANALYZE\\_STATISTICS](#)

Collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table. [ [Statistics management functions](#) ]

## [ANALYZE\\_STATISTICS\\_PARTITION](#)

Collects and aggregates data samples and storage information for a range of partitions in the specified table. [ [Statistics management functions](#) ]

### **[ANALYZE\\_WORKLOAD](#)**

Runs Workload Analyzer, a utility that analyzes system information held in system tables. [ [Workload management functions](#) ]

### **[APPLY\\_AVG](#)**

Returns the average of all elements in a with numeric values. [ [Collection functions](#) ]

### **[APPLY\\_BISECTING\\_KMEANS](#)**

Applies a trained bisecting k-means model to an input relation, and assigns each new data point to the closest matching cluster in the trained model. [ [Transformation functions](#) ]

### **[APPLY\\_COUNT \(ARRAY\\_COUNT\)](#)**

Returns the total number of non-null elements in a. [ [Collection functions](#) ]

### **[APPLY\\_COUNT\\_ELEMENTS \(ARRAY\\_LENGTH\)](#)**

Returns the total number of elements in a , including NULLs. [ [Collection functions](#) ]

### **[APPLY\\_IFOREST](#)**

Applies an isolation forest (iForest) model to an input relation. [ [Transformation functions](#) ]

### **[APPLY\\_INVERSE\\_PCA](#)**

Inverts the APPLY\_PCA-generated transform back to the original coordinate system. [ [Transformation functions](#) ]

### **[APPLY\\_INVERSE\\_SVD](#)**

Transforms the data back to the original domain. [ [Transformation functions](#) ]

### **[APPLY\\_KMEANS](#)**

Assigns each row of an input relation to a cluster center from an existing k-means model. [ [Transformation functions](#) ]

### **[APPLY\\_KPROTOTYPES](#)**

Assigns each row of an input relation to a cluster center from an existing k-prototypes model. [ [Transformation functions](#) ]

### **[APPLY\\_MAX](#)**

Returns the largest non-null element in a. [ [Collection functions](#) ]

### **[APPLY\\_MIN](#)**

Returns the smallest non-null element in a. [ [Collection functions](#) ]

### **[APPLY\\_NORMALIZE](#)**

A UDTF function that applies the normalization parameters saved in a model to a set of specified input columns. [ [Transformation functions](#) ]

### **[APPLY\\_ONE\\_HOT\\_ENCODER](#)**

A user-defined transform function (UDTF) that loads the one hot encoder model and writes out a table that contains the encoded columns. [ [Transformation functions](#) ]

### **[APPLY\\_PCA](#)**

Transforms the data using a PCA model. [ [Transformation functions](#) ]

### **[APPLY\\_SUM](#)**

Computes the sum of all elements in a of numeric values (INTEGER, FLOAT, NUMERIC, or INTERVAL). [ [Collection functions](#) ]

### **[APPLY\\_SVD](#)**

Transforms the data using an SVD model. [ [Transformation functions](#) ]

### **[APPROXIMATE\\_COUNT\\_DISTINCT](#)**

Returns the number of distinct non-NULL values in a data set. [ [Aggregate functions](#) ]

### **[APPROXIMATE\\_COUNT\\_DISTINCT\\_OF\\_SYNOPSIS](#)**

Calculates the number of distinct non-NULL values from the synopsis objects created by APPROXIMATE\_COUNT\_DISTINCT\_SYNOPSIS. [ [Aggregate functions](#) ]

### **[APPROXIMATE\\_COUNT\\_DISTINCT\\_SYNOPSIS](#)**

Summarizes the information of distinct non-NULL values and materializes the result set in a VARBINARY or LONG VARBINARY synopsis object. [ [Aggregate functions](#) ]

### **[APPROXIMATE\\_COUNT\\_DISTINCT\\_SYNOPSIS\\_MERGE](#)**

Aggregates multiple synopses into one new synopsis. [ [Aggregate functions](#) ]

### **[APPROXIMATE\\_MEDIAN \[aggregate\]](#)**

Computes the approximate median of an expression over a group of rows. [ [Aggregate functions](#) ]

### **[APPROXIMATE\\_PERCENTILE \[aggregate\]](#)**

Computes the approximate percentile of an expression over a group of rows. [ [Aggregate functions](#) ]

### **[APPROXIMATE\\_QUANTILES](#)**

Computes an array of weighted, approximate percentiles of a column within some user-specified error. [ [Aggregate functions](#) ]

### **[ARGMAX \[analytic\]](#)**

This function is patterned after the mathematical function  $\operatorname{argmax}(f(x))$ , which returns the value of  $x$  that maximizes  $f(x)$ . [ [Analytic functions](#) ]

### **[ARGMAX\\_AGG](#)**

Takes two arguments `target` and `arg`, where both are columns or column expressions in the queried dataset. [ [Aggregate functions](#) ]

### **[ARGMIN \[analytic\]](#)**

This function is patterned after the mathematical function  $\operatorname{argmin}(f(x))$ , which returns the value of  $x$  that minimizes  $f(x)$ . [ [Analytic functions](#) ]

### **[ARGMIN\\_AGG](#)**

Takes two arguments `target` and `arg`, where both are columns or column expressions in the queried dataset. [ [Aggregate functions](#) ]

### **[ARIMA](#)**

Creates and trains an autoregressive integrated moving average (ARIMA) model from a time series with consistent timesteps. [ [Machine learning algorithms](#) ]

### **[ARRAY\\_CAT](#)**

Concatenates two arrays of the same element type and dimensionality. [ [Collection functions](#) ]

### **[ARRAY\\_CONTAINS](#)**

Returns true if the specified element is found in the array and false if not. [ [Collection functions](#) ]

### **[ARRAY\\_DIMS](#)**

Returns the dimensionality of the input array. [ [Collection functions](#) ]

### **[ARRAY\\_FIND](#)**

Returns the ordinal position of a specified element in an array, or -1 if not found. [ [Collection functions](#) ]

### **[ASCII](#)**

Converts the first character of a VARCHAR datatype to an INTEGER. [ [String functions](#) ]

### **[ASIN](#)**

Returns a DOUBLE PRECISION value representing the trigonometric inverse sine of the argument. [ [Mathematical functions](#) ]

### **[ASINH](#)**

Returns a DOUBLE PRECISION value that represents the inverse (arc) hyperbolic sine of the function argument. [ [Mathematical functions](#) ]

### **[ATAN](#)**

Returns a DOUBLE PRECISION value representing the trigonometric inverse tangent of the argument. [ [Mathematical functions](#) ]

### **[ATAN2](#)**

Returns a DOUBLE PRECISION value representing the trigonometric inverse tangent of the arithmetic dividend of the arguments. [ [Mathematical functions](#) ]

### **[ATANH](#)**

Returns a DOUBLE PRECISION value that represents the inverse hyperbolic tangent of the function argument. [ [Mathematical functions](#) ]

### **[AUDIT](#)**

Returns the raw data size (in bytes) of a database, schema, or table as it is counted in an audit of the database size. [ [License functions](#) ]

### **[AUDIT\\_FLEX](#)**

Returns the estimated ROS size of `__raw__` columns, equivalent to the export size of the flex data in the audited objects. [ [License functions](#) ]

### **[AUDIT\\_LICENSE\\_SIZE](#)**

Triggers an immediate audit of the database size to determine if it is in compliance with the raw data storage allowance included in your Vertica licenses. [ [License functions](#) ]

### **[AUDIT\\_LICENSE\\_TERM](#)**

Triggers an immediate audit to determine if the Vertica license has expired. [ [License functions](#) ]

### **[AUTOREGRESSOR](#)**

Creates an autoregressive (AR) model from a stationary time series with consistent timesteps that can then be used for prediction via `PREDICT_AR`. [ [Machine learning algorithms](#) ]

### **[AVG \[aggregate\]](#)**

Computes the average (arithmetic mean) of an expression over a group of rows. [ [Aggregate functions](#) ]

### **[AVG \[analytic\]](#)**

Computes an average of an expression in a group within a. [ [Analytic functions](#) ]

### **[AZURE\\_TOKEN\\_CACHE\\_CLEAR](#)**

Clears the cached access token for Azure. [ [Cloud functions](#) ]

## **B**

### **[BACKGROUND\\_DEPOT\\_WARMING](#)**

Vertica version 10.0.0 removes support for foreground depot warming. [ [Eon Mode functions](#) ]

## **[BALANCE](#)**

Returns a view with an equal distribution of the input data based on the response\_column. [ [Data preparation](#) ]

## **[BISECTING\\_KMEANS](#)**

Executes the bisecting k-means algorithm on an input relation. [ [Machine learning algorithms](#) ]

## **[BIT\\_AND](#)**

Takes the bitwise AND of all non-null input values. [ [Aggregate functions](#) ]

## **[BIT\\_LENGTH](#)**

Returns the length of the string expression in bits (bytes \* 8) as an INTEGER. [ [String functions](#) ]

## **[BIT\\_OR](#)**

Takes the bitwise OR of all non-null input values. [ [Aggregate functions](#) ]

## **[BIT\\_XOR](#)**

Takes the bitwise XOR of all non-null input values. [ [Aggregate functions](#) ]

## **[BITCOUNT](#)**

Returns the number of one-bits (sometimes referred to as set-bits) in the given VARBINARY value. [ [String functions](#) ]

## **[BITSTRING\\_TO\\_BINARY](#)**

Translates the given VARCHAR bitstring representation into a VARBINARY value. [ [String functions](#) ]

## **[BOOL\\_AND \[aggregate\]](#)**

Processes Boolean values and returns a Boolean value result. [ [Aggregate functions](#) ]

## **[BOOL\\_AND \[analytic\]](#)**

Returns the Boolean value of an expression within a. [ [Analytic functions](#) ]

## **[BOOL\\_OR \[aggregate\]](#)**

Processes Boolean values and returns a Boolean value result. [ [Aggregate functions](#) ]

## **[BOOL\\_OR \[analytic\]](#)**

Returns the Boolean value of an expression within a. [ [Analytic functions](#) ]

## **[BOOL\\_XOR \[aggregate\]](#)**

Processes Boolean values and returns a Boolean value result. [ [Aggregate functions](#) ]

## **[BOOL\\_XOR \[analytic\]](#)**

Returns the Boolean value of an expression within a. [ [Analytic functions](#) ]

## **[BTRIM](#)**

Removes the longest string consisting only of specified characters from the start and end of a string. [ [String functions](#) ]

## **[BUILD\\_FLEXTABLE\\_VIEW](#)**

Creates, or re-creates, a view for a default or user-defined keys table, ignoring any empty keys. [ [Flex data functions](#) ]

## **C**

### **[CALENDAR\\_HIERARCHY\\_DAY](#)**

Groups DATE partition keys into a hierarchy of years, months, and days. [ [Partition functions](#) ]

### **[CANCEL\\_DEPOT\\_WARMING](#)**

Cancels depot warming on a node. [ [Eon Mode functions](#) ]

### **[CANCEL\\_DRAIN\\_SUBCLUSTER](#)**

Cancels the draining of a subcluster or subclusters. [ [Eon Mode functions](#) ]

### **[CANCEL\\_REBALANCE\\_CLUSTER](#)**

Stops any rebalance task that is currently in progress or is waiting to execute. [ [Cluster functions](#) ]

### **[CANCEL\\_REFRESH](#)**

Cancels refresh-related internal operations initiated by START\_REFRESH and REFRESH. [ [Session functions](#) ]

### **[CBRT](#)**

Returns the cube root of the argument. [ [Mathematical functions](#) ]

### **[CEILING](#)**

Rounds up the returned value up to the next whole number. [ [Mathematical functions](#) ]

### **[CHANGE\\_CURRENT\\_STATEMENT\\_RUNTIME\\_PRIORITY](#)**

Changes the run-time priority of an active query. [ [Workload management functions](#) ]

### **[CHANGE\\_MODEL\\_STATUS](#)**

Changes the status of a registered model. [ [Model management](#) ]

## **[CHANGE\\_RUNTIME\\_PRIORITY](#)**

Changes the run-time priority of a query that is actively running. [ [Workload management functions](#) ]

## **[CHARACTER\\_LENGTH](#)**

The CHARACTER\_LENGTH() function:. [ [String functions](#) ]

## **[CHI\\_SQUARED](#)**

Computes the conditional chi-Square independence test on two categorical variables to find the likelihood that the two variables are independent. [ [Data preparation](#) ]

## **[CHR](#)**

Converts the first character of an INTEGER datatype to a VARCHAR. [ [String functions](#) ]

## **[CLEAN\\_COMMUNAL\\_STORAGE](#)**

Marks for deletion invalid data in communal storage, often data that leaked due to an event where Vertica cleanup mechanisms failed. [ [Eon Mode functions](#) ]

## **[CLEAR\\_CACHES](#)**

Clears the Vertica internal cache files. [ [Storage functions](#) ]

## **[CLEAR\\_DATA\\_COLLECTOR](#)**

Clears all memory and disk records from Data Collector tables and logs, and resets collection statistics in system table DATA\_COLLECTOR. [ [Data Collector functions](#) ]

## **[CLEAR\\_DATA\\_DEPOT](#)**

Deletes the specified depot data. [ [Eon Mode functions](#) ]

## **[CLEAR\\_DEPOT\\_ANTI\\_PIN\\_POLICY\\_PARTITION](#)**

Removes an anti-pinning policy from the specified partition. [ [Eon Mode functions](#) ]

## **[CLEAR\\_DEPOT\\_ANTI\\_PIN\\_POLICY\\_PROJECTION](#)**

Removes an anti-pinning policy from the specified projection. [ [Eon Mode functions](#) ]

## **[CLEAR\\_DEPOT\\_ANTI\\_PIN\\_POLICY\\_TABLE](#)**

Removes an anti-pinning policy from the specified table. [ [Eon Mode functions](#) ]

## **[CLEAR\\_DEPOT\\_PIN\\_POLICY\\_PARTITION](#)**

Clears a depot pinning policy from the specified table or projection partitions. [ [Eon Mode functions](#) ]

## **[CLEAR\\_DEPOT\\_PIN\\_POLICY\\_PROJECTION](#)**

Clears a depot pinning policy from the specified projection. [ [Eon Mode functions](#) ]

## **[CLEAR\\_DEPOT\\_PIN\\_POLICY\\_TABLE](#)**

Clears a depot pinning policy from the specified table. [ [Eon Mode functions](#) ]

## **[CLEAR\\_DIRECTED\\_QUERY\\_USAGE](#)**

Resets the counter in the DIRECTED\_QUERY\_STATUS table. [ [Directed queries functions](#) ]

## **[CLEAR\\_FETCH\\_QUEUE](#)**

Removes all entries or entries for a specific transaction from the queue of fetch requests of data from the communal storage. [ [Eon Mode functions](#) ]

## **[CLEAR\\_HDFS\\_CACHES](#)**

Clears the configuration information copied from HDFS and any cached connections. [ [Hadoop functions](#) ]

## **[CLEAR\\_OBJECT\\_STORAGE\\_POLICY](#)**

Removes a user-defined storage policy from the specified database, schema or table. [ [Storage functions](#) ]

## **[CLEAR\\_PROFILING](#)**

Clears from memory data for the specified profiling type. [ [Profiling functions](#) ]

## **[CLEAR\\_PROJECTION\\_REFRESHES](#)**

Clears information projection refresh history from system table PROJECTION\_REFRESHES. [ [Projection functions](#) ]

## **[CLEAR\\_RESOURCE\\_REJECTIONS](#)**

Clears the content of the RESOURCE\_REJECTIONS and DISK\_RESOURCE\_REJECTIONS system tables. [ [Database functions](#) ]

## **[CLOCK\\_TIMESTAMP](#)**

Returns a value of type TIMESTAMP WITH TIMEZONE that represents the current system-clock time. [ [Date/time functions](#) ]

## **[CLOSE\\_ALL\\_RESULTSETS](#)**

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets. [ [Client connection functions](#) ]

## **[CLOSE\\_ALL\\_SESSIONS](#)**

Closes all external sessions except the one that issues this function. [ [Session functions](#) ]

## **[CLOSE\\_RESULTSET](#)**

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets. [ [Client connection functions](#) ]

## **[CLOSE\\_SESSION](#)**

Interrupts the specified external session, rolls back the current transaction if any, and closes the socket. [ [Session functions](#) ]

## **[CLOSE\\_USER\\_SESSIONS](#)**

Stops the session for a user, rolls back any transaction currently running, and closes the connection. [ [Session functions](#) ]

## **[COALESCE](#)**

Returns the value of the first non-null expression in the list. [ [NULL-handling functions](#) ]

## **[COLLATION](#)**

Applies a collation to two or more strings. [ [String functions](#) ]

## **[COMPACT\\_STORAGE](#)**

Bundles existing data (.fdb) and index (.pidx) files into the .gt file format. [ [Database functions](#) ]

## **[COMPUTE\\_FLEXTABLE\\_KEYS](#)**

Computes the virtual columns (keys and values) from flex table VMap data. [ [Flex data functions](#) ]

## **[COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)**

Combines the functionality of BUILD\_FLEXTABLE\_VIEW and COMPUTE\_FLEXTABLE\_KEYS to compute virtual columns (keys) from the VMap data of a flex table and construct a view. [ [Flex data functions](#) ]

## **[CONCAT](#)**

Concatenates two strings and returns a varchar data type. [ [String functions](#) ]

## **[CONDITIONAL\\_CHANGE\\_EVENT](#) [analytic]**

Assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row. [ [Analytic functions](#) ]

## **[CONDITIONAL\\_TRUE\\_EVENT](#) [analytic]**

Assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true. [ [Analytic functions](#) ]

## **[CONFUSION\\_MATRIX](#)**

Computes the confusion matrix of a table with observed and predicted values of a response variable. [ [Model evaluation](#) ]

## **[CONTAINS](#)**

Returns true if the specified element is found in the collection and false if not. [ [Collection functions](#) ]

## **[COPY\\_PARTITIONS\\_TO\\_TABLE](#)**

Copies partitions from one table to another. [ [Partition functions](#) ]

## **[COPY\\_TABLE](#)**

Copies one table to another. [ [Table functions](#) ]

## **[CORR](#)**

Returns the DOUBLE PRECISION coefficient of correlation of a set of expression pairs, as per the Pearson correlation coefficient. [ [Aggregate functions](#) ]

## **[CORR\\_MATRIX](#)**

Takes an input relation with numeric columns, and calculates the Pearson Correlation Coefficient between each pair of its input columns. [ [Data preparation](#) ]

## **[COS](#)**

Returns a DOUBLE PRECISION value that represents the trigonometric cosine of the passed parameter. [ [Mathematical functions](#) ]

## **[COSH](#)**

Returns a DOUBLE PRECISION value that represents the hyperbolic cosine of the passed parameter. [ [Mathematical functions](#) ]

## **[COT](#)**

Returns a DOUBLE PRECISION value representing the trigonometric cotangent of the argument. [ [Mathematical functions](#) ]

## **[COUNT](#) [aggregate]**

Returns as a BIGINT the number of rows in each group where the expression is not NULL. [ [Aggregate functions](#) ]

## **[COUNT](#) [analytic]**

Counts occurrences within a group within a. [ [Analytic functions](#) ]

## **[COVAR\\_POP](#)**

Returns the population covariance for a set of expression pairs. [ [Aggregate functions](#) ]

## **[COVAR\\_SAMP](#)**

Returns the sample covariance for a set of expression pairs. [ [Aggregate functions](#) ]

#### **[CROSS\\_VALIDATE](#)**

Performs k-fold cross validation on a learning algorithm using an input relation, and grid search for hyper parameters. [ [Model evaluation](#) ]

#### **[CUME\\_DIST \[analytic\]](#)**

Calculates the cumulative distribution, or relative rank, of the current row with regard to other rows in the same partition within a . [ [Analytic functions](#) ]

#### **[CURRENT\\_DATABASE](#)**

Returns the name of the current database, equivalent to DBNAME. [ [System information functions](#) ]

#### **[CURRENT\\_DATE](#)**

Returns the date (date-type value) on which the current transaction started. [ [Date/time functions](#) ]

#### **[CURRENT\\_LOAD\\_SOURCE](#)**

When called within the scope of a COPY statement, returns the file name or path part used for the load. [ [System information functions](#) ]

#### **[CURRENT\\_SCHEMA](#)**

Returns the name of the current schema. [ [System information functions](#) ]

#### **[CURRENT\\_SESSION](#)**

Returns the ID of the current client session. [ [System information functions](#) ]

#### **[CURRENT\\_TIME](#)**

Returns a value of type TIME WITH TIMEZONE that represents the start of the current transaction. [ [Date/time functions](#) ]

#### **[CURRENT\\_TIMESTAMP](#)**

Returns a value of type TIME WITH TIMEZONE that represents the start of the current transaction. [ [Date/time functions](#) ]

#### **[CURRENT\\_TRANS\\_ID](#)**

Returns the ID of the transaction currently in progress. [ [System information functions](#) ]

#### **[CURRENT\\_USER](#)**

Returns a VARCHAR containing the name of the user who initiated the current database connection. [ [System information functions](#) ]

#### **[CURVAL](#)**

Returns the last value across all nodes that was set by NEXTVAL on this sequence in the current session. [ [Sequence functions](#) ]

#### **D**

#### **[DATA\\_COLLECTOR\\_HELP](#)**

Returns online usage instructions about the Data Collector, the V\_MONITOR.DATA\_COLLECTOR system table, and the Data Collector control functions. [ [Data Collector functions](#) ]

#### **[DATE](#)**

Converts the input value to a DATE data type. [ [Date/time functions](#) ]

#### **[DATE\\_PART](#)**

Extracts a sub-field such as year or hour from a date/time expression, equivalent to the the SQL-standard function EXTRACT. [ [Date/time functions](#) ]

#### **[DATE\\_TRUNC](#)**

Truncates date and time values to the specified precision. [ [Date/time functions](#) ]

#### **[DATEDIFF](#)**

Returns the time span between two dates, in the intervals specified. [ [Date/time functions](#) ]

#### **[DAY](#)**

Returns as an integer the day of the month from the input value. [ [Date/time functions](#) ]

#### **[DAYOFMONTH](#)**

Returns the day of the month as an integer. [ [Date/time functions](#) ]

#### **[DAYOFWEEK](#)**

Returns the day of the week as an integer, where Sunday is day 1. [ [Date/time functions](#) ]

#### **[DAYOFWEEK\\_ISO](#)**

Returns the ISO 8061 day of the week as an integer, where Monday is day 1. [ [Date/time functions](#) ]

#### **[DAYOFYEAR](#)**

Returns the day of the year as an integer, where January 1 is day 1. [ [Date/time functions](#) ]

#### **[DAYS](#)**

Returns the integer value of the specified date, where 1 AD is 1. [ [Date/time functions](#) ]

#### **[DBNAME \(function\)](#)**

Returns the name of the current database, equivalent to CURRENT\_DATABASE. [ [System information functions](#) ]

## **[DECODE](#)**

Compares expression to each search value one by one. [ [String functions](#) ]

## **[DEGREES](#)**

Converts an expression from radians to fractional degrees, or from degrees, minutes, and seconds to fractional degrees. [ [Mathematical functions](#) ]

## **[DELETE\\_TOKENIZER\\_CONFIG\\_FILE](#)**

Deletes a tokenizer configuration file. [ [Text search functions](#) ]

## **[DEMOTE\\_SUBCLUSTER\\_TO\\_SECONDARY](#)**

Converts a to a . [ [Eon Mode functions](#) ]

## **[DENSE\\_RANK](#) [analytic]**

Within each window partition, ranks all rows in the query results set according to the order specified by the window's ORDER BY clause. [ [Analytic functions](#) ]

## **[DESCRIBE\\_LOAD\\_BALANCE\\_DECISION](#)**

Evaluates if any load balancing routing rules apply to a given IP address and This function is useful when you are evaluating connection load balancing policies you have created, to ensure they work the way you expect them to. [ [Client connection functions](#) ]

## **[DESIGNER\\_ADD\\_DESIGN\\_QUERIES](#)**

Reads and evaluates queries from an input file, and adds the queries that it accepts to the specified design. [ [Database Designer functions](#) ]

## **[DESIGNER\\_ADD\\_DESIGN\\_QUERIES\\_FROM\\_RESULTS](#)**

Executes the specified query and evaluates results in the following columns:. [ [Database Designer functions](#) ]

## **[DESIGNER\\_ADD\\_DESIGN\\_QUERY](#)**

Reads and parses the specified query, and if accepted, adds it to the design. [ [Database Designer functions](#) ]

## **[DESIGNER\\_ADD\\_DESIGN\\_TABLES](#)**

Adds the specified tables to a design. [ [Database Designer functions](#) ]

## **[DESIGNER\\_CANCEL\\_POPULATE\\_DESIGN](#)**

Cancels population or deployment operation for the specified design if it is currently running. [ [Database Designer functions](#) ]

## **[DESIGNER\\_CREATE\\_DESIGN](#)**

Creates a design with the specified name. [ [Database Designer functions](#) ]

## **[DESIGNER\\_DESIGN\\_PROJECTION\\_ENCODINGS](#)**

Analyzes encoding in the specified projections, creates a script to implement encoding recommendations, and optionally deploys the recommendations. [ [Database Designer functions](#) ]

## **[DESIGNER\\_DROP\\_ALL\\_DESIGNS](#)**

Removes all Database Designer-related schemas associated with the current user. [ [Database Designer functions](#) ]

## **[DESIGNER\\_DROP\\_DESIGN](#)**

Removes the schema associated with the specified design and all its contents. [ [Database Designer functions](#) ]

## **[DESIGNER\\_OUTPUT\\_ALL\\_DESIGN\\_PROJECTIONS](#)**

Displays the DDL statements that define the design projections to standard output. [ [Database Designer functions](#) ]

## **[DESIGNER\\_OUTPUT\\_DEPLOYMENT\\_SCRIPT](#)**

Displays the deployment script for the specified design to standard output. [ [Database Designer functions](#) ]

## **[DESIGNER\\_RESET\\_DESIGN](#)**

Discards all run-specific information of the previous Database Designer build or deployment of the specified design but keeps its configuration. [ [Database Designer functions](#) ]

## **[DESIGNER\\_RUN\\_POPULATE\\_DESIGN\\_AND\\_DEPLOY](#)**

Populates the design and creates the design and deployment scripts. [ [Database Designer functions](#) ]

## **[DESIGNER\\_SET\\_DESIGN\\_KSAFETY](#)**

Sets K-safety for a comprehensive design and stores the K-safety value in the DESIGNS table. [ [Database Designer functions](#) ]

## **[DESIGNER\\_SET\\_DESIGN\\_TYPE](#)**

Specifies whether Database Designer creates a comprehensive or incremental design. [ [Database Designer functions](#) ]

## **[DESIGNER\\_SET\\_OPTIMIZATION\\_OBJECTIVE](#)**

Valid only for comprehensive database designs, specifies the optimization objective Database Designer uses. [ [Database Designer functions](#) ]

## **[DESIGNER\\_SET\\_PROPOSE\\_UNSEGMENTED\\_PROJECTIONS](#)**

Specifies whether a design can include unsegmented projections. [ [Database Designer functions](#) ]

## **[DESIGNER\\_SINGLE\\_RUN](#)**

Evaluates all queries that completed execution within the specified timespan, and returns with a design that is ready for deployment. [[Database Designer functions](#)]

#### **[DESIGNER\\_WAIT\\_FOR\\_DESIGN](#)**

Waits for completion of operations that are populating and deploying the design. [[Database Designer functions](#)]

#### **[DETECT\\_OUTLIERS](#)**

Returns the outliers in a data set based on the outlier threshold. [[Data preparation](#)]

#### **[DISABLE\\_DUPLICATE\\_KEY\\_ERROR](#)**

Disables error messaging when Vertica finds duplicate primary or unique key values at run time (for use with key constraints that are not automatically enabled). [[Table functions](#)]

#### **[DISABLE\\_LOCAL\\_SEGMENTS](#)**

Disables local data segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. [[Cluster functions](#)]

#### **[DISABLE\\_PROFILING](#)**

Disables for the current session collection of profiling data of the specified type. [[Profiling functions](#)]

#### **[DISPLAY\\_LICENSE](#)**

Returns the terms of your Vertica license. [[License functions](#)]

#### **[DISTANCE](#)**

Returns the distance (in kilometers) between two points. [[Mathematical functions](#)]

#### **[DISTANCEV](#)**

Returns the distance (in kilometers) between two points using the Vincenty formula. [[Mathematical functions](#)]

#### **[DO\\_LOGROTATE\\_LOCAL](#)**

Rotates logs and removes rotated logs on the current node. [[Database functions](#)]

#### **[DO\\_TM\\_TASK](#)**

Runs a (TM) operation and commits current transactions. [[Storage functions](#)]

#### **[DROP\\_EXTERNAL\\_ROW\\_COUNT](#)**

Removes external table row count statistics compiled by ANALYZE\_EXTERNAL\_ROW\_COUNT. [[Statistics management functions](#)]

#### **[DROP\\_LICENSE](#)**

Drops a license key from the global catalog. [[Catalog functions](#)]

#### **[DROP\\_LOCATION](#)**

Permanently removes a retired storage location. [[Storage functions](#)]

#### **[DROP\\_PARTITIONS](#)**

Drops the specified table partition keys. [[Partition functions](#)]

#### **[DROP\\_STATISTICS](#)**

Removes statistical data on database projections previously generated by ANALYZE\_STATISTICS. [[Statistics management functions](#)]

#### **[DROP\\_STATISTICS\\_PARTITION](#)**

Removes statistical data on database projections previously generated by ANALYZE\_STATISTICS\_PARTITION. [[Statistics management functions](#)]

#### **[DUMP\\_CATALOG](#)**

Returns an internal representation of the Vertica catalog. [[Catalog functions](#)]

#### **[DUMP\\_LOCKTABLE](#)**

Returns information about deadlocked clients and the resources they are waiting for. [[Database functions](#)]

#### **[DUMP\\_PARTITION\\_KEYS](#)**

Dumps the partition keys of all projections in the system. [[Database functions](#)]

#### **[DUMP\\_PROJECTION\\_PARTITION\\_KEYS](#)**

Dumps the partition keys of the specified projection. [[Partition functions](#)]

#### **[DUMP\\_TABLE\\_PARTITION\\_KEYS](#)**

Dumps the partition keys of all projections for the specified table. [[Partition functions](#)]

E

#### **[EDIT\\_DISTANCE](#)**

Calculates and returns the Levenshtein distance between two strings. [[String functions](#)]

#### **[EMPTYMAP](#)**

Constructs a new VMap with one row but without keys or data. [[Flex map functions](#)]

#### **[ENABLE\\_ELASTIC\\_CLUSTER](#)**

Enables elastic cluster scaling, which makes enlarging or reducing the size of your database cluster more efficient by segmenting a node's data into chunks that can be easily moved to other hosts. [ [Cluster functions](#) ]

#### **[ENABLE\\_LOCAL\\_SEGMENTS](#)**

Enables local storage segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. [ [Cluster functions](#) ]

#### **[ENABLE\\_PROFILING](#)**

Enables collection of profiling data of the specified type for the current session. [ [Profiling functions](#) ]

#### **[ENABLE\\_SCHEDULE](#)**

Enables or disables a schedule. [ [Stored procedure functions](#) ]

#### **[ENABLE\\_TRIGGER](#)**

Enables or disables a trigger. [ [Stored procedure functions](#) ]

#### **[ENABLED\\_ROLE](#)**

Checks whether a Vertica user role is enabled, and returns true or false. [ [Privileges and access functions](#) ]

#### **[ENFORCE\\_OBJECT\\_STORAGE\\_POLICY](#)**

Applies storage policies of the specified object immediately. [ [Storage functions](#) ]

#### **[ERROR\\_RATE](#)**

Using an input table, returns a table that calculates the rate of incorrect classifications and displays them as FLOAT values. [ [Model evaluation](#) ]

#### **[EVALUATE\\_DELETE\\_PERFORMANCE](#)**

Evaluates projections for potential DELETE and UPDATE performance issues. [ [Projection functions](#) ]

#### **[EVENT\\_NAME](#)**

Returns a VARCHAR value representing the name of the event that matched the row. [ [MATCH clause functions](#) ]

#### **[EXECUTE\\_TRIGGER](#)**

Manually executes the stored procedure attached to a trigger. [ [Stored procedure functions](#) ]

#### **[EXP](#)**

Returns the exponential function, e to the power of a number. [ [Mathematical functions](#) ]

#### **[EXPLODE](#)**

Expands the elements of one or more collection columns (ARRAY or SET) into individual table rows, one row per element. [ [Collection functions](#) ]

#### **[EXPONENTIAL\\_MOVING\\_AVERAGE \[analytic\]](#)**

Calculates the exponential moving average (EMA) of expression E with smoothing factor X. [ [Analytic functions](#) ]

#### **[EXPORT\\_CATALOG](#)**

This function and EXPORT\_OBJECTS return equivalent output. [ [Catalog functions](#) ]

#### **[EXPORT\\_DIRECTED\\_QUERIES](#)**

Generates SQL for creating directed queries from a set of input queries. [ [Directed queries functions](#) ]

#### **[EXPORT\\_MODELS](#)**

Exports machine learning models. [ [Model management](#) ]

#### **[EXPORT\\_OBJECTS](#)**

This function and EXPORT\_CATALOG return equivalent output. [ [Catalog functions](#) ]

#### **[EXPORT\\_STATISTICS](#)**

Generates statistics in XML format from data previously collected by ANALYZE\_STATISTICS. [ [Statistics management functions](#) ]

#### **[EXPORT\\_STATISTICS\\_PARTITION](#)**

Generates partition-level statistics in XML format from data previously collected by ANALYZE\_STATISTICS\_PARTITION. [ [Statistics management functions](#) ]

#### **[EXPORT\\_TABLES](#)**

Generates a SQL script that can be used to recreate a logical schema—schemas, tables, constraints, and views—on another cluster. [ [Catalog functions](#) ]

#### **[EXTERNAL\\_CONFIG\\_CHECK](#)**

Tests the Hadoop configuration of a Vertica cluster. [ [Hadoop functions](#) ]

#### **[EXTRACT](#)**

Retrieves sub-fields such as year or hour from date/time values and returns values of type NUMERIC. [ [Date/time functions](#) ]

#### **F**

#### **[FILTER](#)**

Takes an input array and returns an array containing only elements that meet a specified condition. [ [Collection functions](#) ]

## **[FINISH\\_FETCHING\\_FILES](#)**

Fetches to the depot all files that are queued for download from communal storage. [ [Eon Mode functions](#) ]

## **[FIRST\\_VALUE \[analytic\]](#)**

Lets you select the first value of a table or partition (determined by the window-order-clause) without having to use a self join. [ [Analytic functions](#) ]

## **[FLOOR](#)**

Rounds down the returned value to the previous whole number. [ [Mathematical functions](#) ]

## **[FLUSH\\_DATA\\_COLLECTOR](#)**

Waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with disk storage. [ [Data Collector functions](#) ]

## **[FLUSH\\_REAPER\\_QUEUE](#)**

Deletes all data marked for deletion in the database. [ [Eon Mode functions](#) ]

## **G**

## **[GET\\_AHM\\_EPOCH](#)**

Returns the number of the in which the is located. [ [Epoch functions](#) ]

## **[GET\\_AHM\\_TIME](#)**

Returns a TIMESTAMP value representing the. [ [Epoch functions](#) ]

## **[GET\\_AUDIT\\_TIME](#)**

Reports the time when the automatic audit of database size occurs. [ [License functions](#) ]

## **[GET\\_CLIENT\\_LABEL](#)**

Returns the client connection label for the current session. [ [Client connection functions](#) ]

## **[GET\\_COMPLIANCE\\_STATUS](#)**

Displays whether your database is in compliance with your Vertica license agreement. [ [License functions](#) ]

## **[GET\\_CONFIG\\_PARAMETER](#)**

Gets the value of a configuration parameter at the specified level. [ [Database functions](#) ]

## **[GET\\_CURRENT\\_EPOCH](#)**

Returns the number of the current epoch. [ [Epoch functions](#) ]

## **[GET\\_DATA\\_COLLECTOR\\_NOTIFY\\_POLICY](#)**

Lists any notification policies set on a component. [ [Notifier functions](#) ]

## **[GET\\_DATA\\_COLLECTOR\\_POLICY](#)**

Retrieves a brief statement about the retention policy for the specified component. [ [Data Collector functions](#) ]

## **[GET\\_LAST\\_GOOD\\_EPOCH](#)**

Returns the number. [ [Epoch functions](#) ]

## **[GET\\_METADATA](#)**

Returns the metadata of a Parquet file. [ [Hadoop functions](#) ]

## **[GET\\_MODEL\\_ATTRIBUTE](#)**

Extracts either a specific attribute from a model or all attributes from a model. [ [Model management](#) ]

## **[GET\\_MODEL\\_SUMMARY](#)**

Returns summary information of a model. [ [Model management](#) ]

## **[GET\\_NUM\\_ACCEPTED\\_ROWS](#)**

Returns the number of rows loaded into the database for the last completed load for the current session. [ [Session functions](#) ]

## **[GET\\_NUM\\_REJECTED\\_ROWS](#)**

Returns the number of rows that were rejected during the last completed load for the current session. [ [Session functions](#) ]

## **[GET\\_PRIVILEGES\\_DESCRIPTION](#)**

Returns the effective privileges the current user has on an object, including explicit, implicit, inherited, and role-based privileges. [ [Privileges and access functions](#) ]

## **[GET\\_PROJECTION\\_SORT\\_ORDER](#)**

Returns the order of columns in a projection's ORDER BY clause. [ [Projection functions](#) ]

## **[GET\\_PROJECTION\\_STATUS](#)**

Returns information relevant to the status of a :. [ [Projection functions](#) ]

## **[GET\\_PROJECTIONS](#)**

Returns contextual and projection information about projections of the specified anchor table. [ [Projection functions](#) ]

## [GET\\_TOKENIZER\\_PARAMETER](#)

Returns the configuration parameter for a given tokenizer. [ [Text search functions](#) ]

## [GETDATE](#)

Returns the current statement's start date and time as a TIMESTAMP value. [ [Date/time functions](#) ]

## [GETUTCDATE](#)

Returns the current statement's start date and time as a TIMESTAMP value. [ [Date/time functions](#) ]

## [GREATEST](#)

Returns the largest value in a list of expressions of any data type. [ [String functions](#) ]

## [GREATESTB](#)

Returns the largest value in a list of expressions of any data type, using binary ordering. [ [String functions](#) ]

## [GROUP\\_ID](#)

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. [ [Aggregate functions](#) ]

## [GROUPING](#)

Disambiguates the use of NULL values when GROUP BY queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. [ [Aggregate functions](#) ]

## [GROUPING\\_ID](#)

Concatenates the set of Boolean values generated by the GROUPING function into a bit vector. [ [Aggregate functions](#) ]

H

## [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#)

Reports the delegation tokens Vertica will use when accessing Kerberized data in HDFS. [ [Hadoop functions](#) ]

## [HAS\\_ROLE](#)

Checks whether a Vertica user role is granted to the specified user or role, and returns true or false. [ [Privileges and access functions](#) ]

## [HAS\\_TABLE\\_PRIVILEGE](#)

Returns true or false to verify whether a user has the specified privilege on a table. [ [System information functions](#) ]

## [HASH](#)

Calculates a hash value over the function arguments, producing a value in the range  $0 \leq x < 263$ . [ [Mathematical functions](#) ]

## [HASH\\_EXTERNAL\\_TOKEN](#)

Returns a hash of a string token, for use with HADOOP\_IMPERSONATION\_CONFIG\_CHECK. [ [Hadoop functions](#) ]

## [HCATALOGCONNECTOR\\_CONFIG\\_CHECK](#)

Tests the configuration of a Vertica cluster that uses the HCatalog Connector to access Hive data. [ [Hadoop functions](#) ]

## [HDFS\\_CLUSTER\\_CONFIG\\_CHECK](#)

Tests the configuration of a Vertica cluster that uses HDFS. [ [Hadoop functions](#) ]

## [HEX\\_TO\\_BINARY](#)

Translates the given VARCHAR hexadecimal representation into a VARBINARY value. [ [String functions](#) ]

## [HEX\\_TO\\_INTEGER](#)

Translates the given VARCHAR hexadecimal representation into an INTEGER value. [ [String functions](#) ]

## [HOUR](#)

Returns the hour portion of the specified date as an integer, where 0 is 00:00 to 00:59. [ [Date/time functions](#) ]

I

## [IFNULL](#)

Returns the value of the first non-null expression in the list. [ [NULL-handling functions](#) ]

## [IFOREST](#)

Trains and returns an isolation forest (iForest) model. [ [Data preparation](#) ]

## [IMPLODE](#)

Takes a column of any scalar type and returns an unbounded array. [ [Collection functions](#) ]

## [IMPORT\\_DIRECTED\\_QUERIES](#)

Imports to the database catalog directed queries from a SQL file that was generated by EXPORT\_DIRECTED\_QUERIES. [ [Directed queries functions](#) ]

## [IMPORT\\_MODELS](#)

Imports models into Vertica, either Vertica models that were exported with EXPORT\_MODELS, or models in Predictive Model Markup Language (PMML) or TensorFlow format. [ [Model management](#) ]

## [IMPORT\\_STATISTICS](#)

Imports statistics from the XML file that was generated by EXPORT\_STATISTICS. [ [Statistics management functions](#) ]

### **[IMPUTE](#)**

Imputes missing values in a data set with either the mean or the mode, based on observed values for a variable in each column. [ [Data preparation](#) ]

### **[INET\\_ATON](#)**

Converts a string that contains a dotted-quad representation of an IPv4 network address to an INTEGER. [ [IP address functions](#) ]

### **[INET\\_NTOA](#)**

Converts an INTEGER value into a VARCHAR dotted-quad representation of an IPv4 network address. [ [IP address functions](#) ]

### **[INFER\\_EXTERNAL\\_TABLE\\_DDL](#)**

This function is deprecated and will be removed in a future release. [ [Table functions](#) ]

### **[INFER\\_TABLE\\_DDL](#)**

Inspects a file in Parquet, ORC, JSON, or Avro format and returns a CREATE TABLE or CREATE EXTERNAL TABLE statement based on its contents. [ [Table functions](#) ]

### **[INITCAP](#)**

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase. [ [String functions](#) ]

### **[INITCAPB](#)**

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase. [ [String functions](#) ]

### **[INSERT](#)**

Inserts a character string into a specified location in another character string. [ [String functions](#) ]

### **[INSTALL\\_LICENSE](#)**

Installs the license key in the global catalog. [ [Catalog functions](#) ]

### **[INSTR](#)**

Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence. [ [String functions](#) ]

### **[INSTRB](#)**

Searches string for substring and returns an integer indicating the octet position within string that is the first occurrence. [ [String functions](#) ]

### **[INTERRUPT\\_STATEMENT](#)**

Interrupts the specified statement in a user session, rolls back the current transaction, and writes a success or failure message to the log file. [ [Session functions](#) ]

### **[ISFINITE](#)**

Tests for the special TIMESTAMP constant INFINITY and returns a value of type BOOLEAN. [ [Date/time functions](#) ]

### **[ISNULL](#)**

Returns the value of the first non-null expression in the list. [ [NULL-handling functions](#) ]

### **[ISUTF8](#)**

Tests whether a string is a valid UTF-8 string. [ [String functions](#) ]

J

### **[JARO\\_DISTANCE](#)**

Calculates and returns the Jaro similarity, an edit distance between two sequences. [ [String functions](#) ]

### **[JARO\\_WINKLER\\_DISTANCE](#)**

Calculates and returns the Jaro-Winkler similarity, an edit distance between two sequences. [ [String functions](#) ]

### **[JULIAN\\_DAY](#)**

Returns the integer value of the specified day according to the Julian calendar, where day 1 is the first day of the Julian period, January 1, 4713 BC (on the Gregorian calendar, November 24, 4714 BC). [ [Date/time functions](#) ]

K

### **[KERBEROS\\_CONFIG\\_CHECK](#)**

Tests the Kerberos configuration of a Vertica cluster. [ [Database functions](#) ]

### **[KERBEROS\\_HDFS\\_CONFIG\\_CHECK](#)**

This function is deprecated and will be removed in a future release. [ [Hadoop functions](#) ]

### **[KMEANS](#)**

Executes the k-means algorithm on an input relation. [ [Machine learning algorithms](#) ]

### **[KPROTOTYPES](#)**

Executes the k-prototypes algorithm on an input relation. [ [Machine learning algorithms](#) ]

L

### **[LAG \[analytic\]](#)**

Returns the value of the input expression at the given offset before the current row within a. [ [Analytic functions](#) ]

### **[LAST\\_DAY](#)**

Returns the last day of the month in the specified date. [ [Date/time functions](#) ]

### **[LAST\\_INSERT\\_ID](#)**

Returns the last value of an IDENTITY column. [ [Table functions](#) ]

### **[LAST\\_VALUE \[analytic\]](#)**

Lets you select the last value of a table or partition (determined by the window-order-clause) without having to use a self join. [ [Analytic functions](#) ]

### **[LDAP\\_LINK\\_DRYRUN\\_CONNECT](#)**

Takes a set of LDAP Link connection parameters as arguments and begins a dry run connection between the LDAP server and Vertica. [ [LDAP link functions](#) ]

### **[LDAP\\_LINK\\_DRYRUN\\_SEARCH](#)**

Takes a set of LDAP Link connection and search parameters as arguments and begins a dry run search for users and groups that would get imported from the LDAP server. [ [LDAP link functions](#) ]

### **[LDAP\\_LINK\\_DRYRUN\\_SYNC](#)**

Takes a set of LDAP Link connection and search parameters as arguments and begins a dry run synchronization between the database and the LDAP server, which maps and synchronizes the LDAP server's users and groups with their equivalents in Vertica. [ [LDAP link functions](#) ]

### **[LDAP\\_LINK\\_SYNC\\_CANCEL](#)**

Cancels in-progress LDAP Link synchronizations (including those started by LDAP\_LINK\_DRYRUN\_SYNC) between the LDAP server and Vertica. [ [LDAP link functions](#) ]

### **[LDAP\\_LINK\\_SYNC\\_START](#)**

Begins the synchronization between the LDAP and Vertica servers immediately rather than waiting for the next scheduled run set by the parameters LDAPLinkInterval and LDAPLinkCron. [ [LDAP link functions](#) ]

### **[LEAD \[analytic\]](#)**

Returns values from the row after the current row within a , letting you access more than one row in a table at the same time. [ [Analytic functions](#) ]

### **[LEAST](#)**

Returns the smallest value in a list of expressions of any data type. [ [String functions](#) ]

### **[LEASTB](#)**

Returns the smallest value in a list of expressions of any data type, using binary ordering. [ [String functions](#) ]

### **[LEFT](#)**

Returns the specified characters from the left side of a string. [ [String functions](#) ]

### **[LENGTH](#)**

Returns the length of a string. [ [String functions](#) ]

### **[LIFT\\_TABLE](#)**

Returns a table that compares the predictive quality of a machine learning model. [ [Model evaluation](#) ]

### **[LINEAR\\_REG](#)**

Executes linear regression on an input relation, and returns a linear regression model. [ [Machine learning algorithms](#) ]

### **[LIST\\_ENABLED\\_CIPHERS](#)**

Returns a list of enabled cipher suites, which are sets of algorithms used to secure TLS/SSL connections. [ [System information functions](#) ]

### **[LISTAGG](#)**

Transforms non-null values from a group of rows into a list of values that are delimited by commas (default) or a configurable separator. [ [Aggregate functions](#) ]

### **[LN](#)**

Returns the natural logarithm of the argument. [ [Mathematical functions](#) ]

### **[LOCALTIME](#)**

Returns a value of type TIME that represents the start of the current transaction. [ [Date/time functions](#) ]

### **[LOCALTIMESTAMP](#)**

Returns a value of type TIMESTAMP/TIMESTAMPTZ that represents the start of the current transaction, and remains unchanged until the transaction is closed. [ [Date/time functions](#) ]

### **[LOG](#)**

Returns the logarithm to the specified base of the argument. [ [Mathematical functions](#) ]

### **[LOG10](#)**

Returns the base 10 logarithm of the argument, also known as the common logarithm. [ [Mathematical functions](#) ]

### **[LOGISTIC\\_REG](#)**

Executes logistic regression on an input relation. [ [Machine learning algorithms](#) ]

### **[LOWER](#)**

Takes a string value and returns a VARCHAR value converted to lowercase. [ [String functions](#) ]

### **[LOWERB](#)**

Returns a character string with each ASCII character converted to lowercase. [ [String functions](#) ]

### **[LPAD](#)**

Returns a VARCHAR value representing a string of a specific length filled on the left with specific characters. [ [String functions](#) ]

### **[LTRIM](#)**

Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning). [ [String functions](#) ]

## **M**

### **[MAKE\\_AHM\\_NOW](#)**

Sets the (AHM) to the greatest allowable value. [ [Epoch functions](#) ]

### **[MAKEUTF8](#)**

Coerces a string to UTF-8 by removing or replacing non-UTF-8 characters. [ [String functions](#) ]

### **[MAPAGGREGATE](#)**

Returns a LONG VARBINARY VMap with key and value pairs supplied from two VARCHAR input columns. [ [Flex map functions](#) ]

### **[MAPCONTAINSKEY](#)**

Determines whether a VMap contains a virtual column (key). [ [Flex map functions](#) ]

### **[MAPCONTAINSVALUE](#)**

Determines whether a VMap contains a specific value. [ [Flex map functions](#) ]

### **[MAPDELIMITEDEXTRACTOR](#)**

Extracts data with a delimiter character and other optional arguments, returning a single VMap value. [ [Flex extractor functions](#) ]

### **[MAPITEMS](#)**

Returns information about items in a VMap. [ [Flex map functions](#) ]

### **[MAPJSONEXTRACTOR](#)**

Extracts content of repeated JSON data objects,, including nested maps, or data with an outer list of JSON elements. [ [Flex extractor functions](#) ]

### **[MAPKEYS](#)**

Returns the virtual columns (and values) present in any VMap data. [ [Flex map functions](#) ]

### **[MAPKEYSINFO](#)**

Returns virtual column information from a given map. [ [Flex map functions](#) ]

### **[MAPLOOKUP](#)**

Returns single-key values from VMAP data. [ [Flex map functions](#) ]

### **[MAPPUT](#)**

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added. [ [Flex map functions](#) ]

### **[MAPREGEXEXTRACTOR](#)**

Extracts data with a regular expression and returns results as a VMap. [ [Flex extractor functions](#) ]

### **[MAPSIZE](#)**

Returns the number of virtual columns present in any VMap data. [ [Flex map functions](#) ]

### **[MAPTOSTRING](#)**

Recursively builds a string representation of VMap data, including nested JSON maps. [ [Flex map functions](#) ]

### **[MAPVALUES](#)**

Returns a string representation of the top-level values from a VMap. [ [Flex map functions](#) ]

### **[MAPVERSION](#)**

Returns the version or invalidity of any map data. [ [Flex map functions](#) ]

### **[MARK\\_DESIGN\\_KSAFE](#)**

Enables or disables high availability in your environment, in case of a failure. [ [Catalog functions](#) ]

### **[MATCH\\_COLUMNS](#)**

Specified as an element in a SELECT list, returns all columns in queried tables that match the specified pattern. [ [Regular expression functions](#) ]

## **MATCH\_ID**

Returns a successful pattern match as an INTEGER value. [ [MATCH clause functions](#) ]

## **MATERIALIZED\_FLEXTABLE\_COLUMNS**

Materializes virtual columns listed as key\_names in the flextable\_keys table you compute using either COMPUTE\_FLEXTABLE\_KEYS or COMPUTE\_FLEXTABLE\_KEYS\_AND\_BUILD\_VIEW. [ [Flex data functions](#) ]

## **MAX [aggregate]**

Returns the greatest value of an expression over a group of rows. [ [Aggregate functions](#) ]

## **MAX [analytic]**

Returns the maximum value of an expression within a. [ [Analytic functions](#) ]

## **MD5**

Calculates the MD5 hash of string, returning the result as a VARCHAR string in hexadecimal. [ [String functions](#) ]

## **MEASURE\_LOCATION\_PERFORMANCE**

Measures a storage location's disk performance. [ [Storage functions](#) ]

## **MEDIAN [analytic]**

For each row, returns the median value of a value set within each partition. [ [Analytic functions](#) ]

## **MEMORY\_TRIM**

Calls glibc function malloc\_trim() to reclaim free memory from malloc and return it to the operating system. [ [Database functions](#) ]

## **MICROSECOND**

Returns the microsecond portion of the specified date as an integer. [ [Date/time functions](#) ]

## **MIDNIGHT\_SECONDS**

Within the specified date, returns the number of seconds between midnight and the date's time portion. [ [Date/time functions](#) ]

## **MIGRATE\_ENTERPRISE\_TO\_EON**

Migrates an Enterprise database to an Eon Mode database. [ [Eon Mode functions](#) ]

## **MIN [aggregate]**

Returns the smallest value of an expression over a group of rows. [ [Aggregate functions](#) ]

## **MIN [analytic]**

Returns the minimum value of an expression within a. [ [Analytic functions](#) ]

## **MINUTE**

Returns the minute portion of the specified date as an integer. [ [Date/time functions](#) ]

## **MOD**

Returns the remainder of a division operation. [ [Mathematical functions](#) ]

## **MONTH**

Returns the month portion of the specified date as an integer. [ [Date/time functions](#) ]

## **MONTHS\_BETWEEN**

Returns the number of months between two dates. [ [Date/time functions](#) ]

## **MOVE\_PARTITIONS\_TO\_TABLE**

Moves partitions from one table to another. [ [Partition functions](#) ]

## **MOVE\_RETIRED\_LOCATION\_DATA**

Moves all data from the specified retired storage location or from all retired storage locations in the database. [ [Storage functions](#) ]

## **MOVE\_STATEMENT\_TO\_RESOURCE\_POOL**

Attempts to move the specified query to the specified target pool. [ [Workload management functions](#) ]

## **MOVING\_AVERAGE**

Creates a moving-average (MA) model from a stationary time series with consistent timesteps that can then be used for prediction via PREDICT\_MOVING\_AVERAGE. [ [Machine learning algorithms](#) ]

## **MSE**

Returns a table that displays the mean squared error of the prediction and response columns in a machine learning model. [ [Model evaluation](#) ]

## **N**

## **NAIVE\_BAYES**

Executes the Naive Bayes algorithm on an input relation and returns a Naive Bayes model. [ [Machine learning algorithms](#) ]

## **NEW\_TIME**

Converts a timestamp value from one time zone to another and returns a TIMESTAMP. [ [Date/time functions](#) ]

## **NEXT\_DAY**

Returns the date of the first instance of a particular day of the week that follows the specified date. [ [Date/time functions](#) ]

#### **[NEXTVAL](#)**

Returns the next value in a sequence. [ [Sequence functions](#) ]

#### **[NORMALIZE](#)**

Runs a normalization algorithm on an input relation. [ [Data preparation](#) ]

#### **[NORMALIZE\\_FIT](#)**

This function differs from NORMALIZE, which directly outputs a view with normalized results, rather than storing normalization parameters into a model for later operation. [ [Data preparation](#) ]

#### **[NOTIFY](#)**

Sends a specified message to a NOTIFIER. [ [Notifier functions](#) ]

#### **[NOW \[date/time\]](#)**

Returns a value of type TIMESTAMP WITH TIME ZONE representing the start of the current transaction. [ [Date/time functions](#) ]

#### **[NTH\\_VALUE \[analytic\]](#)**

Returns the value evaluated at the row that is the nth row of the window (counting from 1). [ [Analytic functions](#) ]

#### **[NTILE \[analytic\]](#)**

Equally divides an ordered data set (partition) into a {value} number of subsets within a , where the subsets are numbered 1 through the value in parameter constant-value. [ [Analytic functions](#) ]

#### **[NULLIF](#)**

Compares two expressions. [ [NULL-handling functions](#) ]

#### **[NULLIFZERO](#)**

Evaluates to NULL if the value in the column is 0. [ [NULL-handling functions](#) ]

#### **[NVL](#)**

Returns the value of the first non-null expression in the list. [ [NULL-handling functions](#) ]

#### **[NVL2](#)**

Takes three arguments. [ [NULL-handling functions](#) ]

#### **O**

#### **[OCTET\\_LENGTH](#)**

Takes one argument as an input and returns the string length in octets for all string types. [ [String functions](#) ]

#### **[ONE\\_HOT\\_ENCODER\\_FIT](#)**

Generates a sorted list of each of the category levels for each feature to be encoded, and stores the model. [ [Data preparation](#) ]

#### **[OVERLAPS](#)**

Evaluates two time periods and returns true when they overlap, false otherwise. [ [Date/time functions](#) ]

#### **[OVERLAY](#)**

Replaces part of a string with another string and returns the new string value as a VARCHAR. [ [String functions](#) ]

#### **[OVERLAYB](#)**

Replaces part of a string with another string and returns the new string as an octet value. [ [String functions](#) ]

#### **P**

#### **[PARTITION\\_PROJECTION](#)**

Splits containers for a specified projection. [ [Partition functions](#) ]

#### **[PARTITION\\_TABLE](#)**

Invokes the to reorganize ROS storage containers as needed to conform with the current partitioning policy. [ [Partition functions](#) ]

#### **[PATTERN\\_ID](#)**

Returns an integer value that is a partition-wide unique identifier for the instance of the pattern that matched. [ [MATCH clause functions](#) ]

#### **[PCA](#)**

Computes principal components from the input table/view. [ [Data preparation](#) ]

#### **[PERCENT\\_RANK \[analytic\]](#)**

Calculates the relative rank of a row for a given row in a group within a by dividing that row's rank less 1 by the number of rows in the partition, also less 1. [ [Analytic functions](#) ]

#### **[PERCENTILE\\_CONT \[analytic\]](#)**

An inverse distribution function where, for each row, PERCENTILE\_CONT returns the value that would fall into the specified percentile among a set of values in each partition within a. [ [Analytic functions](#) ]

#### **[PERCENTILE\\_DISC \[analytic\]](#)**

An inverse distribution function where, for each row, PERCENTILE\_DISC returns the value that would fall into the specified percentile among a set of values in each partition within a. [ [Analytic functions](#) ]

## **[PI](#)**

Returns the constant pi (P), the ratio of any circle's circumference to its diameter in Euclidean geometry The return type is DOUBLE PRECISION. [ [Mathematical functions](#) ]

## **[PLS\\_REG](#)**

Executes PLS regression on an input relation, and returns a PLS regression model. [ [Machine learning algorithms](#) ]

## **[POISSON\\_REG](#)**

Executes Poisson regression on an input relation, and returns a Poisson regression model. [ [Machine learning algorithms](#) ]

## **[POSITION](#)**

Returns an INTEGER value representing the character location of a specified substring with a string (counting from one). [ [String functions](#) ]

## **[POSITIONB](#)**

Returns an INTEGER value representing the octet location of a specified substring with a string (counting from one). [ [String functions](#) ]

## **[POWER](#)**

Returns a DOUBLE PRECISION value representing one number raised to the power of another number. [ [Mathematical functions](#) ]

## **[PRC](#)**

Returns a table that displays the points on a receiver precision recall (PR) curve. [ [Model evaluation](#) ]

## **[PREDICT\\_ARIMA](#)**

Applies an autoregressive integrated moving average (ARIMA) model to an input relation or makes predictions using the in-sample data. [ [Transformation functions](#) ]

## **[PREDICT\\_AUTOREGRESSOR](#)**

Applies an autoregressor (AR) model to an input relation. [ [Transformation functions](#) ]

## **[PREDICT\\_LINEAR\\_REG](#)**

Applies a linear regression model on an input relation and returns the predicted value as a FLOAT. [ [Transformation functions](#) ]

## **[PREDICT\\_LOGISTIC\\_REG](#)**

Applies a logistic regression model on an input relation. [ [Transformation functions](#) ]

## **[PREDICT\\_MOVING\\_AVERAGE](#)**

Applies a moving-average (MA) model, created by MOVING\_AVERAGE, to an input relation. [ [Transformation functions](#) ]

## **[PREDICT\\_NAIVE\\_BAYES](#)**

Applies a Naive Bayes model on an input relation. [ [Transformation functions](#) ]

## **[PREDICT\\_NAIVE\\_BAYES\\_CLASSES](#)**

Applies a Naive Bayes model on an input relation and returns the probabilities of classes:. [ [Transformation functions](#) ]

## **[PREDICT\\_PLS\\_REG](#)**

Applies a PLS regression model on an input relation and returns the predicted values. [ [Transformation functions](#) ]

## **[PREDICT\\_PMML](#)**

Applies an imported PMML model on an input relation. [ [Transformation functions](#) ]

## **[PREDICT\\_POISSON\\_REG](#)**

Applies a Poisson regression model on an input relation and returns the predicted value as a FLOAT. [ [Transformation functions](#) ]

## **[PREDICT\\_RF\\_CLASSIFIER](#)**

Applies a random forest model on an input relation. [ [Transformation functions](#) ]

## **[PREDICT\\_RF\\_CLASSIFIER\\_CLASSES](#)**

Applies a random forest model on an input relation and returns the probabilities of classes:. [ [Transformation functions](#) ]

## **[PREDICT\\_RF\\_REGRESSOR](#)**

Applies a random forest model on an input relation, and returns with a FLOAT data type that specifies the predicted value of the random forest model—the average of the prediction of the trees in the forest. [ [Transformation functions](#) ]

## **[PREDICT\\_SVM\\_CLASSIFIER](#)**

Uses an SVM model to predict class labels for samples in an input relation, and returns the predicted value as a FLOAT data type. [ [Transformation functions](#) ]

## **[PREDICT\\_SVM\\_REGRESSOR](#)**

Uses an SVM model to perform regression on samples in an input relation, and returns the predicted value as a FLOAT data type. [ [Transformation functions](#) ]

## **[PREDICT\\_TENSORFLOW](#)**

Applies a TensorFlow model on an input relation, and returns with the result expected for the encoded model type. [ [Transformation functions](#) ]

### [PREDICT\\_TENSORFLOW\\_SCALAR](#)

Applies a TensorFlow model on an input relation, and returns with the result expected for the encoded model type. This function supports 1D complex types as input and output. [ [Transformation functions](#) ]

### [PREDICT\\_XGB\\_CLASSIFIER](#)

Applies an XGBoost classifier model on an input relation. [ [Transformation functions](#) ]

### [PREDICT\\_XGB\\_CLASSIFIER\\_CLASSES](#)

Applies an XGBoost classifier model on an input relation and returns the probabilities of classes:. [ [Transformation functions](#) ]

### [PREDICT\\_XGB\\_REGRESSOR](#)

Applies an XGBoost regressor model on an input relation. [ [Transformation functions](#) ]

### [PROMOTE\\_SUBCLUSTER\\_TO\\_PRIMARY](#)

Converts a secondary subcluster to a. [ [Eon Mode functions](#) ]

### [PURGE](#)

Permanently removes delete vectors from ROS storage containers so disk space can be reused. [ [Database functions](#) ]

### [PURGE\\_PARTITION](#)

Purges a table partition of deleted rows. [ [Partition functions](#) ]

### [PURGE\\_PROJECTION](#)

PURGE\_PROJECTION can use significant disk space while purging the data. [ [Projection functions](#) ]

### [PURGE\\_TABLE](#)

This function was formerly named PURGE\_TABLE\_PROJECTIONS(). [ [Table functions](#) ]

## Q

### [QUARTER](#)

Returns calendar quarter of the specified date as an integer, where the January-March quarter is 1. [ [Date/time functions](#) ]

### [QUOTE\\_IDENT](#)

Returns the specified string argument in the format required to use the string as an identifier in an SQL statement. [ [String functions](#) ]

### [QUOTE\\_LITERAL](#)

Returns the given string suitably quoted for use as a string literal in a SQL statement string. [ [String functions](#) ]

### [QUOTE\\_NULLABLE](#)

Returns the given string suitably quoted for use as a string literal in an SQL statement string; or if the argument is null, returns the unquoted string NULL. [ [String functions](#) ]

## R

### [RADIANS](#)

Returns a DOUBLE PRECISION value representing an angle expressed in radians. [ [Mathematical functions](#) ]

### [RANDOM](#)

Returns a uniformly-distributed random DOUBLE PRECISION value  $x$ , where  $0 \leq x < 1$ . [ [Mathematical functions](#) ]

### [RANDOMINT](#)

Accepts and returns an integer between 0 and the integer argument expression-1. [ [Mathematical functions](#) ]

### [RANDOMINT\\_CRYPTO](#)

Accepts and returns an INTEGER value from a set of values between 0 and the specified function argument -1. [ [Mathematical functions](#) ]

### [RANK \[analytic\]](#)

Within each window partition, ranks all rows in the query results set according to the order specified by the window's ORDER BY clause. [ [Analytic functions](#) ]

### [READ\\_CONFIG\\_FILE](#)

Reads and returns the key-value pairs of all the parameters of a given tokenizer. [ [Text search functions](#) ]

### [READ\\_TREE](#)

Reads the contents of trees within the random forest or XGBoost model. [ [Model evaluation](#) ]

### [REALIGN\\_CONTROL\\_NODES](#)

Causes Vertica to re-evaluate which nodes in the cluster or subcluster are and which nodes are assigned to them as dependents when large cluster is enabled. [ [Cluster functions](#) ]

### [REBALANCE\\_CLUSTER](#)

Rebalances the database cluster synchronously as a session foreground task. [ [Cluster functions](#) ]

### [REBALANCE\\_SHARDS](#)

Rebalances shard assignments in a subcluster or across the entire cluster in Eon Mode. [ [Eon Mode functions](#) ]

## **[REBALANCE TABLE](#)**

Synchronously rebalances data in the specified table. [ [Table functions](#) ]

## **[REENABLE\\_DUPLICATE\\_KEY\\_ERROR](#)**

Restores the default behavior of error reporting by reversing the effects of DISABLE\_DUPLICATE\_KEY\_ERROR. [ [Table functions](#) ]

## **[REFRESH](#)**

Synchronously refreshes one or more table projections in the foreground, and updates the PROJECTION\_REFRESHES system table. [ [Projection functions](#) ]

## **[REFRESH\\_COLUMNS](#)**

Refreshes table columns that are defined with the constraint SET USING or DEFAULT USING. [ [Projection functions](#) ]

## **[REGEXP\\_COUNT](#)**

Returns the number times a regular expression matches a string. [ [Regular expression functions](#) ]

## **[REGEXP\\_ILIKE](#)**

Returns true if the string contains a match for the regular expression. [ [Regular expression functions](#) ]

## **[REGEXP\\_INSTR](#)**

Returns the starting or ending position in a string where a regular expression matches. [ [Regular expression functions](#) ]

## **[REGEXP\\_LIKE](#)**

Returns true if the string matches the regular expression. [ [Regular expression functions](#) ]

## **[REGEXP\\_NOT\\_ILIKE](#)**

Returns true if the string does not match the case-insensitive regular expression. [ [Regular expression functions](#) ]

## **[REGEXP\\_NOT\\_LIKE](#)**

Returns true if the string does not contain a match for the regular expression. [ [Regular expression functions](#) ]

## **[REGEXP\\_REPLACE](#)**

Replaces all occurrences of a substring that match a regular expression with another substring. [ [Regular expression functions](#) ]

## **[REGEXP\\_SUBSTR](#)**

Returns the substring that matches a regular expression within a string. [ [Regular expression functions](#) ]

## **[REGISTER\\_MODEL](#)**

Registers a trained model and adds it to Model Versioning environment with a status of 'under\_review'. [ [Model management](#) ]

## **[REGR\\_AVGX](#)**

Returns the DOUBLE PRECISION average of the independent expression in an expression pair. [ [Aggregate functions](#) ]

## **[REGR\\_AVGY](#)**

Returns the DOUBLE PRECISION average of the dependent expression in an expression pair. [ [Aggregate functions](#) ]

## **[REGR\\_COUNT](#)**

Returns the count of all rows in an expression pair. [ [Aggregate functions](#) ]

## **[REGR\\_INTERCEPT](#)**

Returns the y-intercept of the regression line determined by a set of expression pairs. [ [Aggregate functions](#) ]

## **[REGR\\_R2](#)**

Returns the square of the correlation coefficient of a set of expression pairs. [ [Aggregate functions](#) ]

## **[REGR\\_SLOPE](#)**

Returns the slope of the regression line, determined by a set of expression pairs. [ [Aggregate functions](#) ]

## **[REGR\\_SXX](#)**

Returns the sum of squares of the difference between the independent expression (expression2) and its average. [ [Aggregate functions](#) ]

## **[REGR\\_SXY](#)**

Returns the sum of products of the difference between the dependent expression (expression1) and its average and the difference between the independent expression (expression2) and its average. [ [Aggregate functions](#) ]

## **[REGR\\_SYY](#)**

Returns the sum of squares of the difference between the dependent expression (expression1) and its average. [ [Aggregate functions](#) ]

## **[RELEASE\\_ALL\\_JVM\\_MEMORY](#)**

Forces all sessions to release the memory consumed by their Java Virtual Machines (JVM). [ [Session functions](#) ]

## **[RELEASE\\_JVM\\_MEMORY](#)**

Terminates a Java Virtual Machine (JVM), making available the memory the JVM was using. [ [Session functions](#) ]

## **[RELEASE\\_SYSTEM\\_TABLES\\_ACCESS](#)**

Enables non-superuser access to all system tables. [ [Privileges and access functions](#) ]

## **[RELOAD\\_ADMINTOOLS\\_CONF](#)**

Updates the admintools.conf on each UP node in the cluster. [ [Catalog functions](#) ]

## **[RELOAD\\_SPREAD](#)**

Updates cluster changes to the catalog's Spread configuration file. [ [Cluster functions](#) ]

## **[REPEAT](#)**

Replicates a string the specified number of times and concatenates the replicated values as a single string. [ [String functions](#) ]

## **[REPLACE](#)**

Replaces all occurrences of characters in a string with another set of characters. [ [String functions](#) ]

## **[RESERVE\\_SESSION\\_RESOURCE](#)**

Reserves memory resources from the general resource pool for the exclusive use of the Vertica backup and restore process. [ [Session functions](#) ]

## **[RESET\\_LOAD\\_BALANCE\\_POLICY](#)**

Resets the counter each host in the cluster maintains, to track which host it will refer a client to when the native connection load balancing scheme is set to ROUNDROBIN. [ [Client connection functions](#) ]

## **[RESET\\_SESSION](#)**

Applies your default connection string configuration settings to your current session. [ [Session functions](#) ]

## **[RESHARD\\_DATABASE](#)**

Changes the number of shards in a database. [ [Eon Mode functions](#) ]

## **[RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)**

Restores the keys table and the view. [ [Flex data functions](#) ]

## **[RESTORE\\_LOCATION](#)**

Restores a storage location that was previously retired with RETIRE\_LOCATION. [ [Storage functions](#) ]

## **[RESTRICT\\_SYSTEM\\_TABLES\\_ACCESS](#)**

Checks system table SYSTEM\_TABLES to determine which system tables non-superusers can access. [ [Privileges and access functions](#) ]

## **[RETIRE\\_LOCATION](#)**

Deactivates the specified storage location. [ [Storage functions](#) ]

## **[REVERSE\\_NORMALIZE](#)**

Reverses the normalization transformation on normalized data, thereby de-normalizing the normalized data. [ [Transformation functions](#) ]

## **[RF\\_CLASSIFIER](#)**

Trains a random forest model for classification on an input relation. [ [Machine learning algorithms](#) ]

## **[RF\\_PREDICTOR\\_IMPORTANCE](#)**

Measures the importance of the predictors in a random forest model using the Mean Decrease Impurity (MDI) approach. [ [Model evaluation](#) ]

## **[RF\\_REGRESSOR](#)**

Trains a random forest model for regression on an input relation. [ [Machine learning algorithms](#) ]

## **[RIGHT](#)**

Returns the specified characters from the right side of a string. [ [String functions](#) ]

## **[ROC](#)**

Returns a table that displays the points on a receiver operating characteristic curve. [ [Model evaluation](#) ]

## **[ROUND](#)**

Rounds the specified date or time. [ [Date/time functions](#) ]

## **[ROUND](#)**

Rounds a value to a specified number of decimal places, retaining the original precision and scale. [ [Mathematical functions](#) ]

## **[ROW\\_NUMBER \[analytic\]](#)**

Assigns a sequence of unique numbers to each row in a partition, starting with 1. [ [Analytic functions](#) ]

## **[RPAD](#)**

Returns a VARCHAR value representing a string of a specific length filled on the right with specific characters. [ [String functions](#) ]

## **[RSQUARED](#)**

Returns a table with the R-squared value of the predictions in a regression model. [ [Model evaluation](#) ]

## **[RTRIM](#)**

Returns a VARCHAR value representing a string with trailing blanks removed from the right side (end). [ [String functions](#) ]

## **[RUN\\_INDEX\\_TOOL](#)**

Runs the Index tool on a Vertica database to perform one of these tasks:. [ [Database functions](#) ]

**[SANDBOX\\_SUBCLUSTER](#)**

Creates a sandbox for a secondary subcluster. [ [Eon Mode functions](#) ]

**[SAVE\\_PLANS](#)**

Creates optimizer-generated directed queries from the most frequently executed queries, up to the maximum specified. [ [Directed queries functions](#) ]

**[SECOND](#)**

Returns the seconds portion of the specified date as an integer. [ [Date/time functions](#) ]

**[SECURITY\\_CONFIG\\_CHECK](#)**

Returns the status of various security-related parameters. [ [Database functions](#) ]

**[SESSION\\_USER](#)**

Returns a VARCHAR containing the name of the user who initiated the current database session. [ [System information functions](#) ]

**[SET\\_AHM\\_EPOCH](#)**

Sets the (AHM) to the specified epoch. [ [Epoch functions](#) ]

**[SET\\_AHM\\_TIME](#)**

Sets the (AHM) to the epoch corresponding to the specified time on the initiator node. [ [Epoch functions](#) ]

**[SET\\_AUDIT\\_TIME](#)**

Sets the time that Vertica performs automatic database size audit to determine if the size of the database is compliant with the raw data allowance in your Vertica license. [ [License functions](#) ]

**[SET\\_CLIENT\\_LABEL](#)**

Assigns a label to a client connection for the current session. [ [Client connection functions](#) ]

**[SET\\_CONFIG\\_PARAMETER](#)**

Sets or clears a configuration parameter at the specified level. [ [Database functions](#) ]

**[SET\\_CONTROL\\_SET\\_SIZE](#)**

Sets the number of that participate in the spread service when large cluster is enabled. [ [Cluster functions](#) ]

**[SET\\_DATA\\_COLLECTOR\\_NOTIFY\\_POLICY](#)**

Creates/enables notification policies for a component. [ [Notifier functions](#) ]

**[SET\\_DATA\\_COLLECTOR\\_POLICY](#)**

Updates the following retention policy properties for the specified component:. [ [Data Collector functions](#) ]

**[SET\\_DATA\\_COLLECTOR\\_POLICY \(using parameters\)](#)**

Updates selected retention policy properties for a component. [ [Data Collector functions](#) ]

**[SET\\_DATA\\_COLLECTOR\\_TIME\\_POLICY](#)**

Updates the retention policy property INTERVAL\_TIME for the specified component. [ [Data Collector functions](#) ]

**[SET\\_DEPOT\\_ANTI\\_PIN\\_POLICY\\_PARTITION](#)**

Assigns the highest depot eviction priority to a partition. [ [Eon Mode functions](#) ]

**[SET\\_DEPOT\\_ANTI\\_PIN\\_POLICY\\_PROJECTION](#)**

Assigns the highest depot eviction priority to a projection. [ [Eon Mode functions](#) ]

**[SET\\_DEPOT\\_ANTI\\_PIN\\_POLICY\\_TABLE](#)**

Assigns the highest depot eviction priority to a table. [ [Eon Mode functions](#) ]

**[SET\\_DEPOT\\_PIN\\_POLICY\\_PARTITION](#)**

Pins the specified partitions of a table or projection to a subcluster depot, or all database depots, to reduce exposure to depot eviction. [ [Eon Mode functions](#) ]

**[SET\\_DEPOT\\_PIN\\_POLICY\\_PROJECTION](#)**

Pins a projection to a subcluster depot, or all database depots, to reduce its exposure to depot eviction. [ [Eon Mode functions](#) ]

**[SET\\_DEPOT\\_PIN\\_POLICY\\_TABLE](#)**

Pins a table to a subcluster depot, or all database depots, to reduce its exposure to depot eviction. [ [Eon Mode functions](#) ]

**[SET\\_LOAD\\_BALANCE\\_POLICY](#)**

Sets how native connection load balancing chooses a host to handle a client connection. [ [Client connection functions](#) ]

**[SET\\_LOCATION\\_PERFORMANCE](#)**

Sets disk performance for a storage location. [ [Storage functions](#) ]

**[SET\\_OBJECT\\_STORAGE\\_POLICY](#)**

Creates or changes the storage policy of a database object by assigning it a labeled storage location. [ [Storage functions](#) ]

## **[SET\\_SCALING\\_FACTOR](#)**

Sets the scaling factor that determines the number of storage containers used when rebalancing the database and when using local data segmentation is enabled. [ [Cluster functions](#) ]

## **[SET\\_SPREAD\\_OPTION](#)**

Changes daemon settings. [ [Database functions](#) ]

## **[SET\\_TOKENIZER\\_PARAMETER](#)**

Configures the tokenizer parameters. [ [Text search functions](#) ]

## **[SET\\_UNION](#)**

Returns a SET containing all elements of two input sets. [ [Collection functions](#) ]

## **[SHA1](#)**

Uses the US Secure Hash Algorithm 1 to calculate the SHA1 hash of string. [ [String functions](#) ]

## **[SHA224](#)**

Uses the US Secure Hash Algorithm 2 to calculate the SHA224 hash of string. [ [String functions](#) ]

## **[SHA256](#)**

Uses the US Secure Hash Algorithm 2 to calculate the SHA256 hash of string. [ [String functions](#) ]

## **[SHA384](#)**

Uses the US Secure Hash Algorithm 2 to calculate the SHA384 hash of string. [ [String functions](#) ]

## **[SHA512](#)**

Uses the US Secure Hash Algorithm 2 to calculate the SHA512 hash of string. [ [String functions](#) ]

## **[SHOW\\_PROFILING\\_CONFIG](#)**

Shows whether profiling is enabled. [ [Profiling functions](#) ]

## **[SHUTDOWN](#)**

Shuts down a Vertica database. [ [Database functions](#) ]

## **[SHUTDOWN\\_SUBCLUSTER](#)**

Shuts down a subcluster. [ [Eon Mode functions](#) ]

## **[SHUTDOWN\\_WITH\\_DRAIN](#)**

Gracefully shuts down a subcluster or subclusters. [ [Eon Mode functions](#) ]

## **[SIGN](#)**

Returns a DOUBLE PRECISION value of -1, 0, or 1 representing the arithmetic sign of the argument. [ [Mathematical functions](#) ]

## **[SIN](#)**

Returns a DOUBLE PRECISION value that represents the trigonometric sine of the passed parameter. [ [Mathematical functions](#) ]

## **[SINH](#)**

Returns a DOUBLE PRECISION value that represents the hyperbolic sine of the passed parameter. [ [Mathematical functions](#) ]

## **[SLEEP](#)**

Waits a specified number of seconds before executing another statement or command. [ [Workload management functions](#) ]

## **[SOUNDEX](#)**

Takes a VARCHAR argument and returns a four-character code that enables comparison of that argument with other SOUNDEX-encoded strings that are spelled differently in English, but are phonetically similar. [ [String functions](#) ]

## **[SOUNDEX\\_MATCHES](#)**

Compares the Soundex encodings of two strings. [ [String functions](#) ]

## **[SPACE](#)**

Returns the specified number of blank spaces, typically for insertion into a character string. [ [String functions](#) ]

## **[SPLIT\\_PART](#)**

Splits string on the delimiter and returns the string at the location of the beginning of the specified field (counting from 1). [ [String functions](#) ]

## **[SPLIT\\_PARTB](#)**

Divides an input string on a delimiter character and returns the Nth segment, counting from 1. [ [String functions](#) ]

## **[SQRT](#)**

Returns a DOUBLE PRECISION value representing the arithmetic square root of the argument. [ [Mathematical functions](#) ]

## **[ST\\_Area](#)**

Calculates the area of a spatial object. [ [Geospatial functions](#) ]

## **[ST\\_AsBinary](#)**

Creates the Well-Known Binary (WKB) representation of a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_AsText](#)**

Creates the Well-Known Text (WKT) representation of a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_Boundary](#)**

Calculates the boundary of the specified GEOMETRY object. [ [Geospatial functions](#) ]

### **[ST\\_Buffer](#)**

Creates a GEOMETRY object greater than or equal to a specified distance from the boundary of a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_Centroid](#)**

Calculates the geometric center—the centroid—of a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_Contains](#)**

Determines if a spatial object is entirely inside another spatial object without existing only on its boundary. [ [Geospatial functions](#) ]

### **[ST\\_ConvexHull](#)**

Calculates the smallest convex GEOMETRY object that contains a GEOMETRY object. [ [Geospatial functions](#) ]

### **[ST\\_Crosses](#)**

Determines if one GEOMETRY object spatially crosses another GEOMETRY object. [ [Geospatial functions](#) ]

### **[ST\\_Difference](#)**

Calculates the part of a spatial object that does not intersect with another spatial object. [ [Geospatial functions](#) ]

### **[ST\\_Disjoint](#)**

Determines if two GEOMETRY objects do not intersect or touch. [ [Geospatial functions](#) ]

### **[ST\\_Distance](#)**

Calculates the shortest distance between two spatial objects. [ [Geospatial functions](#) ]

### **[ST\\_Envelope](#)**

Calculates the minimum bounding rectangle that contains the specified GEOMETRY object. [ [Geospatial functions](#) ]

### **[ST\\_Equals](#)**

Determines if two spatial objects are spatially equivalent. [ [Geospatial functions](#) ]

### **[ST\\_GeographyFromText](#)**

Converts a Well-Known Text (WKT) string into its corresponding GEOGRAPHY object. [ [Geospatial functions](#) ]

### **[ST\\_GeographyFromWKB](#)**

Converts a Well-Known Binary (WKB) value into its corresponding GEOGRAPHY object. [ [Geospatial functions](#) ]

### **[ST\\_GeoHash](#)**

Returns a GeoHash in the shape of the specified geometry. [ [Geospatial functions](#) ]

### **[ST\\_GeometryN](#)**

Returns the n geometry within a geometry object. [ [Geospatial functions](#) ]

### **[ST\\_GeometryType](#)**

Determines the class of a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_GeomFromGeoHash](#)**

Returns a polygon in the shape of the specified GeoHash. [ [Geospatial functions](#) ]

### **[ST\\_GeomFromGeoJSON](#)**

Converts the geometry portion of a GeoJSON record in the standard format into a GEOMETRY object. [ [Geospatial functions](#) ]

### **[ST\\_GeomFromText](#)**

Converts a Well-Known Text (WKT) string into its corresponding GEOMETRY object. [ [Geospatial functions](#) ]

### **[ST\\_GeomFromWKB](#)**

Converts the Well-Known Binary (WKB) value to its corresponding GEOMETRY object. [ [Geospatial functions](#) ]

### **[ST\\_Intersection](#)**

Calculates the set of points shared by two GEOMETRY objects. [ [Geospatial functions](#) ]

### **[ST\\_Intersects](#)**

Determines if two GEOMETRY or GEOGRAPHY objects intersect or touch at a single point. [ [Geospatial functions](#) ]

### **[ST\\_IsEmpty](#)**

Determines if a spatial object represents the empty set. [ [Geospatial functions](#) ]

### **[ST\\_IsSimple](#)**

Determines if a spatial object does not intersect itself or touch its own boundary at any point. [ [Geospatial functions](#) ]

### **[ST\\_IsValid](#)**

Determines if a spatial object is well formed or valid. [ [Geospatial functions](#) ]

### **[ST\\_Length](#)**

Calculates the length of a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_NumGeometries](#)**

Returns the number of geometries contained within a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_NumPoints](#)**

Calculates the number of vertices of a spatial object, empty objects return NULL. [ [Geospatial functions](#) ]

### **[ST\\_Overlaps](#)**

Determines if a GEOMETRY object shares space with another GEOMETRY object, but is not completely contained within that object. [ [Geospatial functions](#) ]

### **[ST\\_PointFromGeoHash](#)**

Returns the center point of the specified GeoHash. [ [Geospatial functions](#) ]

### **[ST\\_PointN](#)**

Finds the n point of a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_Relate](#)**

Determines if a given GEOMETRY object is spatially related to another GEOMETRY object, based on the specified DE-9IM pattern matrix string. [ [Geospatial functions](#) ]

### **[ST\\_SRID](#)**

Identifies the spatial reference system identifier (SRID) stored with a spatial object. [ [Geospatial functions](#) ]

### **[ST\\_SymDifference](#)**

Calculates all the points in two GEOMETRY objects except for the points they have in common, but including the boundaries of both objects. [ [Geospatial functions](#) ]

### **[ST\\_Touches](#)**

Determines if two GEOMETRY objects touch at a single point or along a boundary, but do not have interiors that intersect. [ [Geospatial functions](#) ]

### **[ST\\_Transform](#)**

Returns a new GEOMETRY with its coordinates converted to the spatial reference system identifier (SRID) used by the srid argument. [ [Geospatial functions](#) ]

### **[ST\\_Union](#)**

Calculates the union of all points in two spatial objects. [ [Geospatial functions](#) ]

### **[ST\\_Within](#)**

If spatial object g1 is completely inside of spatial object g2, then ST\_Within returns true. [ [Geospatial functions](#) ]

### **[ST\\_X](#)**

Determines the x- coordinate for a GEOMETRY point or the longitude value for a GEOGRAPHY point. [ [Geospatial functions](#) ]

### **[ST\\_XMax](#)**

Returns the maximum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [ [Geospatial functions](#) ]

### **[ST\\_XMin](#)**

Returns the minimum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [ [Geospatial functions](#) ]

### **[ST\\_Y](#)**

Determines the y-coordinate for a GEOMETRY point or the latitude value for a GEOGRAPHY point. [ [Geospatial functions](#) ]

### **[ST\\_YMax](#)**

Returns the maximum y-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [ [Geospatial functions](#) ]

### **[ST\\_YMin](#)**

Returns the minimum y-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object. [ [Geospatial functions](#) ]

### **[START\\_DRAIN\\_SUBCLUSTER](#)**

Drains a subcluster or subclusters. [ [Eon Mode functions](#) ]

### **[START\\_REAPING\\_FILES](#)**

Starts the disk file deletion in the background as an asynchronous function. [ [Eon Mode functions](#) ]

### **[START\\_REBALANCE\\_CLUSTER](#)**

Asynchronously rebalances the database cluster as a background task. [ [Cluster functions](#) ]

### **[START\\_REFRESH](#)**

Refreshes projections in the current schema with the latest data of their respective. [ [Projection functions](#) ]

### **[STATEMENT\\_TIMESTAMP](#)**

Similar to TRANSACTION\_TIMESTAMP, returns a value of type TIMESTAMP WITH TIME ZONE that represents the start of the current statement. [

[Date/time functions](#).]

### **[STDDEV \[aggregate\]](#)**

Evaluates the statistical sample standard deviation for each member of the group. [[Aggregate functions](#).]

### **[STDDEV \[analytic\]](#)**

Computes the statistical sample standard deviation of the current row with respect to the group within a. [[Analytic functions](#).]

### **[STDDEV\\_POP \[aggregate\]](#)**

Evaluates the statistical population standard deviation for each member of the group. [[Aggregate functions](#).]

### **[STDDEV\\_POP \[analytic\]](#)**

Evaluates the statistical population standard deviation for each member of the group. [[Analytic functions](#).]

### **[STDDEV\\_SAMP \[aggregate\]](#)**

Evaluates the statistical sample standard deviation for each member of the group. [[Aggregate functions](#).]

### **[STDDEV\\_SAMP \[analytic\]](#)**

Computes the statistical sample standard deviation of the current row with respect to the group within a. [[Analytic functions](#).]

### **[STRING\\_TO\\_ARRAY](#)**

Splits a string containing array values and returns a native one-dimensional array. [[Collection functions](#).]

### **[STRPOS](#)**

Returns an INTEGER value that represents the location of a specified substring within a string (counting from one). [[String functions](#).]

### **[STRPOSB](#)**

Returns an INTEGER value representing the location of a specified substring within a string, counting from one, where each octet in the string is counted (as opposed to characters). [[String functions](#).]

### **[STV\\_AsGeoJSON](#)**

Returns the geometry or geography argument as a Geometry Javascript Object Notation (GeoJSON) object. [[Geospatial functions](#).]

### **[STV\\_Create\\_Index](#)**

Creates a spatial index on a set of polygons to speed up spatial intersection with a set of points. [[Geospatial functions](#).]

### **[STV\\_Describe\\_Index](#)**

Retrieves information about an index that contains a set of polygons. [[Geospatial functions](#).]

### **[STV\\_Drop\\_Index](#)**

Deletes a spatial index. [[Geospatial functions](#).]

### **[STV\\_DWithin](#)**

Determines if the shortest distance from the boundary of one spatial object to the boundary of another object is within a specified distance. [[Geospatial functions](#).]

### **[STV\\_Export2Shapefile](#)**

Exports GEOGRAPHY or GEOMETRY data from a database table or a subquery to a shapefile. [[Geospatial functions](#).]

### **[STV\\_Extent](#)**

Returns a bounding box containing all of the input data. [[Geospatial functions](#).]

### **[STV\\_ForceLHR](#)**

Alters the order of the vertices of a spatial object to follow the left-hand-rule. [[Geospatial functions](#).]

### **[STV\\_Geography](#)**

Casts a GEOMETRY object into a GEOGRAPHY object. [[Geospatial functions](#).]

### **[STV\\_GeographyPoint](#)**

Returns a GEOGRAPHY point based on the input values. [[Geospatial functions](#).]

### **[STV\\_Geometry](#)**

Casts a GEOGRAPHY object into a GEOMETRY object. [[Geospatial functions](#).]

### **[STV\\_GeometryPoint](#)**

Returns a GEOMETRY point, based on the input values. [[Geospatial functions](#).]

### **[STV\\_GetExportShapefileDirectory](#)**

Returns the path of the export directory. [[Geospatial functions](#).]

### **[STV\\_Intersect scalar function](#)**

Spatially intersects a point or points with a set of polygons. [[Geospatial functions](#).]

### **[STV\\_Intersect transform function](#)**

Spatially intersects points and polygons. [[Geospatial functions](#).]

### **[STV\\_IsValidReason](#)**

Determines if a spatial object is well formed or valid. [ [Geospatial functions](#) ]

### **[STV\\_LineStringPoint](#)**

Retrieves the vertices of a linestring or multilinestring. [ [Geospatial functions](#) ]

### **[STV\\_MemSize](#)**

Returns the length of the spatial object in bytes as an INTEGER. [ [Geospatial functions](#) ]

### **[STV\\_NN](#)**

Calculates the distance of spatial objects from a reference object and returns (object, distance) pairs in ascending order by distance from the reference object. [ [Geospatial functions](#) ]

### **[STV\\_PolygonPoint](#)**

Retrieves the vertices of a polygon as individual points. [ [Geospatial functions](#) ]

### **[STV\\_Refresh\\_Index](#)**

Appends newly added or updated polygons and removes deleted polygons from an existing spatial index. [ [Geospatial functions](#) ]

### **[STV\\_Rename\\_Index](#)**

Renames a spatial index. [ [Geospatial functions](#) ]

### **[STV\\_Reverse](#)**

Reverses the order of the vertices of a spatial object. [ [Geospatial functions](#) ]

### **[STV\\_SetExportShapefileDirectory](#)**

Specifies the directory to export GEOMETRY or GEOGRAPHY data to a shapefile. [ [Geospatial functions](#) ]

### **[STV\\_ShpCreateTable](#)**

Returns a CREATE TABLE statement with the columns and types of the attributes found in the specified shapefile. [ [Geospatial functions](#) ]

### **[STV\\_ShpSource and STV\\_ShpParser](#)**

These two functions work with COPY to parse and load geometries and attributes from a shapefile into a Vertica table, and convert them to the appropriate GEOMETRY data type. [ [Geospatial functions](#) ]

### **[SUBSTR](#)**

Returns VARCHAR or VARBINARY value representing a substring of a specified string. [ [String functions](#) ]

### **[SUBSTRB](#)**

Returns an octet value representing the substring of a specified string. [ [String functions](#) ]

### **[SUBSTRING](#)**

Returns a value representing a substring of the specified string at the given position, given a value, a position, and an optional length. [ [String functions](#) ]

### **[SUM \[aggregate\]](#)**

Computes the sum of an expression over a group of rows. [ [Aggregate functions](#) ]

### **[SUM \[analytic\]](#)**

Computes the sum of an expression over a group of rows within a. [ [Analytic functions](#) ]

### **[SUM\\_FLOAT \[aggregate\]](#)**

Computes the sum of an expression over a group of rows and returns a DOUBLE PRECISION value. [ [Aggregate functions](#) ]

### **[SUMMARIZE\\_CATCOL](#)**

Returns a statistical summary of categorical data input, in three columns:. [ [Data preparation](#) ]

### **[SUMMARIZE\\_NUMCOL](#)**

Returns a statistical summary of columns in a Vertica table:. [ [Data preparation](#) ]

### **[SVD](#)**

Computes singular values (the diagonal of the S matrix) and right singular vectors (the V matrix) of an SVD decomposition of the input relation. [ [Data preparation](#) ]

### **[SVM\\_CLASSIFIER](#)**

Trains the SVM model on an input relation. [ [Machine learning algorithms](#) ]

### **[SVM\\_REGRESSOR](#)**

Trains the SVM model on an input relation. [ [Machine learning algorithms](#) ]

### **[SWAP\\_PARTITIONS\\_BETWEEN\\_TABLES](#)**

Swaps partitions between two tables. [ [Partition functions](#) ]

### **[SYNC\\_CATALOG](#)**

Synchronizes the catalog to communal storage to enable reviving the current catalog version in the case of an imminent crash. [ [Eon Mode functions](#) ]

### **[SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#)**

Copies the structure of a Hive database schema available through the HCatalog Connector to a Vertica schema. [ [Hadoop functions](#) ]

### **[SYNC\\_WITH\\_HCATALOG\\_SCHEMA\\_TABLE](#)**

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a Vertica table. [ [Hadoop functions](#) ]

### **[SYSDATE](#)**

Returns the current statement's start date and time as a `TIMESTAMP` value. [ [Date/time functions](#) ]

T

### **[TAN](#)**

Returns a `DOUBLE PRECISION` value that represents the trigonometric tangent of the passed parameter. [ [Mathematical functions](#) ]

### **[TANH](#)**

Returns a `DOUBLE PRECISION` value that represents the hyperbolic tangent of the passed parameter. [ [Mathematical functions](#) ]

### **[Template patterns for date/time formatting](#)**

In an output template string (for `TO_CHAR`), certain patterns are recognized and replaced with appropriately formatted data from the value to format. [ [Formatting functions](#) ]

### **[Template patterns for numeric formatting](#)**

A sign formatted using `SG`, `PL`, or `MI` is not anchored to the number. [ [Formatting functions](#) ]

### **[THROW\\_ERROR](#)**

Returns a user-defined error message. [ [Error-handling functions](#) ]

### **[TIME\\_SLICE](#)**

Aggregates data by different fixed-time intervals and returns a rounded-up input `TIMESTAMP` value to a value that corresponds with the start or end of the time slice interval. [ [Date/time functions](#) ]

### **[TIMEOFDAY](#)**

Returns the wall-clock time as a text string. [ [Date/time functions](#) ]

### **[TIMESTAMP\\_ROUND](#)**

Rounds the specified `TIMESTAMP`. [ [Date/time functions](#) ]

### **[TIMESTAMP\\_TRUNC](#)**

Truncates the specified `TIMESTAMP`. [ [Date/time functions](#) ]

### **[TIMESTAMPADD](#)**

Adds the specified number of intervals to a `TIMESTAMP` or `TIMESTAMPTZ` value and returns a result of the same data type. [ [Date/time functions](#) ]

### **[TIMESTAMPDIFF](#)**

Returns the time span between two `TIMESTAMP` or `TIMESTAMPTZ` values, in the intervals specified. [ [Date/time functions](#) ]

### **[TO\\_BITSTRING](#)**

This topic is shared in two locations: [Formatting Functions](#) and [String Functions](#). [ [Formatting functions](#) ]

### **[TO\\_CHAR](#)**

Converts date/time and numeric values into text strings. [ [Formatting functions](#) ]

### **[TO\\_DATE](#)**

This topic shared in two places: [Date/Time functions](#) and [Formatting Functions](#). [ [Formatting functions](#) ]

### **[TO\\_HEX](#)**

This topic is shared in two locations: [Formatting Functions](#) and [String Functions](#). [ [Formatting functions](#) ]

### **[TO\\_JSON](#)**

Returns the JSON representation of a complex-type argument, including mixed and nested complex types. [ [Collection functions](#) ]

### **[TO\\_NUMBER](#)**

Converts a string value to `DOUBLE PRECISION`. [ [Formatting functions](#) ]

### **[TO\\_TIMESTAMP](#)**

Converts a string value or a UNIX/POSIX epoch value to a `TIMESTAMP` type. [ [Formatting functions](#) ]

### **[TO\\_TIMESTAMP\\_TZ](#)**

Converts a string value or a UNIX/POSIX epoch value to a `TIMESTAMP WITH TIME ZONE` type. [ [Formatting functions](#) ]

### **[TRANSACTION\\_TIMESTAMP](#)**

Returns a value of type `TIME WITH TIMEZONE` that represents the start of the current transaction. [ [Date/time functions](#) ]

### **[TRANSLATE](#)**

Replaces individual characters in `string_to_replace` with other characters. [ [String functions](#) ]

## **[TRIM](#)**

Combines the BTRIM, LTRIM, and RTRIM functions into a single function. [ [String functions](#) ]

## **[TRUNC](#)**

Truncates the specified date or time. [ [Date/time functions](#) ]

## **[TRUNC](#)**

Returns the expression value fully truncated (toward zero). [ [Mathematical functions](#) ]

## **[TS\\_FIRST\\_VALUE](#)**

Processes the data that belongs to each time slice. [ [Aggregate functions](#) ]

## **[TS\\_LAST\\_VALUE](#)**

Processes the data that belongs to each time slice. [ [Aggregate functions](#) ]

## **U**

### **[UNNEST](#)**

Expands the elements of one or more collection columns (ARRAY or SET) into individual rows. [ [Collection functions](#) ]

### **[UNSANDBOX\\_SUBCLUSTER](#)**

Removes a subcluster from a sandbox. [ [Eon Mode functions](#) ]

### **[UPGRADE\\_MODEL](#)**

Upgrades a model from a previous Vertica version. [ [Model management](#) ]

### **[UPPER](#)**

Returns a VARCHAR value containing the argument converted to uppercase letters. [ [String functions](#) ]

### **[UPPERB](#)**

Returns a character string with each ASCII character converted to uppercase. [ [String functions](#) ]

### **[URI\\_PERCENT\\_DECODE](#)**

Decodes a percent-encoded Universal Resource Identifier (URI) according to the RFC 3986 standard. [ [URI functions](#) ]

### **[URI\\_PERCENT\\_ENCODE](#)**

Encodes a Universal Resource Identifier (URI) according to the RFC 3986 standard for percent encoding. [ [URI functions](#) ]

### **[USER](#)**

Returns a VARCHAR containing the name of the user who initiated the current database connection. [ [System information functions](#) ]

### **[USERNAME](#)**

Returns a VARCHAR containing the name of the user who initiated the current database connection. [ [System information functions](#) ]

### **[UUID\\_GENERATE](#)**

Returns a new universally unique identifier (UUID) that is generated based on high-quality randomness from /dev/urandom. [ [UUID functions](#) ]

## **V**

### **[V6\\_ATON](#)**

Converts a string containing a colon-delimited IPv6 network address into a VARBINARY string. [ [IP address functions](#) ]

### **[V6\\_NTOA](#)**

Converts an IPv6 address represented as varbinary to a character string. [ [IP address functions](#) ]

### **[V6\\_SUBNETA](#)**

Returns a VARCHAR containing a subnet address in CIDR (Classless Inter-Domain Routing) format from a binary or alphanumeric IPv6 address. [ [IP address functions](#) ]

### **[V6\\_SUBNETN](#)**

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a varbinary or alphanumeric IPv6 address. [ [IP address functions](#) ]

### **[V6\\_TYPE](#)**

Returns an INTEGER value that classifies the type of the network address passed to it as defined in IETF RFC 4291 section 2.4. [ [IP address functions](#) ]

### **[VALIDATE\\_STATISTICS](#)**

Validates statistics in the XML file generated by EXPORT\_STATISTICS. [ [Statistics management functions](#) ]

### **[VAR\\_POP \[aggregate\]](#)**

Evaluates the population variance for each member of the group. [ [Aggregate functions](#) ]

### **[VAR\\_POP \[analytic\]](#)**

Returns the statistical population variance of a non-null set of numbers (nulls are ignored) in a group within a. [ [Analytic functions](#) ]

### **[VAR\\_SAMP \[aggregate\]](#)**

Evaluates the sample variance for each row of the group. [ [Aggregate functions](#) ]

#### **[VAR\\_SAMP \[analytic\]](#)**

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a. [ [Analytic functions](#) ]

#### **[VARIANCE \[aggregate\]](#)**

Evaluates the sample variance for each row of the group. [ [Aggregate functions](#) ]

#### **[VARIANCE \[analytic\]](#)**

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a. [ [Analytic functions](#) ]

#### **[VERIFY\\_HADOOP\\_CONF\\_DIR](#)**

Verifies that the Hadoop configuration that is used to access HDFS is valid on all Vertica nodes. [ [Hadoop functions](#) ]

#### **[VERSION](#)**

Returns a VARCHAR containing a Vertica node's version information. [ [System information functions](#) ]

### W

#### **[WEEK](#)**

Returns the week of the year for the specified date as an integer, where the first week begins on the first Sunday on or preceding January 1. [ [Date/time functions](#) ]

#### **[WEEK\\_ISO](#)**

Returns the week of the year for the specified date as an integer, where the first week starts on Monday and contains January 4. [ [Date/time functions](#) ]

#### **[WIDTH\\_BUCKET](#)**

Constructs equiwidth histograms, in which the histogram range is divided into intervals (buckets) of identical sizes. [ [Mathematical functions](#) ]

#### **[WITHIN GROUP ORDER BY clause](#)**

Specifies how to sort rows that are grouped by aggregate functions, one of the following:. [ [Aggregate functions](#) ]

### X

#### **[XGB\\_CLASSIFIER](#)**

Trains an XGBoost model for classification on an input relation. [ [Machine learning algorithms](#) ]

#### **[XGB\\_PREDICTOR\\_IMPORTANCE](#)**

Measures the importance of the predictors in an XGBoost model. [ [Model evaluation](#) ]

#### **[XGB\\_REGRESSOR](#)**

Trains an XGBoost model for regression on an input relation. [ [Machine learning algorithms](#) ]

### Y

#### **[YEAR](#)**

Returns an integer that represents the year portion of the specified date. [ [Date/time functions](#) ]

#### **[YEAR\\_ISO](#)**

Returns an integer that represents the year portion of the specified date. [ [Date/time functions](#) ]

### Z

#### **[ZEROIFNULL](#)**

Evaluates to 0 if the column is NULL. [ [NULL-handling functions](#) ]

## Aggregate functions

Aggregate functions summarize data over groups of rows from a query result set. The groups are specified using the [GROUP BY](#) clause. They are allowed only in the select list and in the [HAVING](#) and [ORDER BY](#) clauses of a [SELECT](#) statement (as described in [Aggregate expressions](#)).

Except for COUNT, these functions return a null value when no rows are selected. In particular, SUM of no rows returns NULL, not zero.

In some cases, you can replace an expression that includes multiple aggregates with a single aggregate of an expression. For example [SUM\(x\) + SUM\(y\)](#) can be expressed as [SUM\(x+y\)](#) if neither argument is NULL.

Vertica does not support nested aggregate functions.

You can use some of the simple aggregate functions as analytic (window) functions. See [Analytic functions](#) for details. See also [SQL analytics](#).

Some [collection functions](#) also behave as aggregate functions.

### Note

All functions in this section that have an [analytic](#) function counterpart are appended with [aggregate] to avoid confusion between the two.

## APPROXIMATE\_COUNT\_DISTINCT

Returns the number of distinct non-NULL values in a data set.

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_COUNT_DISTINCT (expression[, error-tolerance])
```

Parameters

### ***expression***

Value to be evaluated using any data type that supports equality comparison.

### ***error-tolerance***

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set ***error-tolerance*** to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

Restrictions

APPROXIMATE\_COUNT\_DISTINCT and DISTINCT aggregates cannot be in the same query block.

Error tolerance

**APPROXIMATE\_COUNT\_DISTINCT**( *x* , ***error-tolerance*** ) returns a value equal to **COUNT(DISTINCT *x*)** , with an error that is lognormally distributed with standard deviation.

Parameter ***error-tolerance*** is optional. Supply this argument to specify the desired standard deviation. ***error-tolerance*** is defined as 2.17 standard deviations, which corresponds to a 97 percent confidence interval:

```
standard-deviation = error-tolerance / 2.17
```

For example:

- ***error-tolerance* = 1**

Default setting, corresponds to a standard deviation

97 percent of the time, **APPROXIMATE\_COUNT\_DISTINCT( *x*,5 )** returns a value between:

- **COUNT(DISTINCT *x*) \* 0.99**
- **COUNT(DISTINCT *x*) \* 1.01**

- ***error-tolerance* = 5**

97 percent of the time, **APPROXIMATE\_COUNT\_DISTINCT( *x* )** returns a value between:

- **COUNT(DISTINCT *x*) \* 0.95**
- **COUNT(DISTINCT *x*) \* 1.05**

A 99 percent confidence interval corresponds to **2.58** standard deviations. To set ***error-tolerance*** confidence level corresponding to 99 (instead of a 97) percent , multiply ***error-tolerance*** by  $2.17 / 2.58 = 0.841$  .

For example, if you specify *error-tolerance* as  $5 * 0.841 = 4.2$ , `APPROXIMATE_COUNT_DISTINCT(x,4.2)` returns values 99 percent of the time between:

- `COUNT (DISTINCT x) * 0.95`
- `COUNT (DISTINCT x) * 1.05`

#### Examples

Count the total number of distinct values in column `product_key` from table `store.store_sales_fact` :

```
=> SELECT COUNT(DISTINCT product_key) FROM store.store_sales_fact;
COUNT

19982
(1 row)
```

Count the approximate number of distinct values in `product_key` with various error tolerances. The smaller the error tolerance, the closer the approximation:

```
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key,5) AS five_pct_accuracy,
 APPROXIMATE_COUNT_DISTINCT(product_key,1) AS one_pct_accuracy,
 APPROXIMATE_COUNT_DISTINCT(product_key,.88) AS point_eighteight_pct_accuracy
FROM store.store_sales_fact;

five_pct_accuracy | one_pct_accuracy | point_eighteight_pct_accuracy
-----+-----+-----
19431 | 19921 | 19921
(1 row)
```

See also

[Approximate count distinct functions](#)

`APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS`

Calculates the number of distinct non-NULL values from the synopsis objects created by [APPROXIMATE\\_COUNT\\_DISTINCT\\_SYNOPSIS](#).

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS (synopsis-obj[, error-tolerance])
```

Parameters

***synopsis-obj***

A synopsis object created by `APPROXIMATE_COUNT_DISTINCT_SYNOPSIS`.

***error-tolerance***

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set *error-tolerance* to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

For more details, see [APPROXIMATE\\_COUNT\\_DISTINCT](#).

Restrictions

`APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS` and `DISTINCT` aggregates cannot be in the same query block.

Examples

The following examples review and compare different ways to obtain a count of unique values in a table column:

Return an exact count of unique values in column `product_key`, from table `store.store_sales_fact` :

```
=> \timing
Timing is on.
=> SELECT COUNT(DISTINCT product_key) from store.store_sales_fact;
count

19982
(1 row)

Time: First fetch (1 row): 553.033 ms. All rows formatted: 553.075 ms
```

Return an approximate count of unique values in column `product_key` :

```
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key) as unique_product_keys
FROM store.store_sales_fact;
unique_product_keys

19921
(1 row)

Time: First fetch (1 row): 394.562 ms. All rows formatted: 394.600 ms
```

Create a synopsis object that represents a set of `store.store_sales_fact` data with unique `product_key` values, store the synopsis in the new table `my_summary` :

```
=> CREATE TABLE my_summary AS SELECT APPROXIMATE_COUNT_DISTINCT_SYNOPSIS (product_key) syn
FROM store.store_sales_fact;
CREATE TABLE
Time: First fetch (0 rows): 582.662 ms. All rows formatted: 582.682 ms
```

Return a count from the saved synopsis:

```
=> SELECT APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(syn) FROM my_summary;
ApproxCountDistinctOfSynopsis

19921
(1 row)

Time: First fetch (1 row): 105.295 ms. All rows formatted: 105.335 ms
```

See also

[Approximate count distinct functions](#)

`APPROXIMATE_COUNT_DISTINCT_SYNOPSIS`

Summarizes the information of distinct non-NULL values and materializes the result set in a VARBINARY or LONG VARBINARY *synopsis* object. The calculated result is within a specified range of error tolerance. You save the synopsis object in a Vertica table for use by [APPROXIMATE\\_COUNT\\_DISTINCT\\_OF\\_SYNOPSIS](#).

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_COUNT_DISTINCT_SYNOPSIS (expression[, error-tolerance])
```

Parameters

**expression**

Value to evaluate using any data type that supports equality comparison.

**error-tolerance**

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set `error-tolerance` to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

For more details, see [APPROXIMATE\\_COUNT\\_DISTINCT](#).

#### Restrictions

APPROXIMATE\_COUNT\_DISTINCT\_SYNOPSIS and DISTINCT aggregates cannot be in the same query block.

#### Examples

See [APPROXIMATE\\_COUNT\\_DISTINCT\\_OF\\_SYNOPSIS](#).

#### See also

[Approximate count distinct functions](#)

APPROXIMATE\_COUNT\_DISTINCT\_SYNOPSIS\_MERGE

Aggregates multiple synopses into one new synopsis. This function is similar to [APPROXIMATE\\_COUNT\\_DISTINCT\\_OF\\_SYNOPSIS](#) but returns one synopsis instead of the count estimate. The benefit of this function is that it speeds up final estimation when calling APPROXIMATE\_COUNT\_DISTINCT\_OF\_SYNOPSIS.

For example, if you need to regularly estimate count distinct of users for a long period of time (such as several years) you can pre-accumulate synopses of days into one synopsis for a year.

#### Behavior type

[Immutable](#)

#### Syntax

```
APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE (synopsis-obj [, error-tolerance])
```

#### Parameters

##### ***synopsis-obj***

An expression that can be evaluated to one or more synopses. Typically a *synopsis-obj* is generated as a binary string by either the [APPROXIMATE\\_COUNT\\_DISTINCT](#) or APPROXIMATE\_COUNT\_DISTINCT\_SYNOPSIS\_MERGE function and is stored in a table column of type VARBINARY or LONG VARBINARY.

##### ***error-tolerance***

Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation.

You can set ***error-tolerance*** to a minimum value of 0.88. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.

If you omit this argument, Vertica uses an error tolerance of 1.25(%)

For more details, see [APPROXIMATE\\_COUNT\\_DISTINCT](#).

#### Examples

See [Approximate count distinct functions](#).

APPROXIMATE\_MEDIAN [*aggregate*]

Computes the approximate median of an expression over a group of rows. The function returns a FLOAT value.

**APPROXIMATE\_MEDIAN** is an alias of [APPROXIMATE\\_PERCENTILE \[\*aggregate\*\]](#) with a parameter of 0.5.

#### Note

**Note** : This function is best suited for large groups of data. If you have a small group of data, use the exact [MEDIAN \[\*analytic\*\]](#) function.

#### Behavior type

[Immutable](#)

#### Syntax

```
APPROXIMATE_MEDIAN (expression)
```

#### Parameters

##### ***expression***

Any FLOAT or INTEGER data type. The function returns the approximate middle value or an interpolated value that would be the approximate

middle value once the values are sorted. Null values are ignored in the calculation.

## Examples

### Tip

For optimal performance when using **GROUP BY** in your query, verify that your table is sorted on the **GROUP BY** column.

The following examples uses this table:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Calculate the approximate median of all sales in this table:

```
=> SELECT APPROXIMATE_MEDIAN (sales) FROM allsales;
APROXIMATE_MEDIAN

 20
(1 row)
```

Modify the query to group sales by state, and obtain the approximate median for each one:

```
=> SELECT state, APPROXIMATE_MEDIAN(sales) FROM allsales GROUP BY state;
state | APPROXIMATE_MEDIAN
-----+-----
MA | 35
NY | 20
(2 rows)
```

See also

- [MEDIAN \[analytic\]](#)
- [PERCENTILE\\_CONT \[analytic\]](#)
- [APPROXIMATE\\_PERCENTILE \[aggregate\]](#)
- [SQL analytics](#)

**APPROXIMATE\_PERCENTILE** [aggregate]

Computes the approximate percentile of an expression over a group of rows. This function returns a FLOAT value.

### Note

**Note** : Use this function when many rows are aggregated into groups. If the number of aggregated rows is small, use the analytic function [PERCENTILE\\_CONT](#).

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_PERCENTILE (column-expression USING PARAMETERS percentiles='percentile-values')
```

Arguments

***column-expression***

A column of FLOAT or INTEGER data types whose percentiles will be calculated. NULL values are ignored.

Parameters

## percentiles

One or more (up to 1000) comma-separated **FLOAT** constants ranging from 0 to 1 inclusive, specifying the percentile values to be calculated.

### Note

**Note** : The deprecated parameter **percentile** , which takes only a single float, continues to be supported for backwards-compatibility.

## Examples

### Tip

For optimal performance when using **GROUP BY** in your query, verify that your table is sorted on the **GROUP BY** column.

The following examples use this table:

```
=> CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

```
=> SELECT * FROM allsales;
```

```
state | name | sales
```

```
-----+-----+-----
MA | A | 60
NY | B | 20
NY | C | 15
NY | F | 40
MA | D | 20
MA | E | 50
MA | G | 10
```

(7 rows)

Calculate the approximate percentile for sales in each state:

```
=> SELECT state, APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentiles='0.5') AS median
```

```
FROM allsales GROUP BY state;
```

```
state | median
```

```
-----+-----
MA | 35
NY | 20
```

(2 rows)

Calculate multiple approximate percentiles for sales in each state:

```
=> SELECT state, APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentiles='0.5,1.0')
```

```
FROM allsales GROUP BY state;
```

```
state | APPROXIMATE_PERCENTILE
```

```
-----+-----
MA | [35.0,60.0]
NY | [20.0,40.0]
```

(2 rows)

Calculate multiple approximate percentiles for sales in each state and show results for each percentile in separate columns:

```
=> SELECT ps[0] as q0, ps[1] as q1, ps[2] as q2, ps[3] as q3, ps[4] as q4
FROM (SELECT APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentiles='0, 0.25, 0.5, 0.75, 1')
AS ps FROM allsales GROUP BY state) as s1;
q0 | q1 | q2 | q3 | q4
-----+-----+-----+-----+-----
10.0 | 17.5 | 35.0 | 52.5 | 60.0
15.0 | 17.5 | 20.0 | 30.0 | 40.0
(2 rows)
```

See also

- [APPROXIMATE\\_QUANTILES](#)
- [MEDIAN](#)
- [PERCENTILE\\_CONT](#)
- [SQL analytics](#)

## APPROXIMATE\_QUANTILES

Computes an array of weighted, approximate percentiles of a column within some user-specified error. This algorithm is similar to [APPROXIMATE\\_PERCENTILE \[aggregate\]](#), which instead returns a single percentile.

The performance of this function depends entirely on the specified epsilon and the size of the provided array.

The OVER clause for this function must be empty.

Behavior type

[Immutable](#)

Syntax

```
APPROXIMATE_QUANTILES (column USING PARAMETERS [nquantiles=n], [epsilon=error]) OVER() FROM table
```

Parameters

### *column*

The **INTEGER** or **FLOAT** column for which to calculate the percentiles. NULL values are ignored.

### *n*

An integer that specifies the number of desired quantiles in the returned array.

**Default:** 11

### *error*

The allowed error for any returned percentile. Specifically, for an array of size  $N$ , the specified error  $\epsilon$  (epsilon) for the  $\varphi$ -quantile guarantees that the rank  $r$  of the return value with respect to the rank  $\lfloor \varphi N \rfloor$  of the exact value is such that:

$$\lfloor (\varphi - \epsilon)N \rfloor \leq r \leq \lfloor (\varphi + \epsilon)N \rfloor$$

For  $n$  quantiles, if the error  $\epsilon$  is specified such that  $\epsilon > 1/n$ , this function will return non-deterministic results.

**Default:** 0.001

### *table*

The table containing *column*.

Examples

The following example uses this table:

```
=> CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

```
=> SELECT * FROM allsales;
```

```
state | name | sales
```

```
-----+-----
MA | A | 60
NY | B | 20
NY | C | 15
NY | F | 40
MA | D | 20
MA | E | 50
MA | G | 10
(7 rows)
```

This call to APPROXIMATE\_QUANTILES returns a 6-element array of approximate percentiles, one for each quantile. Each quantile relates to the percentile by a factor of 100. For example, the second entry in the output indicates that 15 is the 0.2-quantile of the input column, so 15 is the 20th percentile of the input column.

```
=> SELECT APPROXIMATE_QUANTILES(sales USING PARAMETERS nquantiles=6) OVER() FROM allsales;
```

```
Quantile | Value
```

```
-----+-----
0 | 10
0.2 | 15
0.4 | 20
0.6 | 40
0.8 | 50
1 | 60
(6 rows)
```

## ARGMAX\_AGG

Takes two arguments *target* and *arg*, where both are columns or column expressions in the queried dataset. ARGMAX\_AGG finds the row with the highest non-null value in *target* and returns the value of *arg* in that row. If multiple rows contain the highest *target* value, ARGMAX\_AGG returns *arg* from the first row that it finds. Use the WITHIN GROUP ORDER BY clause to control which row ARGMAX\_AGG finds first.

### Behavior type

[Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique values within the group; otherwise [Volatile](#).

### Syntax

```
ARGMAX_AGG (target, arg) [within-group-order-by-clause]
```

### Arguments

#### *target*, *arg*

Columns in the queried dataset.

#### Note

The *target* argument cannot reference a [spatial data type](#) column, GEOMETRY or GEOGRAPHY.

### [\[within-group-order-by-clause\]](#)/[sql-reference/functions/aggregate-functions/within-group-order-by-clause.html](#))

Sorts target values within each group of rows:

```
WITHIN GROUP (ORDER BY { column-expression[sort-qualifiers] }[,...])
```

*sort-qualifiers* :

```
{ ASC | DESC [NULLS { FIRST | LAST | AUTO }] }
```

Use this clause to determine which row is returned when multiple rows contain the highest target value; otherwise, results are likely to vary with each iteration of the same query.

#### Tip

WITHIN GROUP ORDER BY can consume a large amount of memory per group. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

#### Examples

The following example calls ARGMAX\_AGG in a [WITH clause](#) to find which employees in each region are at or near retirement age. If multiple employees within each region have the same age, ARGMAX\_AGG chooses the employees with the highest salary level and returns with their IDs. The primary query returns with details on the employees selected from each region:

```
=> WITH r AS (SELECT employee_region, ARGMAX_AGG(employee_age, employee_key)
 WITHIN GROUP (ORDER BY annual_salary DESC) emp_id
 FROM employee_dim GROUP BY employee_region ORDER BY employee_region)
SELECT r.employee_region, ed.annual_salary AS highest_salary, employee_key,
 ed.employee_first_name||' '||ed.employee_last_name AS employee_name, ed.employee_age
 FROM r JOIN employee_dim ed ON r.emp_id = ed.employee_key ORDER BY ed.employee_region;
 employee_region | highest_salary | employee_key | employee_name | employee_age
```

```
-----+-----+-----+-----+-----+
East | 927335 | 70 | Sally Gauthier | 65
MidWest | 177716 | 869 | Rebecca McCabe | 65
NorthWest | 100300 | 7597 | Kim Jefferson | 65
South | 196454 | 275 | Alexandra Harris | 65
SouthWest | 198669 | 1043 | Seth Stein | 65
West | 197203 | 681 | Seth Jones | 65
(6 rows)
```

See also

[ARGMIN\\_AGG](#)

ARGMIN\_AGG

Takes two arguments *target* and *arg*, where both are columns or column expressions in the queried dataset. ARGMIN\_AGG finds the row with the lowest non-null value in *target* and returns the value of *arg* in that row. If multiple rows contain the lowest *target* value, ARGMIN\_AGG returns *arg* from the first row that it finds. Use the WITHIN GROUP ORDER BY clause to control which row ARGMIN\_AGG finds first.

Behavior type

[Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique values within the group; otherwise [Volatile](#).

Syntax

```
ARGMIN_AGG (target, arg) [within-group-order-by-clause]
```

Arguments

*target*, *arg*

Columns in the queried dataset.

#### Note

The *target* argument cannot reference a [spatial data type](#) column, GEOMETRY or GEOGRAPHY.

[\[within-group-order-by-clause\]\(/sql-reference/functions/aggregate-functions/within-group-order-by-clause.html\)](#)

Sorts target values within each group of rows:

```
WITHIN GROUP (ORDER BY { column-expression[sort-qualifiers] }{...})
```

*sort-qualifiers* :

```
{ ASC | DESC [NULLS { FIRST | LAST | AUTO }] }
```

Use this clause to determine which row is returned when multiple rows contain the lowest target value; otherwise, results are likely to vary with each iteration of the same query.

### Tip

WITHIN GROUP ORDER BY can consume a large amount of memory per group. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

### Examples

The following example calls ARGMIN\_AGG in a [WITH clause](#) to find the lowest salary among all employees in each region, and returns with the lowest-paid employee IDs. The primary query returns with the salary amounts and employee names:

```
=> WITH msr (employee_region, emp_id) AS
 (SELECT employee_region, argmin_agg(annual_salary, employee_key) lowest_paid_employee FROM employee_dim GROUP BY employee_region)
SELECT msr.employee_region, ed.annual_salary AS lowest_salary, ed.employee_first_name||' '||ed.employee_last_name AS employee_name
FROM msr JOIN employee_dim ed ON msr.emp_id = ed.employee_key ORDER BY annual_salary DESC;
 employee_region | lowest_salary | employee_name
-----+-----+-----
NorthWest | 20913 | Raja Garnett
SouthWest | 20750 | Seth Moore
West | 20443 | Midori Taylor
South | 20363 | David Bauer
East | 20306 | Craig Jefferson
MidWest | 20264 | Dean Vu
(6 rows)
```

See also

[ARGMAX\\_AGG](#)

AVG [aggregate]

Computes the average (arithmetic mean) of an expression over a group of rows. AVG always returns a DOUBLE PRECISION value.

The AVG aggregate function differs from the [AVG](#) analytic function, which computes the average of an expression over a group of rows within a [window](#).

Behavior type

[Immutable](#)

Syntax

```
AVG ([ALL | DISTINCT] expression)
```

Parameters

#### ALL

Invokes the aggregate function for all rows in the group (default).

#### DISTINCT

Invokes the aggregate function for all distinct non-null values of the expression found in the group.

#### *expression*

The value whose average is calculated over a set of rows, any expression that can have a DOUBLE PRECISION result.

Overflow handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#).

Examples

The following query returns the average income from the customer table:

```
=> SELECT AVG(annual_income) FROM customer_dimension;
 AVG

2104270.6485
(1 row)
```

See also

- [COUNT \[aggregate\]](#)
- [SUM \[aggregate\]](#)
- [Numeric data types](#)

## BIT\_AND

Takes the bitwise AND of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior type

[Immutable](#)

Syntax

```
BIT_AND (expression)
```

Parameters

***expression***

The BINARY or VARBINARY input value to evaluate. BIT\_AND operates on VARBINARY types explicitly and on BINARY types implicitly through [casts](#).

Returns

BIT\_AND returns:

- The same value as the argument data type.
- 1 for each bit compared, if all bits are 1; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values `ff`, `null`, and `f`, BIT\_AND ignores the null value and extends the value `f` to `f0`.

Examples

The example that follows uses table `t` with a single column of VARBINARY data type:

```
=> CREATE TABLE t (c VARBINARY(2));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table `t` to see column `c` output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX

ff00
ffff
f00f
(3 rows)
```

Query table `t` to get the AND value for column `c`:

```
=> SELECT TO_HEX(BIT_AND(c)) FROM t;
TO_HEX

f000
(1 row)
```

The function is applied pairwise to all values in the group, resulting in `f000`, which is determined as follows:

1. `ff00` (record 1) is compared with `ffff` (record 2), which results in `ff00`.
2. The result from the previous comparison is compared with `f00f` (record 3), which results in `f000`.

See also

[Binary data types \(BINARY and VARBINARY\)](#)

BIT\_OR

Takes the bitwise OR of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior type

## [Immutable](#)

### Syntax

```
BIT_OR (expression)
```

### Parameters

#### ***expression***

The BINARY or VARBINARY input value to evaluate. BIT\_OR operates on VARBINARY types explicitly and on BINARY types implicitly through [casts](#).

### Returns

**BIT\_OR** returns:

- The same value as the argument data type.
- 1 for each bit compared, if any bit is 1; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values **ff**, **null**, and **f**, the function ignores the null value and extends the value **f** to **f0**.

### Examples

The example that follows uses table **t** with a single column of **VARBINARY** data type:

```
=> CREATE TABLE t (c VARBINARY(2));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table **t** to see column **c** output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX

ff00
ffff
f00f
(3 rows)
```

Query table **t** to get the OR value for column **c** :

```
=> SELECT TO_HEX(BIT_OR(c)) FROM t;
TO_HEX

ffff
(1 row)
```

The function is applied pairwise to all values in the group, resulting in **ffff**, which is determined as follows:

1. **ff00** (record 1) is compared with **ffff**, which results in **ffff**.
2. The **ff00** result from the previous comparison is compared with **f00f** (record 3), which results in **ffff**.

See also

[Binary data types \(BINARY and VARBINARY\)](#)

### BIT\_XOR

Takes the bitwise **XOR** of all non-null input values. If the input parameter is **NULL**, the return value is also **NULL**.

### Behavior type

## [Immutable](#)

### Syntax

```
BIT_XOR (expression)
```

### Parameters

#### ***expression***

The BINARY or VARBINARY input value to evaluate. BIT\_XOR operates on VARBINARY types explicitly and on BINARY types implicitly through [casts](#).

## Returns

**BIT\_XOR** returns:

- The same value as the argument data type.
- 1 for each bit compared, if there are an odd number of arguments with set bits; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values **ff**, **null**, and **f**, the function ignores the null value and extends the value **f** to **f0**.

## Examples

First create a sample table and projections with binary columns:

The example that follows uses table **t** with a single column of **VARBINARY** data type:

```
=> CREATE TABLE t (c VARBINARY(2));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table **t** to see column **c** output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX

ff00
ffff
f00f
(3 rows)
```

Query table **t** to get the XOR value for column **c** :

```
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
TO_HEX

f0f0
(1 row)
```

See also

[Binary data types \(BINARY and VARBINARY\)](#)

**BOOL\_AND** [aggregate]

Processes Boolean values and returns a Boolean value result. If all input values are true, **BOOL\_AND** returns **t**. Otherwise it returns **f** (false).

Behavior type

[Immutable](#)

Syntax

```
BOOL_AND (expression)
```

Parameters

***expression***

A [Boolean data type](#) or any non-Boolean data type that can be implicitly coerced to a Boolean data type.

Examples

The following example shows how to use aggregate functions **BOOL\_AND**, **BOOL\_OR**, and **BOOL\_XOR**. The sample table **mixers** includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```

=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
OUTPUT

 8
(1 row)

```

Query the table. The result shows models that have two blue ( **BOOL\_AND** ), one or two blue ( **BOOL\_OR** ), and specifically not more than one blue ( **BOOL\_XOR** ) mixer.

```

=> SELECT model,
BOOL_AND(colors= 'blue')AS two_blue,
BOOL_OR(colors= 'blue')AS one_or_two_blue,
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;

```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

(4 rows)

See also

- [BOOL\\_OR \[aggregate\]](#)
- [BOOL\\_XOR \[aggregate\]](#)
- [Boolean data type](#)

**BOOL\_OR** [aggregate]

Processes Boolean values and returns a Boolean value result. If at least one input value is true, **BOOL\_OR** returns **t** . Otherwise, it returns **f** .

Behavior type

[Immutable](#)

Syntax

```

BOOL_OR (expression)

```

Parameters

**expression**

A [Boolean data type](#) or any non-Boolean data type that can be implicitly coerced to a Boolean data type.

Examples

The following example shows how to use aggregate functions **BOOL\_AND** , **BOOL\_OR** , and **BOOL\_XOR** . The sample table **mixers** includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
OUTPUT
```

```

 8
(1 row)
```

Query the table. The result shows models that have two blue ( **BOOL\_AND** ), one or two blue ( **BOOL\_OR** ), and specifically not more than one blue ( **BOOL\_XOR** ) mixer.

```
=> SELECT model,
BOOL_AND(colors= 'blue')AS two_blue,
BOOL_OR(colors= 'blue')AS one_or_two_blue,
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;
```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

(4 rows)

See also

- [BOOL\\_OR \[analytic\]](#)
- [BOOL\\_AND \[aggregate\]](#)
- [BOOL\\_XOR \[aggregate\]](#)
- [Boolean data type](#)

**BOOL\_XOR** [aggregate]

Processes Boolean values and returns a Boolean value result. If specifically only one input value is true, **BOOL\_XOR** returns **t**. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
BOOL_XOR (expression)
```

Parameters

**expression**

A [Boolean data type](#) or any non-Boolean data type that can be implicitly coerced to a Boolean data type.

## Examples

The following example shows how to use aggregate functions `BOOL_AND` , `BOOL_OR` , and `BOOL_XOR` . The sample table `mixers` includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers
SELECT 'beginner', 'green'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'intermediate', 'blue'
UNION ALL
SELECT 'advanced', 'green'
UNION ALL
SELECT 'advanced', 'blue'
UNION ALL
SELECT 'professional', 'blue'
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
OUTPUT

 8
(1 row)
```

Query the table. The result shows models that have two blue ( `BOOL_AND` ), one or two blue ( `BOOL_OR` ), and specifically not more than one blue ( `BOOL_XOR` ) mixer.

```
=> SELECT model,
BOOL_AND(colors= 'blue')AS two_blue,
BOOL_OR(colors= 'blue')AS one_or_two_blue,
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;
```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

(4 rows)

- [BOOL\\_OR \[aggregate\]](#)
- [Boolean data type](#)

## CORR

Returns the `DOUBLE PRECISION` coefficient of correlation of a set of expression pairs, as per the [Pearson correlation coefficient](#). `CORR` eliminates expression pairs where either expression in the pair is `NULL` . If no rows remain, the function returns `NULL` .

## Syntax

```
CORR (expression1, expression2)
```

## Parameters

### *expression1*

The dependent **DOUBLE PRECISION** expression

### *expression2*

The independent **DOUBLE PRECISION** expression

## Examples

```
=> SELECT CORR (Annual_salary, Employee_age) FROM employee_dimension;
CORR

-0.00719153413192422
(1 row)
```

## COUNT [aggregate]

Returns as a BIGINT the number of rows in each group where the expression is not NULL. If the query has no GROUP BY clause, COUNT returns the number of table rows.

The COUNT aggregate function differs from the [COUNT](#) analytic function, which returns the number over a group of rows within a [window](#).

## Behavior type

[Immutable](#)

## Syntax

```
COUNT ([*] [ALL | DISTINCT] expression)
```

## Parameters

\*

Specifies to count all rows in the specified table or each group.

### **ALL | DISTINCT**

Specifies how to count rows where *expression* has a non-null value:

- **ALL** (default): Counts all rows where *expression* evaluates to a non-null value.
- **DISTINCT** : Counts all rows where *expression* evaluates to a distinct non-null value.

### *expression*

The column or expression whose non-null values are counted.

## Examples

The following query returns the number of distinct values in a column:

```
=> SELECT COUNT (DISTINCT date_key) FROM date_dimension;
COUNT

1826
(1 row)
```

This example returns the number of distinct return values from an expression:

```
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
COUNT

21560
(1 row)
```

You can create an equivalent query using the LIMIT keyword to restrict the number of rows returned:

```
=> SELECT COUNT(date_key + product_key) FROM inventory_fact GROUP BY date_key LIMIT 10;
```

COUNT

```

173
31
321
113
286
84
244
238
145
202
(10 rows)
```

The following query uses GROUP BY to count distinct values within groups:

```
=> SELECT product_key, COUNT (DISTINCT date_key) FROM inventory_fact
GROUP BY product_key LIMIT 10;
```

product\_key | count

```
-----+-----
1 | 12
2 | 18
3 | 13
4 | 17
5 | 11
6 | 14
7 | 13
8 | 17
9 | 15
10 | 12
(10 rows)
```

The following query returns the number of distinct products and the total inventory within each date key:

```
=> SELECT date_key, COUNT (DISTINCT product_key), SUM(qty_in_stock) FROM inventory_fact
GROUP BY date_key LIMIT 10;
```

date\_key | count | sum

```
-----+-----+-----
1 | 173 | 88953
2 | 31 | 16315
3 | 318 | 156003
4 | 113 | 53341
5 | 285 | 148380
6 | 84 | 42421
7 | 241 | 119315
8 | 238 | 122380
9 | 142 | 70151
10 | 202 | 95274
(10 rows)
```

This query selects each distinct `product_key` value and then counts the number of distinct `date_key` values for all records with the specific `product_key` value. It also counts the number of distinct `warehouse_key` values in all records with the specific `product_key` value:

```
=> SELECT product_key, COUNT (DISTINCT date_key), COUNT (DISTINCT warehouse_key) FROM inventory_fact
GROUP BY product_key LIMIT 15;
```

```
product_key | count | count
```

```
-----+-----+-----
 1 | 12 | 12
 2 | 18 | 18
 3 | 13 | 12
 4 | 17 | 18
 5 | 11 | 9
 6 | 14 | 13
 7 | 13 | 13
 8 | 17 | 15
 9 | 15 | 14
10 | 12 | 12
11 | 11 | 11
12 | 13 | 12
13 | 9 | 7
14 | 13 | 13
15 | 18 | 17
```

(15 rows)

This query selects each distinct `product_key` value, counts the number of distinct `date_key` and `warehouse_key` values for all records with the specific `product_key` value, and then sums all `qty_in_stock` values in records with the specific `product_key` value. It then returns the number of `product_version` values in records with the specific `product_key` value:

```
=> SELECT product_key, COUNT (DISTINCT date_key),
COUNT (DISTINCT warehouse_key),
SUM (qty_in_stock),
COUNT (product_version)
FROM inventory_fact GROUP BY product_key LIMIT 15;
```

```
product_key | count | count | sum | count
```

```
-----+-----+-----+-----+-----
 1 | 12 | 12 | 5530 | 12
 2 | 18 | 18 | 9605 | 18
 3 | 13 | 12 | 8404 | 13
 4 | 17 | 18 | 10006 | 18
 5 | 11 | 9 | 4794 | 11
 6 | 14 | 13 | 7359 | 14
 7 | 13 | 13 | 7828 | 13
 8 | 17 | 15 | 9074 | 17
 9 | 15 | 14 | 7032 | 15
10 | 12 | 12 | 5359 | 12
11 | 11 | 11 | 6049 | 11
12 | 13 | 12 | 6075 | 13
13 | 9 | 7 | 3470 | 9
14 | 13 | 13 | 5125 | 13
15 | 18 | 17 | 9277 | 18
```

(15 rows)

Returns the population covariance for a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **COVAR\_POP** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **NULL** .

#### Syntax

```
SELECT COVAR_POP (expression1, expression2)
```

#### Parameters

##### **expression1**

The dependent **DOUBLE PRECISION** expression

##### **expression2**

The independent **DOUBLE PRECISION** expression

#### Examples

```
=> SELECT COVAR_POP (Annual_salary, Employee_age)
 FROM employee_dimension;
 COVAR_POP

-9032.34810730019
(1 row)
```

#### COVAR\_SAMP

Returns the sample covariance for a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **COVAR\_SAMP** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **NULL** .

#### Syntax

```
SELECT COVAR_SAMP (expression1, expression2)
```

#### Parameters

##### **expression1**

The dependent **DOUBLE PRECISION** expression

##### **expression2**

The independent **DOUBLE PRECISION** expression

#### Examples

```
=> SELECT COVAR_SAMP (Annual_salary, Employee_age)
 FROM employee_dimension;
 COVAR_SAMP

-9033.25143244343
(1 row)
```

#### GROUP\_ID

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. This function returns one or more integers, starting with zero (0), as identifiers.

For the number of duplicates *n* for a particular grouping, GROUP\_ID returns a range of sequential numbers, 0 to *n*-1. For the first each unique group it encounters, GROUP\_ID returns the value 0. If GROUP\_ID finds the same grouping again, the function returns 1, then returns 2 for the next found grouping, and so on.

#### Note

Use **GROUP\_ID** only in **SELECT** statements that contain a **GROUP BY** aggregate: **CUBE**, **GROUPING SETS**, and **ROLLUP**.

#### Behavior type

[Immutable](#)

#### Syntax

```
GROUP_ID ()
```

## Examples

This example shows how GROUP\_ID creates unique identifiers when a query produces duplicate groupings. For an expenses table, the following query groups the results by category of expense and year and rolls up the sum for those two columns. The results have duplicate groupings for category and NULL. The first grouping has a GROUP\_ID of 0, and the second grouping has a GROUP\_ID of 1.

```
=> SELECT Category, Year, SUM(Amount), GROUPING_ID(Category, Year),
 GROUP_ID() FROM expenses GROUP BY Category, ROLLUP(Category, Year)
 ORDER BY Category, Year, GROUPING_ID();
Category | Year | SUM | GROUPING_ID | GROUP_ID
```

Category	Year	SUM	GROUPING_ID	GROUP_ID
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	1	0
Books		99.96	1	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	1	1
Electricity		449.96	1	0

- [GROUPING\\_ID](#)
- [GROUPING SETS aggregate](#)
- [GROUP BY clause](#)
- [ROLLUP aggregate](#)

## GROUPING

Disambiguates the use of **NULL** values when **GROUP BY** queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. Such **NULL** values from the original data can also occur in rows. **GROUPING** returns 1, if the value of *expression* is:

- **NULL**, representing an aggregated value
- 0 for any other value, including **NULL** values in rows

### Note

Use **GROUPING** only in **SELECT** statements that contain a **GROUP BY** aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

Behavior type

[Immutable](#)

Syntax

```
GROUPING (expression)
```

Parameters

***expression***

An expression in the **GROUP BY** clause

Examples

The following query uses the **GROUPING** function, taking one of the **GROUP BY** expressions as an argument. For each row, **GROUPING** returns one of the following:

- **0**: The column is part of the group for that row
- **1**: The column is not part of the group for that row

The 1 in the **GROUPING(Year)** column for electricity and books indicates that these values are subtotals. The right-most column values for both **GROUPING(Category)** and **GROUPING(Year)** are **1**. This value indicates that neither column contributed to the **GROUP BY**. The final row represents the total sales.

```
=> SELECT Category, Year, SUM(Amount),
 GROUPING(Category), GROUPING(Year) FROM expenses
 GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
 Category | Year | SUM | GROUPING | GROUPING
```

Category	Year	SUM	GROUPING	GROUPING
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	0	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	0	1
		549.92	1	1

- [GROUPING\\_ID](#)
- [GROUPING SETS aggregate](#)
- [GROUP BY clause](#)
- [ROLLUP aggregate](#)

## GROUPING\_ID

Concatenates the set of Boolean values generated by the [GROUPING](#) function into a bit vector. [GROUPING\\_ID](#) treats the bit vector as a binary number and returns it as a base-10 value that identifies the grouping set combination.

By using [GROUPING\\_ID](#) you avoid the need for multiple, individual [GROUPING](#) functions. [GROUPING\\_ID](#) simplifies row-filtering conditions, because rows of interest are identified using a single return from [GROUPING\\_ID = n](#). Use [GROUPING\\_ID](#) to identify grouping combinations.

### Note

Use [GROUPING\\_ID](#) only in [SELECT](#) statements that contain a [GROUP BY](#) aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

Behavior type

[Immutable](#)

Syntax

```
GROUPING_ID ([expression[,...]])
```

### expression

An expression that matches one of the expressions in the [GROUP BY](#) clause.

If the [GROUP BY](#) clause includes a list of expressions, [GROUPING\\_ID](#) returns a number corresponding to the [GROUPING](#) bit vector associated with a row.

Examples

This example shows how calling [GROUPING\\_ID](#) without an expression returns the [GROUPING](#) bit vector associated with a full set of multilevel aggregate expressions. The [GROUPING\\_ID](#) value is comparable to [GROUPING\\_ID\(a,b\)](#) because [GROUPING\\_ID\(\)](#) includes all columns in the [GROUP BY ROLLUP](#) :

```
=> SELECT a,b,COUNT(*), GROUPING_ID() FROM T GROUP BY ROLLUP(a,b);
```

In the following query, the [GROUPING\(Category\)](#) and [GROUPING\(Year\)](#) columns have three combinations:

- 0,0
- 0,1
- 1,1

```
=> SELECT Category, Year, SUM(Amount),
 GROUPING(Category), GROUPING(Year) FROM expenses
 GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
Category | Year | SUM | GROUPING | GROUPING
-----+-----+-----+-----+-----
Books | 2005 | 39.98 | 0 | 0
Books | 2007 | 29.99 | 0 | 0
Books | 2008 | 29.99 | 0 | 0
Books | | 99.96 | 0 | 1
Electricity | 2005 | 109.99 | 0 | 0
Electricity | 2006 | 109.99 | 0 | 0
Electricity | 2007 | 229.98 | 0 | 0
Electricity | | 449.96 | 0 | 1
 | | 549.92 | 1 | 1
```

**GROUPING\_ID** converts these values as follows:

Binary Set Values	Decimal Equivalents
00	0
01	1
11	3
0	Category, Year

The following query returns the single number for each **GROUP BY** level that appears in the `gr_id` column:

```
=> SELECT Category, Year, SUM(Amount),
 GROUPING(Category),GROUPING(Year),GROUPING_ID(Category,Year) AS gr_id
 FROM expenses GROUP BY ROLLUP(Category, Year);
Category | Year | SUM | GROUPING | GROUPING | gr_id
-----+-----+-----+-----+-----+-----
Books | 2008 | 29.99 | 0 | 0 | 0
Books | 2005 | 39.98 | 0 | 0 | 0
Electricity | 2007 | 229.98 | 0 | 0 | 0
Books | 2007 | 29.99 | 0 | 0 | 0
Electricity | 2005 | 109.99 | 0 | 0 | 0
Electricity | | 449.96 | 0 | 1 | 1
 | | 549.92 | 1 | 1 | 3
Electricity | 2006 | 109.99 | 0 | 0 | 0
Books | | 99.96 | 0 | 1 | 1
```

The `gr_id` value determines the **GROUP BY** level for each row:

### GROUP BY Level

GROUP BY Row Level

**3**

Total sum

**1**

Category

**0**

Category, year

You can also use the [DECODE](#) function to give the values more meaning by comparing each search value individually:

```
=> SELECT Category, Year, SUM(AMOUNT), DECODE(GROUPING_ID(Category, Year),
 3, 'Total',
 1, 'Category',
 0, 'Category,Year')
AS GROUP_NAME FROM expenses GROUP BY ROLLUP(Category, Year);
Category | Year | SUM | GROUP_NAME
-----+-----+-----+-----
Electricity | 2006 | 109.99 | Category,Year
Books | | 99.96 | Category
Electricity | 2007 | 229.98 | Category,Year
Books | 2007 | 29.99 | Category,Year
Electricity | 2005 | 109.99 | Category,Year
Electricity | | 449.96 | Category
| | 549.92 | Total
Books | 2005 | 39.98 | Category,Year
Books | 2008 | 29.99 | Category,Year
```

- [ROLLUP aggregate](#)

## LISTAGG

Transforms non-null values from a group of rows into a list of values that are delimited by commas (default) or a configurable separator. LISTAGG can be used to denormalize rows into a string of concatenated values.

Behavior type

[Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique values within the aggregated list; otherwise [Volatile](#).

Syntax

```
LISTAGG (aggregate-expression [USING PARAMETERS parameter=value[,...]]) [within-group-order-by-clause]
```

Arguments

### ***aggregate-expression***

Aggregation of one or more columns or column expressions to select from the source table or view.

LISTAGG does not support [spatial data types](#) directly. In order to pass column data of this type, convert the data to strings with the geospatial function [ST\\_AsText](#).

### **Caution**

Converted spatial data frequently contains commas. LISTAGG uses comma as the default separator character. To avoid ambiguous output, override this default by setting the function's [separator](#) parameter to another character.

### ***[within-group-order-by-clause]*** ([/sql-reference/functions/aggregate-functions/within-group-order-by-clause.html](#))

Sorts aggregated values within each group of rows, where *column-expression* is typically a column in *aggregate-expression* :

```
WITHIN GROUP (ORDER BY { column-expression[sort-qualifiers] }[,...])
```

*sort-qualifiers* :

```
{ ASC | DESC [NULLS { FIRST | LAST | AUTO }] }
```

### **Tip**

WITHIN GROUP ORDER BY can consume a large amount of memory per group. Including wide strings in the aggregate expression can also adversely affect performance. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

## Parameters

Parameter name	Set to...
<code>max_length</code>	An integer or integer expression that specifies in bytes the maximum length of the result, up to 32M. <b>Default:</b> 1024
<code>separator</code>	Separator string of length 0 to 80, inclusive. A length of 0 concatenates the output with no separators. <b>Default:</b> comma ( , )
<code>on_overflow</code>	Specifies behavior when the result overflows the <code>max_length</code> setting, one of the following strings: <ul style="list-style-type: none"><li>• <b>ERROR</b> (default): Return an error when overflow occurs.</li><li>• <b>TRUNCATE</b> : Remove any characters that exceed <code>max_length</code> setting from the query result, and return the truncated string.</li></ul>

## Privileges

None

## Examples

In the following query, the aggregated results in the `CityState` column use the string " | " as a separator. The outer GROUP BY clause groups the output rows according to their `Region` values. Within each group, the aggregated list items are sorted according to their `city` values, as per the WITHIN GROUP ORDER BY clause:

```

=> \x
Expanded display is on.
=> WITH cd AS (SELECT DISTINCT (customer_city) city, customer_state, customer_region FROM customer_dimension)
SELECT customer_region Region, LISTAGG(city||', '||customer_state USING PARAMETERS separator='|')
 WITHIN GROUP (ORDER BY city) CityAndState FROM cd GROUP BY region ORDER BY region;
-[RECORD 1]+-----
Region | East

```

## MAX [aggregate]

Returns the greatest value of an expression over a group of rows. The return value has the same type as the expression data type.

The [MAX analytic function](#) differs from the aggregate function, in that it returns the maximum value of an expression over a group of rows within a [window](#).

Aggregate functions **MIN** and **MAX** can operate with Boolean values. **MAX** can act upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean. If at least one input value is true, **MAX** returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, **MIN** returns **t** (true) if all input values are true. Otherwise it returns **f**.

## Behavior type

[Immutable](#)

## Syntax

```
MAX (expression)
```

## Parameters

### **expression**

Any expression for which the maximum value is calculated, typically a [column reference](#).

## Examples

The following query returns the largest value in column `sales_dollar_amount`.

```
=> SELECT MAX(sales_dollar_amount) AS highest_sale FROM store.store_sales_fact;
highest_sale

 600
(1 row)
```

The following example shows you the difference between the **MIN** and **MAX** aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for **MIN** and **MAX**.

```
=> CREATE TABLE min_max_functions (torf BOOL);

=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
torf

t
f
(2 rows)

=> SELECT min(torf) FROM min_max_functions;
min

f
(1 row)

=> SELECT max(torf) FROM min_max_functions;
max

t
(1 row)
```

See also

[Data aggregation](#)

MIN [aggregate]

Returns the smallest value of an expression over a group of rows. The return value has the same type as the expression data type.

The **MIN analytic function** differs from the aggregate function, in that it returns the minimum value of an expression over a group of rows within a [window](#).

Aggregate functions **MIN** and **MAX** can operate with Boolean values. **MAX** can act upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean. If at least one input value is true, **MAX** returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, **MIN** returns **t** (true) if all input values are true. Otherwise it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
MIN (expression)
```

## Parameters

### **expression**

Any expression for which the minimum value is calculated, typically a [column reference](#).

## Examples

The following query returns the lowest salary from the **employee** dimension table.

This example shows how you can query to return the lowest salary from the **employee** dimension table.

```
=> SELECT MIN(annual_salary) AS lowest_paid FROM employee_dimension;
lowest_paid

 1200
(1 row)
```

The following example shows you the difference between the **MIN** and **MAX** aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for **MIN** and **MAX** .

```
=> CREATE TABLE min_max_functions (torf BOOL);
=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
torf

t
f
(2 rows)

=> SELECT min(torf) FROM min_max_functions;
min

f
(1 row)

=> SELECT max(torf) FROM min_max_functions;
max

t
(1 row)
```

See also

[Data aggregation](#)

REGR\_AVGX

Returns the **DOUBLE PRECISION** average of the independent expression in an expression pair. **REGR\_AVGX** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR\_AVGX** returns **NULL** .

Syntax

```
SELECT REGR_AVGX (expression1, expression2)
```

Parameters

***expression1***

The dependent **DOUBLE PRECISION** expression

***expression2***

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_AVGX (Annual_salary, Employee_age)
 FROM employee_dimension;
REGR_AVGX

 39.321
(1 row)
```

REGR\_AVGY

Returns the **DOUBLE PRECISION** average of the dependent expression in an expression pair. The function eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **NULL** .

Syntax

```
REGR_AVGY (expression1, expression2)
```

Parameters

***expression1***

The dependent **DOUBLE PRECISION** expression

***expression2***

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_AVGY (Annual_salary, Employee_age)
 FROM employee_dimension;
REGR_AVGY

58354.4913
(1 row)
```

REGR\_COUNT

Returns the count of all rows in an expression pair. The function eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, the function returns **0** .

Syntax

```
SELECT REGR_COUNT (expression1, expression2)
```

Parameters

***expression1***

The dependent **DOUBLE PRECISION** expression

***expression2***

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_COUNT (Annual_salary, Employee_age) FROM employee_dimension;
REGR_COUNT

10000
(1 row)
```

REGR\_INTERCEPT

Returns the y-intercept of the regression line determined by a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **REGR\_INTERCEPT** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR\_INTERCEPT** returns **NULL** .

Syntax

```
SELECT REGR_INTERCEPT (expression1, expression2)
```

Parameters

***expression1***

The dependent **DOUBLE PRECISION** expression

***expression2***

The independent **DOUBLE PRECISION** expression

Examples

```
=> SELECT REGR_INTERCEPT (Annual_salary, Employee_age) FROM employee_dimension;
 REGR_INTERCEPT
```

```

59929.5490163437
(1 row)
```

## REGR\_R2

Returns the square of the correlation coefficient of a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **REGR\_R2** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR\_R2** returns **NULL** .

### Syntax

```
SELECT REGR_R2 (expression1, expression2)
```

### Parameters

#### **expression1**

The dependent **DOUBLE PRECISION** expression

#### **expression2**

The independent **DOUBLE PRECISION** expression

### Examples

```
=> SELECT REGR_R2 (Annual_salary, Employee_age) FROM employee_dimension;
 REGR_R2
```

```

5.17181631706311e-05
(1 row)
```

## REGR\_SLOPE

Returns the slope of the regression line, determined by a set of expression pairs. The return value is of type **DOUBLE PRECISION** . **REGR\_SLOPE** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR\_SLOPE** returns **NULL** .

### Syntax

```
SELECT REGR_SLOPE (expression1, expression2)
```

### Parameters

#### **expression1**

The dependent **DOUBLE PRECISION** expression

#### **expression2**

The independent **DOUBLE PRECISION** expression

### Examples

```
=> SELECT REGR_SLOPE (Annual_salary, Employee_age) FROM employee_dimension;
 REGR_SLOPE
```

```

-40.056400303749
(1 row)
```

## REGR\_SXX

Returns the sum of squares of the difference between the independent expression ( *expression2* ) and its average.

That is, **REGR\_SXX** returns:  $\sum[(\textit{expression2} - \text{average}(\textit{expression2}))(\textit{expression2} - \text{average}(\textit{expression2}))]$

The return value is of type **DOUBLE PRECISION** . **REGR\_SXX** eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, **REGR\_SXX** returns **NULL** .

### Syntax

```
SELECT REGR_SXX (expression1, expression2)
```

### Parameters

### **expression1**

The dependent **DOUBLE PRECISION** expression

### **expression2**

The independent **DOUBLE PRECISION** expression

### Examples

```
=> SELECT REGR_SXX (Annual_salary, Employee_age) FROM employee_dimension;
REGR_SXX

2254907.59
(1 row)
```

### REGR\_SXY

Returns the sum of products of the difference between the dependent expression ( *expression1* ) and its average and the difference between the independent expression ( *expression2* ) and its average.

That is, REGR\_SXY returns:  $\sum[(\textit{expression1} - \text{average}(\textit{expression1}))(\textit{expression2} - \text{average}(\textit{expression2}))]$

The return value is of type **DOUBLE PRECISION** . REGR\_SXY eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, REGR\_SXY returns **NULL** .

### Syntax

```
SELECT REGR_SXY (expression1, expression2)
```

### Parameters

#### **expression1**

The dependent **DOUBLE PRECISION** expression

#### **expression2**

The independent **DOUBLE PRECISION** expression

### Examples

```
=> SELECT REGR_SXY (Annual_salary, Employee_age) FROM employee_dimension;
REGR_SXY

-90323481.0730019
(1 row)
```

### REGR\_SYY

Returns the sum of squares of the difference between the dependent expression ( *expression1* ) and its average.

That is, REGR\_SYY returns:  $\sum[(\textit{expression1} - \text{average}(\textit{expression1}))(\textit{expression1} - \text{average}(\textit{expression1}))]$

The return value is of type **DOUBLE PRECISION** . REGR\_SYY eliminates expression pairs where either expression in the pair is **NULL** . If no rows remain, REGR\_SYY returns **NULL** .

### Syntax

```
SELECT REGR_SYY (expression1, expression2)
```

### Parameters

#### **expression1**

The dependent **DOUBLE PRECISION** expression

#### **expression2**

The independent **DOUBLE PRECISION** expression

### Examples

```
=> SELECT REGR_SYY (Annual_salary, Employee_age) FROM employee_dimension;
 REGR_SYY
```

```

69956728794707.2
```

```
(1 row)
```

STDDEV [aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of [VAR\\_SAMP](#) :

```
STDDEV(expression) = SQRT(VAR_SAMP(expression))
```

Behavior type

[Immutable](#)

Syntax

```
STDDEV (expression)
```

Parameters

***expression***

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **STDDEV** returns the same data type as *expression* .

Related functions

- Nonstandard function **STDDEV** is provided for compatibility with other databases. It is semantically identical to [STDDEV\\_SAMP](#) .
- This aggregate function differs from analytic function [STDDEV](#) , which computes the statistical sample standard deviation of the current row with respect to the group of rows within a [window](#) .
- When [VAR\\_SAMP](#) returns **NULL** , **STDDEV** returns **NULL** .

Examples

The following example returns the statistical sample standard deviation for each household ID from the [customer\\_dimension](#) table of the VMart example database:

```
=> SELECT STDDEV(household_id) FROM customer_dimension;
```

```
STDDEV
```

```

8651.5084240071
```

STDDEV\_POP [aggregate]

Evaluates the statistical population standard deviation for each member of the group.

Behavior type

[Immutable](#)

Syntax

```
STDDEV_POP (expression)
```

Parameters

***expression***

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **STDDEV\_POP** returns the same data type as *expression* .

Related functions

- This function differs from the analytic function [STDDEV\\_POP](#) , which evaluates the statistical population standard deviation for each member of the group of rows within a [window](#) .
- **STDDEV\_POP** returns the same value as the square root of [VAR\\_POP](#) :

```
STDDEV_POP(expression) = SQRT(VAR_POP(expression))
```

- When [VAR\\_SAMP](#) returns **NULL** , this function returns **NULL** .

Examples

The following example returns the statistical population standard deviation for each household ID in the [customer](#) table.

```
=> SELECT STDDEV_POP(household_id) FROM customer_dimension;
 STDDEV_POP
```

```

8651.41895973367
(1 row)
```

See also

- [Analytic functions](#)
- [SQL analytics](#)

STDDEV\_SAMP [aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of [VAR\\_SAMP](#):

```
STDDEV_SAMP(expression) = SQRT(VAR_SAMP(expression))
```

Behavior type

[Immutable](#)

Syntax

```
STDDEV_SAMP (expression)
```

Parameters

***expression***

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **STDDEV\_SAMP** returns the same data type as *expression*.

Related functions

- **STDDEV\_SAMP** is semantically identical to nonstandard function [STDDEV](#), which is provided for compatibility with other databases.
- This aggregate function differs from analytic function [STDDEV\\_SAMP](#), which computes the statistical sample standard deviation of the current row with respect to the group of rows within a [window](#).
- When [VAR\\_SAMP](#) returns **NULL**, **STDDEV\_SAMP** returns **NULL**.

Examples

The following example returns the statistical sample standard deviation for each household ID from the [customer](#) dimension table.

```
=> SELECT STDDEV_SAMP(household_id) FROM customer_dimension;
 stddev_samp
```

```

8651.50842400771
(1 row)
```

SUM [aggregate]

Computes the sum of an expression over a group of rows. **SUM** returns a **DOUBLE PRECISION** value for a floating-point expression. Otherwise, the return value is the same as the expression data type.

The **SUM** aggregate function differs from the [SUM](#) analytic function, which computes the sum of an expression over a group of rows within a [window](#).

Behavior type

[Immutable](#)

Syntax

```
SUM ([ALL | DISTINCT] expression)
```

Parameters

**ALL**

Invokes the aggregate function for all rows in the group (default)

**DISTINCT**

Invokes the aggregate function for all distinct non-null values of the expression found in the group

***expression***

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

## Overflow handling

If you encounter data overflow when using `SUM()`, use `SUM_FLOAT` which converts the data to a floating point.

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#).

## Examples

The following query returns the total sum of the `product_cost` column.

```
=> SELECT SUM(product_cost) AS cost FROM product_dimension;
cost

9042850
(1 row)
```

See also

- [AVG \[aggregate\]](#)
- [COUNT \[aggregate\]](#)

## SUM\_FLOAT [aggregate]

Computes the sum of an expression over a group of rows and returns a `DOUBLE PRECISION` value.

Behavior type

[Immutable](#)

Syntax

```
SUM_FLOAT ([ALL | DISTINCT] expression)
```

Parameters

### ALL

Invokes the aggregate function for all rows in the group (default).

### DISTINCT

Invokes the aggregate function for all distinct non-null values of the expression found in the group.

### *expression*

Any expression whose result is type `DOUBLE PRECISION`.

## Overflow handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#).

## Examples

The following query returns the floating-point sum of the average price from the product table:

```
=> SELECT SUM_FLOAT(average_competitor_price) AS cost FROM product_dimension;
cost

18181102
(1 row)
```

## TS\_FIRST\_VALUE

Processes the data that belongs to each time slice. A time series aggregate (TSA) function, `TS_FIRST_VALUE` returns the value at the start of the time slice, where an interpolation scheme is applied if the timeslice is missing, in which case the value is determined by the values corresponding to the previous (and next) timeslices based on the interpolation scheme of `const` (linear).

`TS_FIRST_VALUE` returns one output row per time slice, or one output row per partition per time slice if partition expressions are specified

Behavior type

[Immutable](#)

Syntax

```
TS_FIRST_VALUE (expression [IGNORE NULLS] [, { 'CONST' | 'LINEAR' }])
```

## Parameters

### **expression**

An **INTEGER** or **FLOAT** expression on which to aggregate and interpolate.

### **IGNORE NULLS**

The **IGNORE NULLS** behavior changes depending on a **CONST** or **LINEAR** interpolation scheme. See [When Time Series Data Contains Nulls](#) in *Analyzing Data* for details.

### **'CONST' | 'LINEAR'**

Specifies the interpolation value as constant or linear:

- **CONST** (default): New value is interpolated based on previous input records.
- **LINEAR**: Values are interpolated in a linear slope based on the specified time slice.

## Requirements

You must use an **ORDER BY** clause with a **TIMESTAMP** column.

## Multiple time series aggregate functions

The same query can call multiple time series aggregate functions. They share the same gap-filling policy as defined by the [TIMESERIES clause](#); however, each time series aggregate function can specify its own interpolation policy. For example:

```
=> SELECT slice_time, symbol,
TS_FIRST_VALUE(bid, 'const') fv_c,
 TS_FIRST_VALUE(bid, 'linear') fv_l,
 TS_LAST_VALUE(bid, 'const') lv_c
FROM TickStore
TIMESERIES slice_time AS '3 seconds'
OVER(PARTITION BY symbol ORDER BY ts);
```

## Examples

See [Gap Filling and Interpolation](#) in *Analyzing Data*.

## See also

- [TS\\_LAST\\_VALUE](#)
- [Time series analytics](#)

## TS\_LAST\_VALUE

Processes the data that belongs to each time slice. A time series aggregate (TSA) function, **TS\_LAST\_VALUE** returns the value at the end of the time slice, where an interpolation scheme is applied if the timeslice is missing. In this case the value is determined by the values corresponding to the previous (and next) timeslices based on the interpolation scheme of const (linear).

**TS\_LAST\_VALUE** returns one output row per time slice, or one output row per partition per time slice if partition expressions are specified.

## Behavior type

### [Immutable](#)

### Syntax

```
TS_LAST_VALUE (expression [IGNORE NULLS] [, { 'CONST' | 'LINEAR' }])
```

## Parameters

### **expression**

An **INTEGER** or **FLOAT** expression on which to aggregate and interpolate.

### **IGNORE NULLS**

The **IGNORE NULLS** behavior changes depending on a **CONST** or **LINEAR** interpolation scheme. See [When Time Series Data Contains Nulls](#) in *Analyzing Data* for details.

### **'CONST' | 'LINEAR'**

Specifies the interpolation value as constant or linear:

- **CONST** (default): New value is interpolated based on previous input records.
- **LINEAR**: Values are interpolated in a linear slope based on the specified time slice.

## Requirements

You must use the **ORDER BY** clause with a **TIMESTAMP** column.

## Multiple time series aggregate functions

The same query can call multiple time series aggregate functions. They share the same gap-filling policy as defined by the [TIMESERIES clause](#); however, each time series aggregate function can specify its own interpolation policy. For example:

```
=> SELECT slice_time, symbol,
TS_FIRST_VALUE(bid, 'const') fv_c,
 TS_FIRST_VALUE(bid, 'linear') fv_l,
 TS_LAST_VALUE(bid, 'const') lv_c
FROM TickStore
TIMESERIES slice_time AS '3 seconds'
OVER(PARTITION BY symbol ORDER BY ts);
```

### Examples

See [Gap Filling and Interpolation](#) in Analyzing Data.

See also

- [TS\\_FIRST\\_VALUE](#)
- [Time series analytics](#)

## VAR\_POP [aggregate]

Evaluates the population variance for each member of the group. This is defined as the sum of squares of the difference of \* **expression** \* from the mean of **expression** , divided by the number of remaining rows:

```
(SUM(expression*expression) - SUM(expression)*SUM(expression) / COUNT(expression)) / COUNT(expression)
```

### Behavior type

[Immutable](#)

### Syntax

```
VAR_POP (expression)
```

### Parameters

#### **expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **VAR\_POP** returns the same data type as **expression** .

### Related functions

This aggregate function differs from analytic function [VAR\\_POP](#) , which computes the population variance of the current row with respect to the group of rows within a [window](#) .

### Examples

The following example returns the population variance for each household ID in the **customer** table.

```
=> SELECT VAR_POP(household_id) FROM customer_dimension;
var_pop

74847050.0168393
(1 row)
```

## VAR\_SAMP [aggregate]

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of **expression** from the mean of **expression** divided by the number of remaining rows minus 1:

```
(SUM(expression*expression) - SUM(expression) *SUM(expression) / COUNT(expression)) / (COUNT(expression) -1)
```

### Behavior type

[Immutable](#)

### Syntax

```
VAR_SAMP (expression)
```

### Parameters

#### **expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **VAR\_SAMP** returns the same data type as *expression* .

#### Related functions

- **VAR\_SAMP** is semantically identical to nonstandard function [VARIANCE](#) , which is provided for compatibility with other databases.
- This aggregate function differs from analytic function [VAR\\_SAMP](#) , which computes the sample variance of the current row with respect to the group of rows within a [window](#) .

#### Examples

The following example returns the sample variance for each household ID in the **customer** table.

```
=> SELECT VAR_SAMP(household_id) FROM customer_dimension;
 var_samp

74848598.0106764
(1 row)
```

#### See also

[VARIANCE \[aggregate\]](#)

VARIANCE [aggregate]

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of *expression* from the mean of *expression* divided by the number of remaining rows minus 1.

```
(SUM(expression*expression) - SUM(expression) *SUM(expression) /COUNT(expression)) / (COUNT(expression) -1)
```

#### Behavior type

[Immutable](#)

#### Syntax

```
VARIANCE (expression)
```

#### Parameters

##### ***expression***

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. **VARIANCE** returns the same data type as *expression* .

#### Related functions

The nonstandard function **VARIANCE** is provided for compatibility with other databases. It is semantically identical to [VAR\\_SAMP](#) .

This aggregate function differs from analytic function [VARIANCE](#) , which computes the sample variance of the current row with respect to the group of rows within a [window](#) .

#### Examples

The following example returns the sample variance for each household ID in the **customer** table.

```
=> SELECT VARIANCE(household_id) FROM customer_dimension;
 variance

74848598.0106764
(1 row)
```

#### See also

- [Analytic functions](#)
- [VAR\\_SAMP \[aggregate\]](#)
- [SQL analytics](#)

#### WITHIN GROUP ORDER BY clause

Specifies how to sort rows that are grouped by aggregate functions, one of the following:

- [ARGMAX\\_AGG](#)
- [ARGMIN\\_AGG](#)
- [IMplode](#)
- [LISTAGG](#)

This clause is also supported for user-defined aggregate functions.

The order clause only specifies order within the result set of each group. The query can have its own [ORDER BY](#) clause, which has precedence over order that is specified by WITHIN GROUP ORDER BY, and orders the final result set.

#### Syntax

```
WITHIN GROUP (ORDER BY
 { column-expression [ASC | DESC [NULLS { FIRST | LAST | AUTO }]]
 }[,...])
```

#### Parameters

##### *column-expression*

A column, constant, or arbitrary expression formed on columns, on which to sort grouped rows.

##### **ASC | DESC**

Specifies the ordering sequence as ascending (default) or descending.

##### **NULLS {FIRST | LAST | AUTO}**

Specifies whether to position null values first or last. Default positioning depends on whether the sort order is ascending or descending:

- Ascending default: **NULLS LAST**
- Descending default: **NULLS FIRST**

If you specify **NULLS AUTO**, Vertica chooses the positioning that is most efficient for this query, either **NULLS FIRST** or **NULLS LAST**.

If you omit all sort qualifiers, Vertica uses **ASC NULLS LAST**.

#### Examples

For usage examples, see these functions:

- [ARGMAX\\_AGG](#)
- [ARGMIN\\_AGG](#)
- [IMPLODE](#)
- [LISTAGG](#)

#### Analytic functions

##### Note

All analytic functions in this section with an aggregate counterpart are appended with [Analytics] in the heading to avoid confusion between the two function types.

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window **ORDER BY** clause, but the order affects only the function result set, not the entire query result set.

#### Syntax

##### General

```
analytic-function(arguments) OVER(
 [window-partition-clause]
 [window-order-clause [window-frame-clause]]
)
```

##### With named window

```
analytic-function(arguments) OVER(
 [named-window [window-frame-clause]]
)
```

## Parameters

### **analytic-function ( arguments )**

A Vertica analytic function and its arguments.

### **OVER**

Specifies how to partition, sort, and window frame function input with respect to the current row. The input data is the result set that the query returns after it evaluates **FROM** , **WHERE** , **GROUP BY** , and **HAVING** clauses.

An empty **OVER** clause provides the best performance for single threaded queries on a single node.

### **[window-partition-clause](#)**

Groups input rows according to one or more columns or expressions.

If you omit this clause, no grouping occurs and the analytic function processes all input rows as a single partition.

### **[window-order-clause](#)**

Optionally specifies how to sort rows that are supplied to the analytic function. If the **OVER** clause also includes a partition clause, rows are sorted within each partition.

### **[window-frame-clause](#)**

Only valid for some analytic functions, specifies as input a set of rows relative to the row that is currently being evaluated by the analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly.

### **[named-window](#)**

The name of a window that you define in the same query with a [window-name-clause](#) . This definition encapsulates window partitioning and sorting. Named windows are useful when the query invokes multiple analytic functions with similar **OVER** clauses.

A window name clause cannot specify a window frame clause. However, you can qualify the named window in an **OVER** clause with a window frame clause.

## Requirements

The following requirements apply to analytic functions:

- All require an **OVER** clause. Each function has its own **OVER** clause requirements. For example, you can supply an empty **OVER** clause for some analytic aggregate functions such as **SUM** . For other functions, window frame and order clauses might be required, or might be invalid.
- Analytic functions can be invoked only in a query's **SELECT** and **ORDER BY** clauses.
- Analytic functions cannot be nested. For example, the following query is not allowed:  

```
=> SELECT MEDIAN(RANK() OVER(ORDER BY sal) OVER()).
```
- **WHERE** , **GROUP BY** and **HAVING** operators are technically not part of the analytic function. However, they determine input to that function.

#### ARGMAX [analytic]

This function is patterned after the mathematical function  $\operatorname{argmax}(f(x))$ , which returns the value of  $x$  that maximizes  $f(x)$ . Similarly, ARGMAX takes two arguments *target* and *arg*, where both are columns or column expressions in the queried dataset. ARGMAX finds the row with the largest non-null value in *target* and returns the value of *arg* in that row. If multiple rows contain the largest *target* value, ARGMAX returns *arg* from the first row that it finds.

#### Behavior type

[Immutable](#)

#### Syntax

```
ARGMAX (target, arg) OVER ([PARTITION BY expression[,...]] [window-order-clause])
```

#### Arguments

##### *target*, *arg*

Columns in the queried dataset.

#### Note

ARGMAX does not support [spatial data types](#): GEOMETRY and GEOGRAPHY.

#### OVER()

Specifies the following window clauses:

- **PARTITION BY *expression***: Groups (partitions) input rows according to the values in *expression*, which resolves to one or more columns in the queried dataset. If you omit this clause, ARGMAX processes all input rows as a single partition.
- **[window-order-clause](#)**: Specifies how to sort input rows. If the OVER clause also includes a partition clause, rows are sorted separately within each partition.

Important

To ensure consistent results when multiple rows contain the largest *target* value, include a window order clause that sorts on *arg*.

For details, see [Analytic Functions](#).

#### Examples

Create and populate table `service_info`, which contains information on various services, their respective development groups, and their userbase. A NULL in the `users` column indicates that the service has not been released, and so it cannot have users.

```

=> CREATE TABLE service_info(dev_group VARCHAR(10), product_name VARCHAR(30), users INT);
=> COPY t FROM stdin NULL AS 'null';
>> iris|chat|48193
>> aspen|trading|3000
>> orchid|cloud|990322
>> iris|video call| 10203
>> daffodil|streaming|44123
>> hydrangea|password manager|null
>> hydrangea|totp|1837363
>> daffodil|clip share|3000
>> hydrangea|e2e sms|null
>> rose|crypto|null
>> iris|forum|48193
>> \.

```

ARGMAX returns the value in the `product_name` column that maximizes the value in the `users` column. In this case, ARGMAX returns `totp`, which indicates that the `totp` service has the largest user base:

```

=> SELECT dev_group, product_name, users, ARGMAX(users, product_name) OVER (ORDER BY dev_group ASC) FROM service_info;
dev_group | product_name | users | ARGMAX
-----+-----+-----+-----
aspen | trading | 3000 | totp
daffodil | clip share | 3000 | totp
daffodil | streaming | 44123 | totp
hydrangea | e2e sms | | totp
hydrangea | password manager | | totp
hydrangea | totp | 1837363 | totp
iris | chat | 48193 | totp
iris | forum | 48193 | totp
iris | video call | 10203 | totp
orchid | cloud | 990322 | totp
rose | crypto | | totp
(11 rows)

```

The next query partitions the data on `dev_group` to identify the most popular service created by each development group. ARGMAX returns NULL if the partition's `users` column contains only NULL values and breaks ties using the first value in `product_name` from the top of the partition.

```

=> SELECT dev_group, product_name, users, ARGMAX(users, product_name) OVER (PARTITION BY dev_group ORDER BY product_name ASC) FROM
service_info;
dev_group | product_name | users | ARGMAX
-----+-----+-----+-----
iris | chat | 48193 | chat
iris | forum | 48193 | chat
iris | video call | 10203 | chat
orchid | cloud | 990322 | cloud
aspen | trading | 3000 | trading
daffodil | clip share | 3000 | streaming
daffodil | streaming | 44123 | streaming
rose | crypto | |
hydrangea | e2e sms | | totp
hydrangea | password manager | | totp
hydrangea | totp | 1837363 | totp
(11 rows)

```

See also

[ARGMIN \[analytic\]](#)

ARGMIN [analytic]

This function is patterned after the mathematical function `argmin( f( x ) )`, which returns the value of `x` that minimizes `f( x )`. Similarly, ARGMIN takes two arguments `target` and `arg`, where both are columns or column expressions in the queried dataset. ARGMIN finds the row with the smallest non-null value in `target` and returns the value of `arg` in that row. If multiple rows contain the smallest `target` value, ARGMIN returns `arg` from the first row that it finds.

Behavior type

[Immutable](#)

Syntax

```
ARGMIN (target, arg) OVER ([PARTITION BY expression[,...]] [window-order-clause])
```

Arguments

**target , arg**

Columns in the queried dataset.

#### Note

ARGMIN does not support [spatial data types](#): GEOMETRY and GEOGRAPHY.

## OVER()

Specifies the following window clauses:

- **PARTITION BY expression**: Groups (partitions) input rows according to the values in `expression`, which resolves to one or more columns in the queried dataset. If you omit this clause, ARGMIN processes all input rows as a single partition.
- **window-order-clause**: Specifies how to sort input rows. If the **OVER** clause also includes a partition clause, rows are sorted separately within each partition.

Important

To ensure consistent results when multiple rows contain the smallest `target` value, include a window order clause that sorts on `arg`.

For details, see [Analytic Functions](#).

Examples

Create and populate table `service_info`, which contains information on various services, their respective development groups, and their userbase. A NULL in the `users` column indicates that the service has not been released, and so it cannot have users.

```
=> CREATE TABLE service_info(dev_group VARCHAR(10), product_name VARCHAR(30), users INT);
=> COPY t FROM stdin NULL AS 'null';
>> iris|chat|48193
>> aspen|trading|3000
>> orchid|cloud|990322
>> iris|video call| 10203
>> daffodil|streaming|44123
>> hydrangea|password manager|null
>> hydrangea|totp|1837363
>> daffodil|clip share|3000
>> hydrangea|e2e sms|null
>> rose|crypto|null
>> iris|forum|48193
>> \.
```

ARGMIN returns the value in the `product_name` column that minimizes the value in the `users` column. In this case, ARGMIN returns `totp`, which indicates that the `totp` service has the smallest user base:

```
=> SELECT dev_group, product_name, users, ARGMIN(users, product_name) OVER (ORDER BY dev_group ASC) FROM service_info;
dev_group | product_name | users | ARGMIN
-----+-----+-----+-----
aspen | trading | 3000 | trading
daffodil | clip share | 3000 | trading
daffodil | streaming | 44123 | trading
hydrangea | e2e sms | | trading
hydrangea | password manager | | trading
hydrangea | totp | 1837363 | trading
iris | chat | 48193 | trading
iris | forum | 48193 | trading
iris | video call | 10203 | trading
orchid | cloud | 990322 | trading
rose | crypto | | trading
(11 rows)
```

The next query partitions the data on `dev_group` to identify the least popular service created by each development group. ARGMIN returns NULL if the partition's `users` column contains only NULL values and breaks ties using the first value in `product_name` from the top of the partition.

```
=> SELECT dev_group, product_name, users, ARGMIN(users, product_name) OVER (PARTITION BY dev_group ORDER BY product_name ASC) FROM
service_info;
dev_group | product_name | users | ARGMIN
-----+-----+-----+-----
iris | chat | 48193 | video call
iris | forum | 48193 | video call
iris | video call | 10203 | video call
orchid | cloud | 990322 | cloud
aspen | trading | 3000 | trading
daffodil | clip share | 3000 | clip share
daffodil | streaming | 44123 | clip share
rose | crypto | |
hydrangea | e2e sms | | totp
hydrangea | password manager | | totp
hydrangea | totp | 1837363 | totp
(11 rows)
```

See also

[ARGMAX \[analytic\]](#)

[AVG \[analytic\]](#)

Computes an average of an expression in a group within a [window](#). `AVG` returns the same data type as the expression's numeric data type.

The `AVG` analytic function differs from the `AVG` aggregate function, which computes the average of an expression over a group of rows.

Behavior type

[Immutable](#)

Syntax

```
AVG (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

Parameters

***expression***

Any data that can be implicitly converted to a numeric data type.

**OVER()**

See [Analytic Functions](#).

Overflow handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#).

## Examples

The following query finds the sales for that calendar month and returns a running/cumulative average (sometimes called a moving average) using the default window of **RANGE UNBOUNDED PRECEDING AND CURRENT ROW**:

```
=> SELECT calendar_month_number_in_year Mo, SUM(product_price) Sales,
 AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year)::INTEGER Average
 FROM product_dimension pd, date_dimension dm, inventory_fact if
 WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key GROUP BY Mo;
Mo | Sales | Average
-----+-----+-----
 1 | 23869547 | 23869547
 2 | 19604661 | 21737104
 3 | 22877913 | 22117374
 4 | 22901263 | 22313346
 5 | 23670676 | 22584812
 6 | 22507600 | 22571943
 7 | 21514089 | 22420821
 8 | 24860684 | 22725804
 9 | 21687795 | 22610470
10 | 23648921 | 22714315
11 | 21115910 | 22569005
12 | 24708317 | 22747281
(12 rows)
```

To return a moving average that is not a running (cumulative) average, the window can specify **ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING**:

```
=> SELECT calendar_month_number_in_year Mo, SUM(product_price) Sales,
 AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year
 ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING)::INTEGER Average
 FROM product_dimension pd, date_dimension dm, inventory_fact if
 WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key GROUP BY Mo;
Mo | Sales | Average
-----+-----+-----
 1 | 23869547 | 22117374
 2 | 19604661 | 22313346
 3 | 22877913 | 22584812
 4 | 22901263 | 22312423
 5 | 23670676 | 22694308
 6 | 22507600 | 23090862
 7 | 21514089 | 22848169
 8 | 24860684 | 22843818
 9 | 21687795 | 22565480
10 | 23648921 | 23204325
11 | 21115910 | 22790236
12 | 24708317 | 23157716
(12 rows)
```

See also

- [COUNT \[analytic\]](#)
- [SUM \[analytic\]](#)
- [SQL analytics](#)

**BOOL\_AND** [analytic]

Returns the Boolean value of an expression within a [window](#). If all input values are true, **BOOL\_AND** returns **t**. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
BOOL_AND (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

Parameters

***expression***

A [Boolean data type](#) or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.

**OVER()**

See [Analytic Functions](#).

Examples

The following example illustrates how you can use the **BOOL\_AND** , **BOOL\_OR** , and **BOOL\_XOR** analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT

 10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 ( **BOOL\_AND** ), once or twice in 2014 ( **BOOL\_OR** ), and specifically not more than once in 2014 ( **BOOL\_XOR** ).

```
=> SELECT DISTINCT emptytype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidjustoncein2014
FROM employee;
```

emptytype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

(5 rows)

- [BOOL\\_XOR \[analytic\]](#)
- [Boolean data type](#)

**BOOL\_OR** [analytic]

Returns the Boolean value of an expression within a [window](#). If at least one input value is true, **BOOL\_OR** returns **t**. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
BOOL_OR (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

Parameters

***expression***

A [Boolean data type](#) or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.

**OVER()**

See [Analytic Functions](#).

Examples

The following example illustrates how you can use the **BOOL\_AND**, **BOOL\_OR**, and **BOOL\_XOR** analytic functions. The sample table, `employee`, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT

 10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 ( [BOOL\\_AND](#) ), once or twice in 2014 ( [BOOL\\_OR](#) ), and specifically not more than once in 2014 ( [BOOL\\_XOR](#) ).

```
=> SELECT DISTINCT emptype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidjustoncein2014
FROM employee;
```

emptype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

- [BOOL\\_XOR \[analytic\]](#)
- [Boolean data type](#)

[BOOL\\_XOR \[analytic\]](#)

Returns the Boolean value of an expression within a [window](#). If only one input value is true, [BOOL\\_XOR](#) returns [t](#). Otherwise, it returns [f](#).

Behavior type

[Immutable](#)

Syntax

```
BOOL_XOR (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

## Parameters

### **expression**

A [Boolean data type](#) or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.

## **OVER()**

See [Analytic Functions](#).

## Examples

The following example illustrates how you can use the **BOOL\_AND** , **BOOL\_OR** , and **BOOL\_XOR** analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT
```

```

 10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 ( **BOOL\_AND** ), once or twice in 2014 ( **BOOL\_OR** ), and specifically not more than once in 2014 ( **BOOL\_XOR** ).

```
=> SELECT DISTINCT emptytype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptytype) AS paidjustoncein2014
FROM employee;
```

```
emptytype | paidtwicein2014 | paidonceortwicein2014 | paidjustoncein2014
-----+-----+-----+-----
contractor1 | t | t | f
contractor2 | f | t | t
contractor3 | f | t | t
contractor4 | t | t | f
contractor5 | f | f | f
(5 rows)
```

## See also

CONDITIONAL\_CHANGE\_EVENT [analytic]

Assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row.

Behavior type

[Immutable](#)

Syntax

```
CONDITIONAL_CHANGE_EVENT (expression) OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

**expression**

SQL scalar expression that is evaluated on an input record. The result of \* **expression** \* can be of any data type.

**OVER()**

See [Analytic Functions](#).

Notes

The analytic [window-order-clause](#) is required but the [window-partition-clause](#) is optional.

Examples

```
=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
 OVER (PARTITION BY symbol ORDER BY ts) AS cce
FROM TickStore;
```

The system returns an error when no **ORDER BY** clause is present:

```
=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
 OVER (PARTITION BY symbol) AS cce
FROM TickStore;
```

ERROR: conditional\_change\_event must contain an ORDER BY clause within its analytic clause

For more examples, see [Event-based windows](#).

See also

- [CONDITIONAL\\_TRUE\\_EVENT \[analytic\]](#)
- [ROW\\_NUMBER \[analytic\]](#)
- [Time series analytics](#)
- [Event-based windows](#)

CONDITIONAL\_TRUE\_EVENT [analytic]

Assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true. For example, given a sequence of values for column a, as follows:

```
(1, 2, 3, 4, 5, 6)
```

**CONDITIONAL\_TRUE\_EVENT(a > 3)** returns 0, 0, 0, 1, 2, 3 .

Behavior type

[Immutable](#)

Syntax

```
CONDITIONAL_TRUE_EVENT (boolean-expression) OVER (
 [window-partition-clause]
 window-order-clause)
```

## Parameters

### **boolean-expression**

SQL scalar expression that is evaluated on an input record, type BOOLEAN.

### **OVER()**

See [Analytic functions](#).

## Notes

The analytic *window-order-clause* is required but the *window-partition-clause* is optional.

## Examples

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
 OVER(PARTITION BY bid ORDER BY ts) AS cte
FROM Tickstore;
```

The system returns an error if the **ORDER BY** clause is omitted:

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
 OVER(PARTITION BY bid) AS cte
FROM Tickstore;
```

ERROR: conditional\_true\_event must contain an ORDER BY clause within its analytic clause

For more examples, see [Event-based windows](#).

## See also

- [CONDITIONAL\\_CHANGE\\_EVENT \[analytic\]](#)
- [Time series analytics](#)
- [Event-based windows](#)

## COUNT [analytic]

Counts occurrences within a group within a [window](#). If you specify \* or some non-null constant, **COUNT()** counts all rows.

## Behavior type

### [Immutable](#)

## Syntax

```
COUNT (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

## Parameters

### **expression**

Returns the number of rows in each group for which the *expression* is not null. Can be any expression resulting in BIGINT.

### **OVER()**

See [Analytic Functions](#).

## Examples

Using the schema defined in [Window framing](#), the following **COUNT** function omits window order and window frame clauses; otherwise Vertica would treat it as a window aggregate. Think of the window of reporting aggregates as **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW**.

```
=> SELECT deptno, sal, empno, COUNT(sal)
 OVER (PARTITION BY deptno) AS count FROM emp;
```

```
deptno | sal | empno | count
```

```
-----+-----+-----+-----
10 | 101 | 1 | 2
10 | 104 | 4 | 2
20 | 110 | 10 | 6
20 | 110 | 9 | 6
20 | 109 | 7 | 6
20 | 109 | 6 | 6
20 | 109 | 8 | 6
20 | 109 | 11 | 6
30 | 105 | 5 | 3
30 | 103 | 3 | 3
30 | 102 | 2 | 3
```

Using **ORDER BY sal** creates a moving window query with default window: **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW** .

```
=> SELECT deptno, sal, empno, COUNT(sal)
 OVER (PARTITION BY deptno ORDER BY sal) AS count
 FROM emp;
```

```
deptno | sal | empno | count
```

```
-----+-----+-----+-----
10 | 101 | 1 | 1
10 | 104 | 4 | 2
20 | 100 | 11 | 1
20 | 109 | 7 | 4
20 | 109 | 6 | 4
20 | 109 | 8 | 4
20 | 110 | 10 | 6
20 | 110 | 9 | 6
30 | 102 | 2 | 1
30 | 103 | 3 | 2
30 | 105 | 5 | 3
```

Using the VMart schema, the following query finds the number of employees who make less than or equivalent to the hourly rate of the current employee. The query returns a running/cumulative average (sometimes called a moving average) using the default window of **RANGE UNBOUNDED PRECEDING AND CURRENT ROW** :

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)
 OVER (ORDER BY hourly_rate) AS moving_count from employee_dimension;
```

```
last_name | hourly_rate | moving_count
```

```
-----+-----+-----
Gauthier | 6 | 4
Taylor | 6 | 4
Jefferson | 6 | 4
Nielson | 6 | 4
McNulty | 6.01 | 11
Robinson | 6.01 | 11
Dobisz | 6.01 | 11
Williams | 6.01 | 11
Kramer | 6.01 | 11
Miller | 6.01 | 11
Wilson | 6.01 | 11
Vogel | 6.02 | 14
Moore | 6.02 | 14
Vogel | 6.02 | 14
Carcetti | 6.03 | 19
...
```

To return a moving average that is not also a running (cumulative) average, the window should specify **ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING** :

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)
 OVER (ORDER BY hourly_rate ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING)
 AS moving_count from employee_dimension;
```

See also

- [COUNT \[aggregate\]](#)
- [AVG \[analytic\]](#)
- [SUM \[analytic\]](#)
- [SQL analytics](#)

CUME\_DIST [analytic]

Calculates the cumulative distribution, or relative rank, of the current row with regard to other rows in the same partition within a [window](#).

**CUME\_DIST()** returns a number greater than 0 and less than or equal to 1, where the number represents the relative position of the specified row within a group of *n* rows. For a row *x* (assuming **ASC** ordering), the **CUME\_DIST** of *x* is the number of rows with values lower than or equal to the value of *x*, divided by the number of rows in the partition. For example, in a group of three rows, the cumulative distribution values returned would be 1/3, 2/3, and 3/3.

#### Note

Because the result for a given row depends on the number of rows preceding that row in the same partition, you should always specify a **window-order-clause** when you call this function.

Behavior type

[Immutable](#)

Syntax

```
CUME_DIST () OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

**OVER()**

See [Analytic Functions](#).

Examples

The following example returns the cumulative distribution of sales for different transaction types within each month of the first quarter.

```
=> SELECT calendar_month_name AS month, tender_type, SUM(sales_quantity),
 CUME_DIST()
 OVER (PARTITION BY calendar_month_name ORDER BY SUM(sales_quantity)) AS
CUME_DIST
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January','February','March')
AND tender_type NOT LIKE 'Other'
GROUP BY calendar_month_name, tender_type;
```

month	tender_type	SUM	CUME_DIST
March	Credit	469858	0.25
March	Cash	470449	0.5
March	Check	473033	0.75
March	Debit	475103	1
January	Cash	441730	0.25
January	Debit	443922	0.5
January	Check	446297	0.75
January	Credit	450994	1
February	Check	425665	0.25
February	Debit	426726	0.5
February	Credit	430010	0.75
February	Cash	430767	1

(12 rows)

- [PERCENT\\_RANK \[analytic\]](#)
- [PERCENTILE\\_DISC \[analytic\]](#)
- [SQL analytics](#)

DENSE\_RANK [analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's **ORDER BY** clause. A **DENSE\_RANK** function returns a sequence of ranking numbers without any gaps.

**DENSE\_RANK** executes as follows:

1. Sorts partition rows as specified by the **ORDER BY** clause.
2. Compares the **ORDER BY** values of the preceding row and current row and ranks the current row as follows:
  - If **ORDER BY** values are the same, the current row gets the same ranking as the preceding row.

#### Note

Null values are considered equal. For detailed information on how null values are sorted, see [NULL sort order](#).

- If the **ORDER BY** values are different, **DENSE\_RANK** increments or decrements the current row's ranking by 1, depending whether sort order is ascending or descending.

**DENSE\_RANK** always changes the ranking by 1, so no gaps appear in the ranking sequence. The largest rank value is the number of unique **ORDER BY** values returned by the query.

Behavior type

[Immutable](#)

Syntax

```
DENSE_RANK() OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

## OVER()

See [Analytic Functions](#).

See [Analytic Functions](#)

Compared with RANK

[RANK](#) leaves gaps in the ranking sequence, while [DENSE\\_RANK](#) does not. The example below compares the behavior of the two functions.

Examples

The following query invokes [RANK](#) and [DENSE\\_RANK](#) to rank customers by annual income. The two functions return different rankings, as follows:

- If [annual\\_salary](#) contains duplicate values, [RANK\(\)](#) inserts duplicate rankings and then skips one or more values—for example, from 4 to 6 and 7 to 9.
- In the parallel column [Dense Rank](#), [DENSE\\_RANK\(\)](#) also inserts duplicate rankings, but leaves no gaps in the rankings sequence:

```
=> SELECT employee_region region, employee_key, annual_salary,
RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) Rank,
DENSE_RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) "Dense Rank"
FROM employee_dimension;
```

region	employee_key	annual_salary	Rank	Dense Rank
West	5248	1200	1	1
West	6880	1204	2	2
West	5700	1214	3	3
West	9857	1218	4	4
West	6014	1218	4	4
West	9221	1220	6	5
West	7646	1222	7	6
West	6621	1222	7	6
West	6488	1224	9	7
West	7659	1226	10	8
West	7432	1226	10	8
West	9905	1226	10	8
West	9021	1228	13	9
...				
West	56	963104	2794	2152
West	100	992363	2795	2153
East	8353	1200	1	1
East	9743	1202	2	2
East	9975	1202	2	2
East	9205	1204	4	3
East	8894	1206	5	4
East	7740	1206	5	4
East	7324	1208	7	5
East	6505	1208	7	5
East	5404	1208	7	5
East	5010	1208	7	5
East	9114	1212	11	6
...				

See also

[SQL analytics](#)

EXPONENTIAL\_MOVING\_AVERAGE [analytic]

Calculates the exponential moving average (EMA) of expression *E* with smoothing factor *X*. An EMA differs from a simple moving average in that it provides a more stable picture of changes to data over time.

The EMA is calculated by adding the previous EMA value to the current data point scaled by the smoothing factor, as in the following formula:

$$EMA = EMA0 + ( X * ( E - EMA0 ) )$$

where:

- *E* is the current data point
- *EMA0* is the previous row's EMA value.
- *X* is the smoothing factor.

This function also works at the row level. For example, EMA assumes the data in a given column is sampled at uniform intervals. If the users' data points are sampled at non-uniform intervals, they should run the time series [gap filling and interpolation \(GFI\)](#) operations before EMA()

Behavior type

[Immutable](#)

Syntax

```
EXPONENTIAL_MOVING_AVERAGE (E, X) OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

**E**

The value whose average is calculated over a set of rows. Can be **INTEGER** , **FLOAT** or **NUMERIC** type and must be a constant.

**X**

A positive **FLOAT** value between 0 and 1 that is used as the smoothing factor.

**OVER()**

See [Analytic Functions](#).

Examples

The following example uses time series [gap filling and interpolation](#) (GFI) first in a subquery, and then performs an **EXPONENTIAL\_MOVING\_AVERAGE** operation on the subquery result.

Create a simple four-column table:

```
=> CREATE TABLE ticker(
 time TIMESTAMP,
 symbol VARCHAR(8),
 bid1 FLOAT,
 bid2 FLOAT);
```

Insert some data, including nulls, so GFI can do its interpolation and gap filling:

```
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'ABC', 60.45, 60.44);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'ABC', 60.49, 65.12);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'ABC', 57.78, 59.25);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'ABC', null, 65.12);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'ABC', 67.88, null);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'XYZ', 47.55, 40.15);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'XYZ', 44.35, 46.78);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'XYZ', 71.56, 75.78);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'XYZ', 85.55, 70.21);
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'XYZ', 45.55, 58.65);
=> COMMIT;
```

#### Note

During gap filling and interpolation, Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and you do not specify **IGNORE NULLS** , and your data has one real value and one null, the result is null. If the value on either side is null, the result is null. See [When Time Series Data Contains Nulls](#) for details.

Query the table that you just created to you can see the output:

```
=> SELECT * FROM ticker;
 time | symbol | bid1 | bid2
-----+-----+-----+-----
2009-07-12 03:00:00 | ABC | 60.45 | 60.44
2009-07-12 03:00:01 | ABC | 60.49 | 65.12
2009-07-12 03:00:02 | ABC | 57.78 | 59.25
2009-07-12 03:00:03 | ABC | | 65.12
2009-07-12 03:00:04 | ABC | 67.88 |
2009-07-12 03:00:00 | XYZ | 47.55 | 40.15
2009-07-12 03:00:01 | XYZ | 44.35 | 46.78
2009-07-12 03:00:02 | XYZ | 71.56 | 75.78
2009-07-12 03:00:03 | XYZ | 85.55 | 70.21
2009-07-12 03:00:04 | XYZ | 45.55 | 58.65
(10 rows)
```

The following query processes the first and last values that belong to each 2-second time slice in table `trades` ' column `a` . The query then calculates the exponential moving average of expression `fv` and `lv` with a smoothing factor of 50%:

```
=> SELECT symbol, slice_time, fv, lv,
 EXponential_Moving_Average(fv, 0.5)
 OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_first,
 EXponential_Moving_Average(lv, 0.5)
 OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_last
FROM (
 SELECT symbol, slice_time,
 TS_FIRST_VALUE(bid1 IGNORE NULLS) as fv,
 TS_LAST_VALUE(bid2 IGNORE NULLS) AS lv
 FROM ticker TIMESERIES slice_time AS '2 seconds'
 OVER (PARTITION BY symbol ORDER BY time) AS sq;
```

```
symbol | slice_time | fv | lv | ema_first | ema_last
-----+-----+-----+-----+-----+-----
ABC | 2009-07-12 03:00:00 | 60.45 | 65.12 | 60.45 | 65.12
ABC | 2009-07-12 03:00:02 | 57.78 | 65.12 | 59.115 | 65.12
ABC | 2009-07-12 03:00:04 | 67.88 | 65.12 | 63.4975 | 65.12
XYZ | 2009-07-12 03:00:00 | 47.55 | 46.78 | 47.55 | 46.78
XYZ | 2009-07-12 03:00:02 | 71.56 | 70.21 | 59.555 | 58.495
XYZ | 2009-07-12 03:00:04 | 45.55 | 58.65 | 52.5525 | 58.5725
(6 rows)
```

#### FIRST\_VALUE [analytic]

Lets you select the first value of a table or partition (determined by the *window-order-clause* ) without having to use a self join. This function is useful when you want to use the first value as a baseline in calculations.

Use `FIRST_VALUE()` with the *window-order-clause* to produce deterministic results. If no *window* is specified for the current row, the default window is **UNBOUNDED PRECEDING AND CURRENT ROW** .

Behavior type

[Immutable](#)

Syntax

```
FIRST_VALUE (expression [IGNORE NULLS]) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

## Parameters

### **expression**

Expression to evaluate—or example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.

### **IGNORE NULLS**

Specifies to return the first non-null value in the set, or **NULL** if all values are **NULL**. If you omit this option and the first value in the set is null, the function returns **NULL**.

### **OVER()**

See [Analytic Functions](#).

## Examples

The following query asks for the first value in the partitioned day of week, and illustrates the potential nondeterministic nature of **FIRST\_VALUE()**:

```
=> SELECT calendar_year, date_key, day_of_week, full_date_description,
FIRST_VALUE(full_date_description)
OVER(PARTITION BY calendar_month_number_in_year ORDER BY day_of_week)
AS "first_value"
FROM date_dimension
WHERE calendar_year=2003 AND calendar_month_number_in_year=1;
```

The first value returned is January 31, 2003; however, the next time the same query is run, the first value might be January 24 or January 3, or the 10th or 17th. This is because the analytic **ORDER BY** column **day\_of\_week** returns rows that contain ties (multiple Fridays). These repeated values make the **ORDER BY** evaluation result nondeterministic, because rows that contain ties can be ordered in any way, and any one of those rows qualifies as being the first value of **day\_of\_week**.

calendar_year	date_key	day_of_week	full_date_description	first_value
2003	31	Friday	January 31, 2003	January 31, 2003
2003	24	Friday	January 24, 2003	January 31, 2003
2003	3	Friday	January 3, 2003	January 31, 2003
2003	10	Friday	January 10, 2003	January 31, 2003
2003	17	Friday	January 17, 2003	January 31, 2003
2003	6	Monday	January 6, 2003	January 31, 2003
2003	27	Monday	January 27, 2003	January 31, 2003
2003	13	Monday	January 13, 2003	January 31, 2003
2003	20	Monday	January 20, 2003	January 31, 2003
2003	11	Saturday	January 11, 2003	January 31, 2003
2003	18	Saturday	January 18, 2003	January 31, 2003
2003	25	Saturday	January 25, 2003	January 31, 2003
2003	4	Saturday	January 4, 2003	January 31, 2003
2003	12	Sunday	January 12, 2003	January 31, 2003
2003	26	Sunday	January 26, 2003	January 31, 2003
2003	5	Sunday	January 5, 2003	January 31, 2003
2003	19	Sunday	January 19, 2003	January 31, 2003
2003	23	Thursday	January 23, 2003	January 31, 2003
2003	2	Thursday	January 2, 2003	January 31, 2003
2003	9	Thursday	January 9, 2003	January 31, 2003
2003	16	Thursday	January 16, 2003	January 31, 2003
2003	30	Thursday	January 30, 2003	January 31, 2003
2003	21	Tuesday	January 21, 2003	January 31, 2003
2003	14	Tuesday	January 14, 2003	January 31, 2003
2003	7	Tuesday	January 7, 2003	January 31, 2003
2003	28	Tuesday	January 28, 2003	January 31, 2003
2003	22	Wednesday	January 22, 2003	January 31, 2003
2003	29	Wednesday	January 29, 2003	January 31, 2003
2003	15	Wednesday	January 15, 2003	January 31, 2003
2003	1	Wednesday	January 1, 2003	January 31, 2003
2003	8	Wednesday	January 8, 2003	January 31, 2003

(31 rows)

The `day_of_week` results are returned in alphabetical order because of lexical rules. The fact that each day does not appear ordered by the 7-day week cycle (for example, starting with Sunday followed by Monday, Tuesday, and so on) has no effect on results.

To return deterministic results, modify the query so that it performs its analytic `ORDER BY` operations on a **unique** field, such as `date_key` :

```
=> SELECT calendar_year, date_key, day_of_week, full_date_description,
 FIRST_VALUE(full_date_description) OVER
 (PARTITION BY calendar_month_number_in_year ORDER BY date_key) AS "first_value"
FROM date_dimension WHERE calendar_year=2003;
```

`FIRST_VALUE()` returns a first value of January 1 for the January partition and the first value of February 1 for the February partition. Also, the `full_date_description` column contains no ties:

calendar_year	date_key	day_of_week	full_date_description	first_value
2003	1	Wednesday	January 1, 2003	January 1, 2003
2003	2	Thursday	January 2, 2003	January 1, 2003
2003	3	Friday	January 3, 2003	January 1, 2003
2003	4	Saturday	January 4, 2003	January 1, 2003
2003	5	Sunday	January 5, 2003	January 1, 2003
2003	6	Monday	January 6, 2003	January 1, 2003
2003	7	Tuesday	January 7, 2003	January 1, 2003
2003	8	Wednesday	January 8, 2003	January 1, 2003
2003	9	Thursday	January 9, 2003	January 1, 2003
2003	10	Friday	January 10, 2003	January 1, 2003
2003	11	Saturday	January 11, 2003	January 1, 2003
2003	12	Sunday	January 12, 2003	January 1, 2003

2003	32	Saturday	February 1, 2003	February 1, 2003
2003	33	Sunday	February 2, 2003	February 1, 2003
...				

(365 rows)

See also

- [LAST\\_VALUE \[analytic\]](#)
- [TIME\\_SLICE](#)
- [SQL analytics](#)

[LAG \[analytic\]](#)

Returns the value of the input expression at the given offset before the current row within a [window](#). This function lets you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

For information on getting the rows that follow, see [LEAD](#).

Behavior type

[Immutable](#)

Syntax

```
LAG (expression[, offset] [, default]) OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

**expression**

The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.

**offset**

Indicates how great is the lag. The default value is 1 (the previous row). This parameter must evaluate to a constant positive integer.

**default**

The value returned if *offset* falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first argument.

Examples

This example sums the current balance by date in a table and also sums the previous balance from the last day. Given the inputs that follow, the data satisfies the following conditions:

- For each *some\_id*, there is exactly 1 row for each date represented by *month\_date*.
- For each *some\_id*, the set of dates is consecutive; that is, if there is a row for February 24 and a row for February 26, there would also be a row for February 25.
- Each *some\_id* has the same set of dates.

```
=> CREATE TABLE balances (
 month_date DATE,
 current_bal INT,
 some_id INT);
=> INSERT INTO balances values ('2009-02-24', 10, 1);
=> INSERT INTO balances values ('2009-02-25', 10, 1);
=> INSERT INTO balances values ('2009-02-26', 10, 1);
=> INSERT INTO balances values ('2009-02-24', 20, 2);
=> INSERT INTO balances values ('2009-02-25', 20, 2);
=> INSERT INTO balances values ('2009-02-26', 20, 2);
=> INSERT INTO balances values ('2009-02-24', 30, 3);
=> INSERT INTO balances values ('2009-02-25', 20, 3);
=> INSERT INTO balances values ('2009-02-26', 30, 3);
```

Now run LAG to sum the current balance for each date and sum the previous balance from the last day:

```
=> SELECT month_date,
 SUM(current_bal) as current_bal_sum,
 SUM(previous_bal) as previous_bal_sum FROM
 (SELECT month_date, current_bal,
 LAG(current_bal, 1, 0) OVER
 (PARTITION BY some_id ORDER BY month_date)
 AS previous_bal FROM balances) AS subQ
 GROUP BY month_date ORDER BY month_date;
```

month_date	current_bal_sum	previous_bal_sum
2009-02-24	60	0
2009-02-25	50	60
2009-02-26	60	50

(3 rows)

Using the same example data, the following query would not be allowed because LAG is nested inside an aggregate function:

```
=> SELECT month_date,
 SUM(current_bal) as current_bal_sum,
 SUM(LAG(current_bal, 1, 0) OVER
 (PARTITION BY some_id ORDER BY month_date)) AS previous_bal_sum
 FROM some_table GROUP BY month_date ORDER BY month_date;
```

The following example uses the [VMart database](#). LAG first returns the annual income from the previous row, and then it calculates the difference between the income in the current row from the income in the previous row:

```
=> SELECT occupation, customer_key, customer_name, annual_income,
 LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
 ORDER BY annual_income) AS prev_income, annual_income -
 LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
 ORDER BY annual_income) AS difference
 FROM customer_dimension ORDER BY occupation, customer_key LIMIT 20;
```

occupation	customer_key	customer_name	annual_income	prev_income	difference
Accountant	15	Midori V. Peterson	692610	692535	75
Accountant	43	Midori S. Rodriguez	282359	280976	1383

(20 rows)

The next example uses [LEAD](#) and LAG to return the third row after the salary in the current row and fifth salary before the salary in the current row:

```
=> SELECT hire_date, employee_key, employee_last_name,
 LEAD(hire_date, 1) OVER (ORDER BY hire_date) AS "next_hired" ,
 LAG(hire_date, 1) OVER (ORDER BY hire_date) AS "last_hired"
 FROM employee_dimension ORDER BY hire_date, employee_key;
```

hire_date	employee_key	employee_last_name	next_hired	last_hired
1956-04-11	2694	Farmer	1956-05-12	
1956-05-12	5486	Winkler	1956-09-18	1956-04-11

## LAST\_VALUE [analytic]

Lets you select the last value of a table or partition (determined by the *window-order-clause* ) without having to use a self join. **LAST\_VALUE** takes the last record from the partition after the window order clause. The function then computes the expression against the last record, and returns the results. This function is useful when you want to use the last value as a baseline in calculations.

Use **LAST\_VALUE()** with the *window-order-clause* to produce deterministic results. If no [window](#) is specified for the current row, the default window is **UNBOUNDED PRECEDING AND CURRENT ROW** .

### Tip

Due to default window semantics, **LAST\_VALUE** does not always return the last value of a partition. If you omit *window-frame-clause* from the analytic clause, **LAST\_VALUE** operates on this default window. Although results can seem non-intuitive by not returning the bottom of the current partition, it returns the bottom of the window, which continues to change along with the current input row being processed. If you want to return the last value of a partition, use **UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING** . See examples below.

## Behavior type

[Immutable](#)

## Syntax

```
LAST_VALUE (expression [IGNORE NULLS]) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

## Parameters

### **expression**

Expression to evaluate—for example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.

### **IGNORE NULLS**

Specifies to return the last non-null value in the set, or **NULL** if all values are **NULL** . If you omit this option and the last value in the set is null, the function returns **NULL** .

### **OVER()**

See [Analytic Functions](#).

## Examples

Using the schema defined in [Window framing](#) in Analyzing Data, the following query does not show the highest salary value by department; instead it shows the highest salary value by department by salary.

```
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
 OVER (PARTITION BY deptno ORDER BY sal) AS lv
FROM emp;
deptno | sal | empno | lv
-----+-----+-----+-----
 10 | 101 | 1 | 101
 10 | 104 | 4 | 104
 20 | 100 | 11 | 100
 20 | 109 | 7 | 109
 20 | 109 | 6 | 109
 20 | 109 | 8 | 109
 20 | 110 | 10 | 110
 20 | 110 | 9 | 110
 30 | 102 | 2 | 102
 30 | 103 | 3 | 103
 30 | 105 | 5 | 105
```

If you include the window frame clause **ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING** , **LAST\_VALUE()** returns the highest salary by department, an accurate representation of the information:

```
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
 OVER (PARTITION BY deptno ORDER BY sal
 ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
deptno | sal | empno | lv
-----+-----+-----+----
10 | 101 | 1 | 104
10 | 104 | 4 | 104
20 | 100 | 11 | 110
20 | 109 | 7 | 110
20 | 109 | 6 | 110
20 | 109 | 8 | 110
20 | 110 | 10 | 110
20 | 110 | 9 | 110
30 | 102 | 2 | 105
30 | 103 | 3 | 105
30 | 105 | 5 | 105
```

For more examples, see [FIRST\\_VALUE\(\)](#).

See also

- [FIRST\\_VALUE \[analytic\]](#)
- [TIME\\_SLICE](#)
- [SQL analytics](#)

LEAD [analytic]

Returns values from the row after the current row within a [window](#), letting you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

Behavior type

[Immutable](#)

Syntax

```
LEAD (expression [, offset] [, default]) OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

***expression***

The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.

***offset***

Is an optional parameter that defaults to 1 (the next row). This parameter must evaluate to a constant positive integer.

***default***

The value returned if *offset* falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first argument.

Examples

**LEAD** finds the hire date of the employee hired just after the current row:

```
=> SELECT employee_region, hire_date, employee_key, employee_last_name,
 LEAD(hire_date, 1) OVER (PARTITION BY employee_region ORDER BY hire_date) AS "next_hired"
 FROM employee_dimension ORDER BY employee_region, hire_date, employee_key;
employee_region | hire_date | employee_key | employee_last_name | next_hired
```

```
-----+-----+-----+-----+-----

MAX [analytic]

Returns the maximum value of an expression within a [window](#). The return value has the same type as the expression data type.

The analytic functions [MIN\(\)](#) and [MAX\(\)](#) can operate with Boolean values. The [MAX\(\)](#) function acts upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean value. If at least one input value is true, [MAX\(\)](#) returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, the [MIN\(\)](#) function returns **t** (true) if all input values are true. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
MAX (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

Parameters

***expression***

Any expression for which the maximum value is calculated, typically a [column reference](#).

**OVER()**

See [Analytic Functions](#).

Examples

The following query computes the deviation between the employees' annual salary and the maximum annual salary in Massachusetts:

```
=> SELECT employee_state, annual_salary,
 MAX(annual_salary)
 OVER(PARTITION BY employee_state ORDER BY employee_key) max,
 annual_salary- MAX(annual_salary)
 OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
employee_state | annual_salary | max | diff
-----+-----+-----+-----
MA | 1918 | 995533 | -993615
MA | 2058 | 995533 | -993475
MA | 2586 | 995533 | -992947
MA | 2500 | 995533 | -993033
MA | 1318 | 995533 | -994215
MA | 2072 | 995533 | -993461
MA | 2656 | 995533 | -992877
MA | 2148 | 995533 | -993385
MA | 2366 | 995533 | -993167
MA | 2664 | 995533 | -992869
(10 rows)
```

The following example shows you the difference between the **MIN** and **MAX** analytic functions when you use them with a Boolean value. The sample creates a table with two columns, adds two rows of data, and shows sample output for **MIN** and **MAX**.

```
CREATE TABLE min_max_functions (emp VARCHAR, torf BOOL);

INSERT INTO min_max_functions VALUES ('emp1', 1);
INSERT INTO min_max_functions VALUES ('emp1', 0);

SELECT DISTINCT emp,
min(torf) OVER (PARTITION BY emp) AS worksasbooleanand,
Max(torf) OVER (PARTITION BY emp) AS worksasbooleanor
FROM min_max_functions;

emp | worksasbooleanand | worksasbooleanor
-----+-----+-----
emp1 | f | t
(1 row)
```

See also

- [SQL analytics](#)
- [MAX \[aggregate\]](#)
- [MIN \[analytic\]](#)

**MEDIAN** [analytic]

For each row, returns the median value of a value set within each partition. **MEDIAN** determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

**MEDIAN** is an alias of [PERCENTILE\\_CONT \[analytic\]](#) with an argument of 0.5 (50%).

Behavior type

[Immutable](#)

Syntax

```
MEDIAN (expression) OVER ([window-partition-clause])
```

Parameters

***expression***

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the middle value or an interpolated value that would be the middle value once the values are sorted. Null values are ignored in the calculation.

**OVER()**

If the **OVER** clause specifies *window-partition-clause*, **MEDIAN** groups input rows according to one or more columns or expressions. If this clause is omitted, no grouping occurs and **MEDIAN** processes all input rows as a single partition.

Examples

See [Calculating a median value](#)

See also

- [PERCENTILE\\_CONT \[analytic\]](#)
- [SQL analytics](#)

MIN [analytic]

Returns the minimum value of an expression within a [window](#). The return value has the same type as the expression data type.

The analytic functions **MIN()** and **MAX()** can operate with Boolean values. The **MAX()** function acts upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean value. If at least one input value is true, **MAX()** returns **t** (true). Otherwise, it returns **f** (false). In the same scenario, the **MIN()** function returns **t** (true) if all input values are true. Otherwise, it returns **f**.

Behavior type

[Immutable](#)

Syntax

```
MIN (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

Parameters

**expression**

Any expression for which the minimum value is calculated, typically a [column reference](#).

**OVER()**

See [Analytic Functions](#).

Examples

The following example shows how you can query to determine the deviation between the employees' annual salary and the minimum annual salary in Massachusetts:

```
=> SELECT employee_state, annual_salary,
 MIN(annual_salary)
 OVER(PARTITION BY employee_state ORDER BY employee_key) min,
 annual_salary- MIN(annual_salary)
 OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
employee_state | annual_salary | min | diff
```

```
-----+-----+-----+-----
MA | 1918 | 1204 | 714
MA | 2058 | 1204 | 854
MA | 2586 | 1204 | 1382
MA | 2500 | 1204 | 1296
MA | 1318 | 1204 | 114
MA | 2072 | 1204 | 868
MA | 2656 | 1204 | 1452
MA | 2148 | 1204 | 944
MA | 2366 | 1204 | 1162
MA | 2664 | 1204 | 1460
```

(10 rows)

The following example shows you the difference between the **MIN** and **MAX** analytic functions when you use them with a Boolean value. The sample creates a table with two columns, adds two rows of data, and shows sample output for **MIN** and **MAX**.

```
CREATE TABLE min_max_functions (emp VARCHAR, torf BOOL);
```

```
INSERT INTO min_max_functions VALUES ('emp1', 1);
```

```
INSERT INTO min_max_functions VALUES ('emp1', 0);
```

```
SELECT DISTINCT emp,
min(torf) OVER (PARTITION BY emp) AS worksasbooleanand,
Max(torf) OVER (PARTITION BY emp) AS worksasbooleanor
FROM min_max_functions;
```

```
emp | worksasbooleanand | worksasbooleanor
```

```
-----+-----+-----
emp1 | f | t
```

```
(1 row)
```

See also

- [SQL analytics](#)
- [MIN \[aggregate\]](#)
- [MAX \[analytic\]](#)

NTH\_VALUE [analytic]

Returns the value evaluated at the row that is the \* *n* \*th row of the window (counting from 1). If the specified row does not exist, NTH\_VALUE returns **NULL** .

Behavior type

[Immutable](#)

Syntax

```
NTH_VALUE (expression, row-number [IGNORE NULLS]) OVER (
 [window-frame-clause]
 [window-order-clause])
```

Parameters

***expression***

Expression to evaluate. The expression can be a constant, column name, nonanalytic function, function expression, or expressions that include any of these.

***row-number***

Specifies the row to evaluate, where *row-number* evaluates to an integer  $\geq 1$ .

**IGNORE NULLS**

Specifies to return the first non- **NULL** value in the set, or **NULL** if all values are **NULL** .

**OVER()**

See [Analytic Functions](#).

Examples

In the following example, for each tuple (current row) in table **t1** , the window frame clause defines the window as follows:

```
ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW
```

For each window, *n* for \* *n* \*th value is **a+1** . *a* is the value of column *a* in the tuple.

NTH\_VALUE returns the result of the expression **b+1** , where *b* is the value of column *b* in the \* *n* \*th row, which is the **a+1** row within the window.

```
=> SELECT * FROM t1 ORDER BY a;
```

```
a | b
---+---
1 | 10
2 | 20
2 | 21
3 | 30
4 | 40
5 | 50
6 | 60
(7 rows)
```

```
=> SELECT NTH_VALUE(b+1, a+1) OVER
 (ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW) FROM t1;
?column?
```

```

 22
 31

(7 rows)
```

NTILE [analytic]

Equally divides an ordered data set (partition) into a { *value* } number of subsets within a [window](#), where the subsets are numbered 1 through the value in parameter *constant-value*. For example, if *constant-value* = 4 and the partition contains 20 rows, **NTILE** divides the partition rows into four equal subsets of five rows. **NTILE** assigns each row to a subset by giving row a number from 1 to 4. The rows in the first subset are assigned 1, the next five are assigned 2, and so on.

If the number of partition rows is not evenly divisible by the number of subsets, the rows are distributed so no subset is more than one row larger than any other subset, and the lowest subsets have extra rows. For example, if *constant-value* = 4 and the number of rows = 21, the first subset has six rows, the second subset has five rows, and so on.

If the number of subsets is greater than the number of rows, then a number of subsets equal to the number of rows is filled, and the remaining subsets are empty.

Behavior type

[Immutable](#)

Syntax

```
NTILE (constant-value) OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

***constant-value***

Specifies the number of subsets, where *constant-value* must resolve to a positive constant for each partition.

**OVER()**

See [Analytic Functions](#).

Examples

The following query assigns each month's sales total into one of four subsets:

```
=> SELECT calendar_month_name AS MONTH, SUM(sales_quantity),
 NTILE(4) OVER (ORDER BY SUM(sales_quantity)) AS NTILE
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
GROUP BY calendar_month_name
ORDER BY NTILE;
MONTH | SUM | NTILE
```

```
-----+-----+-----
November | 2040726 | 1
June | 2088528 | 1
February | 2134708 | 1
April | 2181767 | 2
January | 2229220 | 2
October | 2316363 | 2
September | 2323914 | 3
March | 2354409 | 3
August | 2387017 | 3
July | 2417239 | 4
May | 2492182 | 4
December | 2531842 | 4
(12 rows)
```

See also

- [PERCENTILE\\_CONT \[analytic\]](#)
- [WIDTH\\_BUCKET](#)
- [SQL analytics](#)

PERCENT\_RANK [analytic]

Calculates the relative rank of a row for a given row in a group within a [window](#) by dividing that row's rank less 1 by the number of rows in the partition, also less 1. **PERCENT\_RANK** always returns values from 0 to 1 inclusive. The first row in any set has a **PERCENT\_RANK** of 0. The return value is **NUMBER** .

$$(\text{rank} - 1) / ([\text{rows}] - 1)$$

In the preceding formula, **rank** is the rank position of a row in the group and **rows** is the total number of rows in the partition defined by the **OVER()** clause.

Behavior type

[Immutable](#)

Syntax

```
PERCENT_RANK () OVER (
 [window-partition-clause]
 window-order-clause)
```

Parameters

**OVER()**

See [Analytic Functions](#)

Examples

The following example finds the percent rank of gross profit for different states within each month of the first quarter:

```
=> SELECT calendar_month_name AS MONTH, store_state,
 SUM(gross_profit_dollar_amount),
 PERCENT_RANK() OVER (PARTITION BY calendar_month_name
 ORDER BY SUM(gross_profit_dollar_amount)) AS PERCENT_RANK
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
JOIN store.store_dimension
USING (store_key)
WHERE calendar_month_name IN ('January','February','March')
AND store_state IN ('OR','IA','DC','NV','WI')
GROUP BY calendar_month_name, store_state
ORDER BY calendar_month_name, PERCENT_RANK;
MONTH | store_state | SUM | PERCENT_RANK
```

```
-----+-----+-----+-----
February | IA | 418490 | 0
February | OR | 460588 | 0.25
February | DC | 616553 | 0.5
February | WI | 619204 | 0.75
February | NV | 838039 | 1
January | OR | 446528 | 0
January | IA | 474501 | 0.25
January | DC | 628496 | 0.5
January | WI | 679382 | 0.75
January | NV | 871824 | 1
March | IA | 460282 | 0
March | OR | 481935 | 0.25
March | DC | 716063 | 0.5
March | WI | 771575 | 0.75
March | NV | 970878 | 1
(15 rows)
```

The following example calculates, for each employee, the percent rank of the employee's salary by their job title:

```
=> SELECT job_title, employee_last_name, annual_salary,
 PERCENT_RANK()
 OVER (PARTITION BY job_title ORDER BY annual_salary DESC) AS percent_rank
FROM employee_dimension
ORDER BY percent_rank, annual_salary;
 job_title | employee_last_name | annual_salary | percent_rank
```

#### PERCENTILE\_CONT [analytic]

An inverse distribution function where, for each row, PERCENTILE\_CONT returns the value that would fall into the specified percentile among a set of values in each partition within a [window](#). For example, if the argument to the function is 0.5, the result of the function is the median of the data set (50th percentile). PERCENTILE\_CONT assumes a continuous distribution data model. NULL values are ignored.

PERCENTILE\_CONT computes the percentile by first computing the row number where the percentile row would exist. For example:

$$row-number = 1 + percentile-value * (num-partition-rows - 1)$$

If *row-number* is a whole number (within an error of 0.00001), the percentile is the value of row *row-number*.

Otherwise, Vertica interpolates the percentile value between the value of the `CEILING( row-number )` row and the value of the `FLOOR( row-number )` row. In other words, the percentile is calculated as follows:

$$( CEILING( row-number ) - row-number ) * ( value\ of\ FLOOR(row-number)\ row ) \\ + ( row-number - FLOOR(row-number) ) * ( value\ of\ CEILING(row-number)\ row )$$

## Note

If the percentile value is 0.5, PERCENTILE\_CONT returns the same result set as the function [MEDIAN](#).

Behavior type

[Immutable](#)

Syntax

```
PERCENTILE_CONT (percentile) WITHIN GROUP (ORDER BY expression [ASC | DESC]) OVER ([window-partition-clause])
```

Parameters

### *percentile*

Percentile value, a FLOAT constant that ranges from 0 to 1 (inclusive).

### **WITHIN GROUP (ORDER BY *expression* )**

Specifies how to sort data within each group. ORDER BY takes only one column/expression that must be INTEGER, FLOAT, INTERVAL, or NUMERIC data type. NULL values are discarded.

The **WITHIN GROUP(ORDER BY)** clause does not guarantee the order of the SQL result. To order the final result, use the SQL [ORDER BY](#) clause set.

### **ASC | DESC**

Specifies the ordering sequence as ascending (default) or descending.

Specifying ASC or DESC in the **WITHIN GROUP** clause affects results as long as the *percentile* is not **0.5**.

### **OVER()**

See [Analytic Functions](#)

Examples

This query computes the median annual income per group for the first 300 customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income, PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY annual_income)
 OVER (PARTITION BY customer_state) AS PERCENTILE_CONT
 FROM customer_dimension WHERE customer_state IN ('DC','WI') AND customer_key < 300
 ORDER BY customer_state, customer_key;
customer_state | customer_key | annual_income | PERCENTILE_CONT
-----+-----+-----+-----
DC | 52 | 168312 | 483266.5
DC | 118 | 798221 | 483266.5
WI | 62 | 283043 | 377691
WI | 139 | 472339 | 377691
(4 rows)
```

This query computes the median annual income per group for all customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income, PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY annual_income)
 OVER (PARTITION BY customer_state) AS PERCENTILE_CONT
 FROM customer_dimension WHERE customer_state IN ('DC','WI') ORDER BY customer_state, customer_key;
customer_state | customer_key | annual_income | PERCENTILE_CONT
```

```
-----+-----+-----+-----
DC | 52 | 168312 | 483266.5
DC | 118 | 798221 | 483266.5
DC | 622 | 220782 | 555088
DC | 951 | 178453 | 555088
DC | 972 | 961582 | 555088
DC | 1286 | 760445 | 555088
DC | 1434 | 44836 | 555088
```

...

```
WI | 62 | 283043 | 377691

WI | 403 | 509031 | 517717
WI | 455 | 32000 | 517717
WI | 485 | 373129 | 517717
```

...

(1353 rows)

See also

- [MEDIAN \[analytic\]](#)
- [SQL analytics](#)

PERCENTILE\_DISC [analytic]

An inverse distribution function where, for each row, **PERCENTILE\_DISC** returns the value that would fall into the specified percentile among a set of values in each partition within a [window](#). **PERCENTILE\_DISC()** assumes a discrete distribution data model. **NULL** values are ignored.

**PERCENTILE\_DISC** examines the cumulative distribution values in each group until it finds one that is greater than or equal to the specified percentile. Vertica computes the percentile where, for each row, **PERCENTILE\_DISC** outputs the first value of the **WITHIN GROUP(ORDER BY)** column whose **CUME\_DIST** (cumulative distribution) value is  $\geq$  the argument **FLOAT** value—for example, **0.4** :

```
PERCENTILE_DIST(0.4) WITHIN GROUP (ORDER BY salary) OVER(PARTITION BY deptno)...
```

Given the following query:

```
SELECT CUME_DIST() OVER(ORDER BY salary) FROM table-name;
```

The smallest **CUME\_DIST** value that is greater than 0.4 is also the **PERCENTILE\_DISC** .

Behavior type

[Immutable](#)

Syntax

```
PERCENTILE_DISC (percentile) WITHIN GROUP (
 ORDER BY expression [ASC | DESC]) OVER (
 [window-partition-clause])
```

Parameters

**percentile**

Percentile value, a **FLOAT** constant that ranges from 0 to 1 (inclusive).

**WITHIN GROUP(ORDER BY *expression* )**

Specifies how to sort data within each group. **ORDER BY** takes only one column/expression that must be **INTEGER** , **FLOAT** , **INTERVAL** , or **NUMERIC** data type. **NULL** values are discarded.

The **WITHIN GROUP(ORDER BY)** clause does not guarantee the order of the SQL result. To order the final result , use the SQL [ORDER BY](#) clause set.

## ASC | DESC

Specifies the ordering sequence as ascending (default) or descending.

## OVER()

See [Analytic Functions](#)

### Examples

This query computes the 20th percentile annual income by group for first 300 customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income,
 PERCENTILE_DISC(.2) WITHIN GROUP(ORDER BY annual_income)
 OVER (PARTITION BY customer_state) AS PERCENTILE_DISC
FROM customer_dimension
WHERE customer_state IN ('DC','WI')
AND customer_key < 300
ORDER BY customer_state, customer_key;
customer_state | customer_key | annual_income | PERCENTILE_DISC
-----+-----+-----+-----
DC | 104 | 658383 | 417092
DC | 168 | 417092 | 417092
DC | 245 | 670205 | 417092
WI | 106 | 227279 | 227279
WI | 127 | 703889 | 227279
WI | 209 | 458607 | 227279
(6 rows)
```

See also

- [CUME\\_DIST \[analytic\]](#)
- [PERCENTILE\\_CONT \[analytic\]](#)
- [SQL analytics](#)

## RANK [analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's **ORDER BY** clause.

**RANK** executes as follows:

1. Sorts partition rows as specified by the **ORDER BY** clause.
2. Compares the **ORDER BY** values of the preceding row and current row and ranks the current row as follows:
  - If **ORDER BY** values are the same, the current row gets the same ranking as the preceding row.

### Note

Null values are considered equal. For detailed information on how null values are sorted, see [NULL sort order](#).

- If the **ORDER BY** values are different, **DENSE\_RANK** increments or decrements the current row's ranking by 1, plus the number of consecutive duplicate values in the rows that precede it.

The largest rank value is the equal to the total number of rows returned by the query.

### Behavior type

[Immutable](#)

### Syntax

```
RANK() OVER (
 [window-partition-clause]
 window-order-clause)
```

### Parameters

## OVER()

See [Analytic Functions](#)

Compared with **DENSE\_RANK**

**RANK** can leave gaps in the ranking sequence, while [DENSE\\_RANK](#) does not.

### Examples

The following query ranks by state all company customers that have been customers since 2007. In rows where the `customer_since` dates are the same, **RANK** assigns the rows equal ranking. When the `customer_since` date changes, **RANK** skips one or more rankings—for example, within **CA**, from 12 to 14, and from 17 to 19.

```
=> SELECT customer_state, customer_name, customer_since,
 RANK() OVER (PARTITION BY customer_state ORDER BY customer_since) AS rank
FROM customer_dimension WHERE customer_type='Company' AND customer_since > '01/01/2007'
ORDER BY customer_state;
customer_state | customer_name | customer_since | rank

See also

[SQL analytics](#)

`ROW_NUMBER` [analytic]

Assigns a sequence of unique numbers to each row in a [window](#) partition, starting with 1. `ROW_NUMBER` and [RANK](#) are generally interchangeable, with the following differences:

- `ROW_NUMBER` assigns a unique ordinal number to each row in the ordered set, starting with 1.
- `ROW_NUMBER()` is a Vertica extension, while `RANK` conforms to the SQL-99 standard.

Behavior type

[Immutable](#)

Syntax

```
ROW_NUMBER () OVER (
 [window-partition-clause]
 [window-order-clause])
```

Parameters

**OVER()**

See [Analytic Functions](#)

### Examples

The following `ROW_NUMBER` query partitions customers in the VMart table `customer_dimension` by `customer_region`. Within each partition, the function ranks those customers in order of seniority, as specified by its window order clause:

```
=> SELECT * FROM
 (SELECT ROW_NUMBER() OVER (PARTITION BY customer_region ORDER BY customer_since) AS most_senior,
 customer_region, customer_name, customer_since FROM public.customer_dimension WHERE customer_type = 'Individual') sq
 WHERE most_senior <= 5;
```

```
most_senior | customer_region | customer_name | customer_since
```

```

- [RANK \[analytic\]](#)
- [SQL analytics](#)

STDDEV [analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a [window](#). **STDDEV\_SAMP** returns the same value as the square root of the variance defined for the [VAR\\_SAMP](#) function:

```
STDDEV(expression) = SQRT(VAR_SAMP(expression))
```

When **VAR\_SAMP** returns **NULL**, this function returns **NULL**.

#### Note

The nonstandard function **STDDEV** is provided for compatibility with other databases. It is semantically identical to [STDDEV\\_SAMP](#).

Behavior type

[Immutable](#)

Syntax

```
STDDEV (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

#### Parameters

##### **expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

##### **OVER()**

See [Analytic Functions](#)

#### Examples

The following example returns the standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
 STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev"
FROM employee_dimension
WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev

#### STDDEV\_POP [analytic]

Computes the statistical population standard deviation and returns the square root of the population variance within a [window](#). The `STDDEV_POP()` return value is the same as the square root of the `VAR_POP()` function:

```
STDDEV_POP(expression) = SQRT(VAR_POP(expression))
```

When `VAR_POP` returns null, `STDDEV_POP` returns null.

#### Behavior type

[Immutable](#)

#### Syntax

```
STDDEV_POP (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

#### Parameters

##### **expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

##### **OVER()**

See [Analytic Functions](#).

#### Examples

The following example returns the population standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
 STDDEV_POP(annual_salary) OVER (ORDER BY hire_date) as "stddev_pop"
FROM employee_dimension WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev_pop

#### STDDEV\_SAMP [analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a [window](#). **STDDEV\_SAMP**'s return value is the same as the square root of the variance defined for the **VAR\_SAMP** function:

```
STDDEV(expression) = SQRT(VAR_SAMP(expression))
```

When **VAR\_SAMP** returns **NULL**, **STDDEV\_SAMP** returns **NULL**.

#### Note

**STDDEV\_SAMP()** is semantically identical to the nonstandard function, [STDDEV\(\)](#).

#### Behavior type

[Immutable](#)

#### Syntax

```
STDDEV_SAMP (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

#### Parameters

##### **expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument..

## OVER()

See [Analytic Functions](#)

### Examples

The following example returns the sample standard deviations of salaries in the `employee` dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
 STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev_samp"
 FROM employee_dimension WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev_samp
-----+-----+-----
Bauer | 85003 | NaN
Reyes | 91051 | 4276.58181261624
Overstreet | 53296 | 20278.6923394976
Gauthier | 97216 | 19543.7184537642
Jones | 82320 | 16928.0764028285

- [STDDEV\\_SAMP \[aggregate\]](#)
- [SQL analytics](#)

## SUM [analytic]

Computes the sum of an expression over a group of rows within a [window](#). It returns a `DOUBLE PRECISION` value for a floating-point expression. Otherwise, the return value is the same as the expression data type.

### Behavior type

[Immutable](#)

### Syntax

```
SUM (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

### Parameters

#### **expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

## OVER()

See [Analytic Functions](#)

### Overflow handling

If you encounter data overflow when using `SUM`, use [SUM\\_FLOAT](#) which converts data to a floating point.

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric data type overflow with SUM, SUM\\_FLOAT, and AVG](#).

### Examples

The following query returns the cumulative sum all of the returns made to stores in January:

```
=> SELECT calendar_month_name AS month, transaction_type, sales_quantity,
SUM(sales_quantity)
OVER (PARTITION BY calendar_month_name ORDER BY date_dimension.date_key) AS SUM
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January')
AND transaction_type= 'return';
month | transaction_type | sales_quantity | SUM
-----+-----+-----+-----
January | return | 7 | 651
January | return | 3 | 651
January | return | 7 | 651
January | return | 7 | 651
January | return | 7 | 651
January | return | 3 | 651
January | return | 7 | 651
January | return | 5 | 651
January | return | 1 | 651
January | return | 6 | 651
January | return | 6 | 651
January | return | 3 | 651
January | return | 9 | 651
January | return | 7 | 651
January | return | 6 | 651
January | return | 8 | 651
January | return | 7 | 651
January | return | 2 | 651
January | return | 4 | 651
January | return | 5 | 651
January | return | 7 | 651
January | return | 8 | 651
January | return | 4 | 651
January | return | 10 | 651
January | return | 6 | 651
...
```

See also

- [SUM \[aggregate\]](#)
- [Numeric data types](#)
- [SQL analytics](#)

VAR\_POP [analytic]

Returns the statistical population variance of a non-null set of numbers (nulls are ignored) in a group within a [window](#). Results are calculated by the sum of squares of the difference of *expression* from the mean of *expression*, divided by the number of rows remaining:

$$\frac{(\text{SUM}( expression * expression ) - \text{SUM}( expression ) * \text{SUM}( expression ) / \text{COUNT}( expression ))}{\text{COUNT}( expression )}$$

Behavior type

[Immutable](#)

Syntax

```
VAR_POP (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

Parameters

**expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument

## OVER()

See [Analytic Functions](#)

### Examples

The following example calculates the cumulative population in the store orders fact table of sales in January 2007:

```
=> SELECT date_ordered,
 VAR_POP(SUM(total_order_cost))
 OVER (ORDER BY date_ordered) "var_pop"
FROM store.store_orders_fact s
WHERE date_ordered BETWEEN '2007-01-01' AND '2007-01-31'
GROUP BY s.date_ordered;
date_ordered | var_pop
-----+-----
2007-01-01 | 0
2007-01-02 | 89870400
2007-01-03 | 3470302472
2007-01-04 | 4466755450.6875
2007-01-05 | 3816904780.80078
2007-01-06 | 25438212385.25
2007-01-07 | 22168747513.1016
2007-01-08 | 23445191012.7344
2007-01-09 | 39292879603.1113
2007-01-10 | 48080574326.9609
(10 rows)
```

See also

- [VAR\\_POP \[aggregate\]](#)
- [SQL analytics](#)

### VAR\_SAMP [analytic]

Returns the sample variance of a non- **NULL** set of numbers ( **NULL** values in the set are ignored) for each row of the group within a [window](#) . Results are calculated as follows:

$$\frac{(\text{SUM}( expression * expression ) - \text{SUM}( expression ) * \text{SUM}( expression ) / \text{COUNT}( expression ) )}{(\text{COUNT}( expression ) - 1)}$$

This function and [VARIANCE](#) differ in one way: given an input set of one element, **VARIANCE** returns 0 and **VAR\_SAMP** returns **NULL** .

### Behavior type

[Immutable](#)

### Syntax

```
VAR_SAMP (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

### Parameters

#### **expression**

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument

## OVER()

See [Analytic Functions](#)

### Null handling

- **VAR\_SAMP** returns the sample variance of a set of numbers after it discards the **NULL** values in the set.
- If the function is applied to an empty set, then it returns **NULL** .

### Examples

The following example calculates the sample variance in the store orders fact table of sales in December 2007:

```
=> SELECT date_ordered,
 VAR_SAMP(SUM(total_order_cost))
 OVER (ORDER BY date_ordered) "var_samp"
FROM store.store_orders_facts
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31'
GROUP BY s.date_ordered;
date_ordered | var_samp
```

```
-----+-----
2007-12-01 | NaN
2007-12-02 | 90642601088
2007-12-03 | 48030548449.3359
2007-12-04 | 32740062504.2461
2007-12-05 | 32100319112.6992
2007-12-06 | 26274166814.668
2007-12-07 | 23017490251.9062
2007-12-08 | 21099374085.1406
2007-12-09 | 27462205977.9453
2007-12-10 | 26288687564.1758
(10 rows)
```

See also

- [VARIANCE \[analytic\]](#)
- [VAR\\_SAMP \[aggregate\]](#)
- [SQL analytics](#)

VARIANCE [analytic]

Returns the sample variance of a non- **NULL** set of numbers ( **NULL** values in the set are ignored) for each row of the group within a [window](#). Results are calculated as follows:

$$\frac{(\text{SUM}( expression * expression ) - \text{SUM}( expression ) * \text{SUM}( expression ) / \text{COUNT}( expression ))}{(\text{COUNT}( expression ) - 1)}$$

**VARIANCE** returns the variance of *expression*, which is calculated as follows:

- 0 if the number of rows in *expression* = 1
- [VAR\\_SAMP](#) if the number of rows in *expression* > 1

#### Note

The nonstandard function **VARIANCE** is provided for compatibility with other databases. It is semantically identical to [VAR\\_SAMP](#).

Behavior type

[Immutable](#)

Syntax

```
VAR_SAMP (expression) OVER (
 [window-partition-clause]
 [window-order-clause]
 [window-frame-clause])
```

Parameters

#### *expression*

Any [NUMERIC data type](#) or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

#### OVER()

See [Analytic Functions](#)

Examples

The following example calculates the cumulative variance in the store orders fact table of sales in December 2007:

```
=> SELECT date_ordered,
 VARIANCE(SUM(total_order_cost))
 OVER (ORDER BY date_ordered) "variance"
FROM store.store_orders_facts
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31'
GROUP BY s.date_ordered;
date_ordered | variance
```

```
-----+-----
2007-12-01 | NaN
2007-12-02 | 2259129762

## Client connection functions

This section contains client connection management functions specific to Vertica.

In this section

- [CLOSE\\_ALL\\_RESULTSETS](#)
- [CLOSE\\_RESULTSET](#)
- [DESCRIBE\\_LOAD\\_BALANCE\\_DECISION](#)
- [GET\\_CLIENT\\_LABEL](#)
- [RESET\\_LOAD\\_BALANCE\\_POLICY](#)
- [SET\\_CLIENT\\_LABEL](#)
- [SET\\_LOAD\\_BALANCE\\_POLICY](#)

## CLOSE\_ALL\_RESULTSETS

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SELECT CLOSE_ALL_RESULTSETS ('session_id')
```

Parameters

### **session\_id**

A string that specifies the Multiple Active Result Sets session.

Privileges

None; however, without superuser privileges, you can only close your own session's results.

Examples

This example shows how you can view a MARS result set, then close the result set, and then confirm that the result set has been closed.

Query the MARS storage table. One session ID is open and three result sets appear in the output.

```
=> SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	7	777460	776460	89692848
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	8	324349	323349	81862010
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	9	277947	276947	32978280

(1 row)

Close all result sets for session server1.company.-83046:1y28gu9:

```
=> SELECT CLOSE_ALL_RESULTSETS('server1.company.-83046:1y28gu9');
 close_all_resultsets
```

-----  
Closing all result sets from server1.company.-83046:1y28gu9  
(1 row)

Query the MARS storage table again for the current status. You can see that the session and result sets have been closed:

```
=> SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
-----------	------------	-----------	--------------	-----------	---------------------	------------

(0 rows)

## CLOSE\_RESULTSET

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SELECT CLOSE_RESULTSET ('session_id', ResultSetID)
```

Parameters

### **session\_id**

A string that specifies the Multiple Active Result Sets session containing the ResultSetID to close.

### **ResultSetID**

An integer that specifies which result set to close.

Privileges

None; however, without superuser privileges, you can only close your own session's results.

Examples

This example shows a MARS storage table opened. One session\_id is currently open, and one result set appears in the output.

```
=> SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	1	318718	312718	80441904

(1 row)

Close user session server1.company.-83046:1y28gu9 and result set 1:

```
=> SELECT CLOSE_RESULTSET('server1.company.-83046:1y28gu9', 1);
 close_resultset
```

-----  
Closing result set 1 from server1.company.-83046:1y28gu9  
(1 row)

Query the MARS storage table again for current status. You can see that result set 1 is now closed:

```
SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
(0 rows)						

## DESCRIBE\_LOAD\_BALANCE\_DECISION

Evaluates if any load balancing routing rules apply to a given IP address and describes how the client connection would be handled. This function is useful when you are evaluating connection load balancing policies you have created, to ensure they work the way you expect them to.

You pass this function an IP address of a client connection, and it uses the load balancing routing rules to determine how the connection will be handled. The logic this function uses is the same logic used when Vertica load balances client connections, including determining which nodes are available to handle the client connection.

This function assumes the client connection has opted into being load balanced. If actual clients have not opted into load balancing, the connections will not be redirected. See [Load balancing in ADO.NET](#), [Load balancing in JDBC](#), and [Load balancing](#), for information on enabling load balancing on the client. For vsql, use the `-C` command-line option to enable load balancing.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESCRIBE_LOAD_BALANCE_DECISION('ip_address')
```

Arguments

**'ip\_address'**

An IP address of a client connection to be tested against the load balancing rules. This can be either an IPv4 or IPv6 address.

Return value

A step-by-step description of how the load balancing rules are being evaluated, including the final decision of which node in the database has been chosen to service the connection.

Privileges

None.

Examples

The following example demonstrates calling `DESCRIBE_LOAD_BALANCE_DECISION` with three different IP addresses, two of which are handled by different routing rules, and one which is not handled by any rule.

```
=> SELECT describe_load_balance_decision('192.168.1.25');
 describe_load_balance_decision

Describing load balance decision for address [192.168.1.25]
Load balance cache internal version id (node-local): [2]
Considered rule [etl_rule] source ip filter [10.20.100.0/24]... input address
does not match source ip filter for this rule.
Considered rule [internal_clients] source ip filter [192.168.1.0/24]... input
address matches this rule
Matched to load balance group [group_1] the group has policy [ROUNDROBIN]

- [GET\\_CLIENT\\_LABEL](#)
- [RESET\\_LOAD\\_BALANCE\\_POLICY](#)
- [SET\\_CLIENT\\_LABEL](#)

- [SET\\_LOAD\\_BALANCE\\_POLICY](#)

## GET\_CLIENT\_LABEL

Returns the client connection label for the current session.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
GET_CLIENT_LABEL()
```

Privileges

None

Examples

Return the current client connection label:

```
=> SELECT GET_CLIENT_LABEL();
 GET_CLIENT_LABEL

data_load_application
(1 row)
```

See also

[Setting a client connection label](#)

[RESET\\_LOAD\\_BALANCE\\_POLICY](#)

Resets the counter each host in the cluster maintains, to track which host it will refer a client to when the native [connection load balancing scheme](#) is set to **ROUNDROBIN** . To reset the counter, run this function on all cluster nodes.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RESET_LOAD_BALANCE_POLICY()
```

Privileges

Superuser

Examples

```
=> SELECT RESET_LOAD_BALANCE_POLICY();

 RESET_LOAD_BALANCE_POLICY

Successfully reset stateful client load balance policies: "roundrobin".
(1 row)
```

## SET\_CLIENT\_LABEL

Assigns a label to a client connection for the current session. You can use this label to distinguish client connections.

Labels appear in the [SESSIONS](#) system table. However, only certain [Data collector](#) tables show new client labels set by SET\_CLIENT\_LABEL. For example, DC\_REQUESTS\_ISSUED reflects changes by SET\_CLIENT\_LABEL, while DC\_SESSION\_STARTS, which collects login data before SET\_CLIENT\_LABEL can be run, does not.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SET_CLIENT_LABEL('label-name')
```

## Parameters

### **label-name**

VARCHAR name assigned to the client connection label.

## Privileges

None

## Examples

Assign label `data_load_application` to the current client connection:

```
=> SELECT SET_CLIENT_LABEL('data_load_application');
 SET_CLIENT_LABEL

client_label set to data_load_application
(1 row)
```

## See also

[Setting a client connection label](#)

`SET_LOAD_BALANCE_POLICY`

Sets how native connection load balancing chooses a host to handle a client connection.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

## Behavior type

[Volatile](#)

## Syntax

```
SET_LOAD_BALANCE_POLICY('policy')
```

## Parameters

### **policy**

The name of the load balancing policy to use, one of the following:

- **NONE** (default): Disables native connection load balancing.
- **ROUNDROBIN** : Chooses the next host from a circular list of hosts in the cluster that are up—for example, in a three-node cluster, iterates over node1, node2, and node3, then wraps back to node1. Each host in the cluster maintains its own pointer to the next host in the circular list, rather than there being a single cluster-wide state.
- **RANDOM** : Randomly chooses a host from among all hosts in the cluster that are up.

### Note

Even if the load balancing policy is set on the server to something other than **NONE** , clients must indicate they want their connections to be load balanced by setting a connection property.

## Privileges

Superuser

## Examples

The following example demonstrates enabling native connection load balancing on the server by setting the load balancing scheme to **ROUNDROBIN** :

```
=> SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
 SET_LOAD_BALANCE_POLICY

Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)
```

## Data-type-specific functions

Vertica provides functions for use with specific data types, described in this section.

## In this section

- [Collection functions](#)
- [Date/time functions](#)
- [IP address functions](#)
- [Sequence functions](#)
- [String functions](#)
- [URI functions](#)
- [UUID functions](#)

## Collection functions

The functions in this section apply to collection types (arrays and sets).

Some functions apply aggregation operations (such as sum) to collections. These function names all begin with APPLY.

Other functions in this section operate specifically on arrays or sets, as indicated on the individual reference pages. Array functions operate on both native array values and array values in external tables.

## Notes

- Arrays are 0-indexed. The first element's ordinal position is 0, second is 1, and so on. Indexes are not meaningful for sets.
- Unless otherwise stated, functions operate on one-dimensional (1D) collections only. To use multidimensional arrays, you must first dereference to a 1D array type. Sets can only be one-dimensional.

## In this section

- [TO\\_JSON](#)
- [UNNEST](#)

## APPLY\_AVG

Returns the average of all elements in a collection (array or set) with numeric values.

### Behavior type

[Immutable](#)

### Syntax

```
APPLY_AVG(collection)
```

### Arguments

#### ***collection***

Target collection

### Null-handling

The following cases return NULL:

- if the input collection is NULL
- if the input collection contains only null values
- if the input collection is empty

If the input collection contains a mix of null and non-null elements, only the non-null values are considered in the calculation of the average.

## Examples

```
=> SELECT apply_avg(ARRAY[1,2.4,5,6]);
apply_avg

3.6
(1 row)
```

See also

- [APPLY\\_SUM](#)

## APPLY\_COUNT (ARRAY\_COUNT)

Returns the total number of non-null elements in a collection (array or set). To count all elements including nulls, use [APPLY\\_COUNT\\_ELEMENTS \(ARRAY\\_LENGTH\)](#).

Behavior type

[Immutable](#)

Syntax

```
APPLY_COUNT(collection)
```

ARRAY\_COUNT is a synonym of APPLY\_COUNT .

Arguments

***collection***

Target collection

Null-handling

Null values are not included in the count.

Examples

The array in this example contains six elements, one of which is null:

```
=> SELECT apply_count(ARRAY[1,NULL,3,7,8,5]);
apply_count

5
(1 row)
```

## APPLY\_COUNT\_ELEMENTS (ARRAY\_LENGTH)

Returns the total number of elements in a collection (array or set), including NULLs. To count only non-null values, use [APPLY\\_COUNT \(ARRAY\\_COUNT\)](#).

Behavior type

[Immutable](#)

Syntax

```
APPLY_COUNT_ELEMENTS(collection)
```

ARRAY\_LENGTH is a synonym of APPLY\_COUNT\_ELEMENTS .

Arguments

***collection***

Target collection

Null-handling

This function counts all members, including nulls.

An empty collection ( [ARRAY\[\]](#) or [SET\[\]](#) ) has a length of 0. A collection containing a single null ( [ARRAY\[null\]](#) or [SET\[null\]](#) ) has a length of 1.

Examples

The following array has six elements including one null:

```
=> SELECT apply_count_elements(ARRAY[1,NULL,3,7,8,5]);
```

```
apply_count_elements
```

```

 6
```

```
(1 row)
```

As the previous example shows, a null element is an element. Thus, an array containing only a null element has one element:

```
=> SELECT apply_count_elements(ARRAY[null]);
```

```
apply_count_elements
```

```

 1
```

```
(1 row)
```

A set does not contain duplicates. If you construct a set and pass it directly to this function, the result could differ from the number of inputs:

```
=> SELECT apply_count_elements(SET[1,1,3]);
```

```
apply_count_elements
```

```

 2
```

```
(1 row)
```

## APPLY\_MAX

Returns the largest non-null element in a collection (array or set). This function is similar to the [MAX \[aggregate\]](#) function; APPLY\_MAX operates on elements of a collection and MAX operates on an expression such as a column selection.

Behavior type

[Immutable](#)

Syntax

```
APPLY_MAX(collection)
```

Arguments

***collection***

Target collection

Null-handling

This function ignores null elements. If all elements are null or the collection is empty, this function returns null.

Examples

```
=> SELECT apply_max(ARRAY[1,3.4,15]);
```

```
apply_max
```

```

 15.0
```

```
(1 row)
```

## APPLY\_MIN

Returns the smallest non-null element in a collection (array or set). This function is similar to the [MIN \[aggregate\]](#) function; APPLY\_MIN operates on elements of a collection and MIN operates on an expression such as a column selection.

Behavior type

[Immutable](#)

Syntax

```
APPLY_MIN(collection)
```

Arguments

***collection***

Target collection

Null-handling

This function ignores null elements. If all elements are null or the collection is empty, this function returns null.

Examples

```
=> SELECT apply_min(ARRAY[1,3.4,15]);
```

```
apply_min
```

```

 1.0
```

```
(1 row)
```

## APPLY\_SUM

Computes the sum of all elements in a collection (array or set) of numeric values (INTEGER, FLOAT, NUMERIC, or INTERVAL).

Behavior type

[Immutable](#)

Syntax

```
APPLY_SUM(collection)
```

Arguments

***collection***

Target collection

Null-handling

The following cases return NULL:

- if the input collection is NULL
- if the input collection contains only null values
- if the input collection is empty

Examples

```
=> SELECT apply_sum(ARRAY[12.5,3,4,1]);
```

```
apply_sum
```

```

 20.5
```

```
(1 row)
```

See also

- [APPLY\\_AVG](#)

## ARRAY\_CAT

Concatenates two arrays of the same element type and dimensionality. For example, ROW elements must have the same fields.

If the inputs are both bounded, the bound for the result is the sum of the bounds of the inputs.

If any input is unbounded, the result is unbounded with a binary size that is the sum of the sizes of the inputs.

Behavior type

[Immutable](#)

Syntax

```
ARRAY_CAT(array1,array2)
```

Arguments

***array1 , array2***

Arrays of matching dimensionality and element type

Null-handling

If either input is NULL, the function returns NULL.

Examples

Types are coerced if necessary, as shown in the second example.

```
=> SELECT array_cat(ARRAY[1,2], ARRAY[3,4,5]);
```

```
array_cat
```

```

[1,2,3,4,5]
```

```
(1 row)
```

```
=> SELECT array_cat(ARRAY[1,2], ARRAY[3,4,5.0]);
```

```
array_cat
```

```

["1.0","2.0","3.0","4.0","5.0"]
```

```
(1 row)
```

## ARRAY\_CONTAINS

Returns true if the specified element is found in the array and false if not. Both arguments must be non-null, but the array may be empty.

### Deprecated

This function has been renamed to [CONTAINS](#).

## ARRAY\_DIMS

Returns the dimensionality of the input array.

Behavior type

[Immutable](#)

Syntax

```
ARRAY_DIMS(array)
```

Arguments

### *array*

Target array

Examples

```
=> SELECT array_dims(ARRAY[[1,2],[2,3]]);
```

```
array_dims
```

```

2
```

```
(1 row)
```

## ARRAY\_FIND

Returns the ordinal position of a specified element in an array, or -1 if not found. This function uses null-safe equality checks when testing elements.

Behavior type

[Immutable](#)

Syntax

```
ARRAY_FIND(array, { value | lambda-expression })
```

Arguments

### *array*

Target array.

### *value*

Value to search for; type must match or be coercible to the element type of the array.

### *lambda-expression*

[Lambda function](#) to apply to each element. The function must return a Boolean value. The first argument to the function is the element, and the optional second element is the index of the element.

Examples

The function returns the first occurrence of the specified element. However, nothing ensures that value is unique in the array:

```
=> SELECT array_find(ARRAY[1,2,7,5,7],7);
array_find

 2
(1 row)
```

The function returns -1 if the specified element is not found:

```
=> SELECT array_find(ARRAY[1,3,5,7],4);
array_find

 -1
(1 row)
```

You can search for complex element types:

```
=> SELECT ARRAY_FIND(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
 ARRAY[1,2,3]);
ARRAY_FIND

 0
(1 row)

=> SELECT ARRAY_FIND(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
 ARRAY[1,null,4]);
ARRAY_FIND

 1
(1 row)
```

The second example, comparing arrays with null elements, finds a match because ARRAY\_FIND uses a null-safe equality check when evaluating elements.

#### Lambdas

Consider a table of departments where each department has an array of ROW elements representing employees. The following example searches for a specific employee name in those records. The results show that Alice works (or has worked) for two departments:

```
=> SELECT deptID, ARRAY_FIND(employees, e -> e.name = 'Alice Adams') AS 'has_alice'
FROM departments;
deptID | has_alice
-----+-----
 1 | 0
 2 | -1
 3 | 0
(3 rows)
```

In the following example, each person in the table has an array of email addresses, and the function locates fake addresses. The function takes one argument, the array element to test, and calls a regular-expression function that returns a Boolean:

```
=> SELECT name, ARRAY_FIND(email, e -> REGEXP_LIKE(e,'example.com','i'))
 AS 'example.com'
FROM people;
name | example.com
-----+-----
Elaine Jackson | -1
Frank Adams | 0
Lee Jones | -1
M Smith | 0
(4 rows)
```

See also

- [CONTAINS](#)

- [FILTER](#)

## CONTAINS

Returns true if the specified element is found in the collection and false if not. This function uses null-safe equality checks when testing elements.

Behavior type

[Immutable](#)

Syntax

```
CONTAINS(collection, { value | lambda-expression })
```

Arguments

### *collection*

Target collection ( [ARRAY](#) or [SET](#) ).

### *value*

Value to search for; type must match or be coercible to the element type of the collection.

### *lambda-expression*

[Lambda function](#) to apply to each element. The function must return a Boolean value. The first argument to the function is the element, and the optional second element is the index of the element.

Examples

```
=> SELECT CONTAINS(SET[1,2,3,4],2);
contains

t
(1 row)
```

You can search for NULL as an element value:

```
=> SELECT CONTAINS(ARRAY[1,null,2],null);
contains

t
(1 row)
```

You can search for complex element types:

```
=> SELECT CONTAINS(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
 ARRAY[1,2,3]);
CONTAINS

t
(1 row)

=> SELECT CONTAINS(ARRAY[ARRAY[1,2,3],ARRAY[1,null,4]],
 ARRAY[1,null,4]);
CONTAINS

t
(1 row)
```

The second example, comparing arrays with null elements, returns true because CONTAINS uses a null-safe equality check when evaluating elements.

In the following example, the orders table has the following definition:

```
=> CREATE EXTERNAL TABLE orders(
 orderid int,
 accountid int,
 shipments Array[
 ROW(
 shipid int,
 address ROW(
 street varchar,
 city varchar,
 zip int
),
 shipdate date
)
]
) AS COPY FROM '...' PARQUET;
```

The following query tests for a specific order. When passing a ROW literal as the second argument, cast any ambiguous fields to ensure type matches:

```
=> SELECT CONTAINS(shipments,
 ROW(1,ROW('911 San Marcos St'::VARCHAR,
 'Austin'::VARCHAR, 73344),
 '2020-11-05'::DATE))
FROM orders;
CONTAINS

t
f
f
(3 rows)
```

#### Lambdas

Consider a table of departments where each department has an array of ROW elements representing employees. The following query finds departments with early hires (low employee IDs):

```
=> SELECT deptID FROM departments
WHERE CONTAINS(employees, e -> e.id < 20);
deptID

1
3
(2 rows)
```

In the following example, a schedules table includes an array of events, where each event is a ROW with several fields:

```
=> CREATE TABLE schedules
 (guest VARCHAR,
 events ARRAY[ROW(e_date DATE, e_name VARCHAR, price NUMERIC(8,2))]);
```

You can use the [CONTAINS](#) function with a lambda expression to find people who have more than one event on the same day. The second argument, `idx`, is the index of the current element:

```
=> SELECT guest FROM schedules
WHERE CONTAINS(events, (e, idx) ->
 (idx < ARRAY_LENGTH(events) - 1
 AND (e.e_date = events[idx + 1].e_date));
guest

Alice Adams
(1 row)
```

See also

- [ARRAY\\_FIND](#)
- [FILTER](#)

## EXPLODE

Expands the elements of one or more collection columns ([ARRAY](#) or [SET](#)) into individual table rows, one row per element. For each exploded collection, the results include two columns, one for the element index, and one for the value at that position. If the function explodes a single collection, these columns are named `position` and `value` by default. If the function explodes two or more collections, the columns for each collection are named `pos_ column-name` and `val_ column-name`. You can use an AS clause in the SELECT to change these column names.

EXPLODE and [UNNEST](#) both expand collections. They have the following differences:

- By default, EXPLODE expands only the first collection it is passed and UNNEST expands all of them. See the [explode\\_count](#) and [explode\\_all](#) parameters.
- By default, EXPLODE returns element positions in an `index` column and UNNEST does not. See the [with\\_offsets](#) parameter.
- By default, EXPLODE requires an OVER clause and UNNEST ignores an OVER clause if present. See the [skip\\_partitioning](#) parameter.

Behavior type

[Immutable](#)

Syntax

```
EXPLODE (column[,...] [USING PARAMETERS param=value])
[OVER ([window-partition-clause])]
```

Arguments

### **column**

Column in the table being queried. Unless [explode\\_all](#) is true, you must specify at least as many collection columns as the value of the [explode\\_count](#) parameter. Columns that are not collections are passed through without modification.

Passthrough columns are not needed if [skip\\_partitioning](#) is true.

### **OVER(...)**

How to partition and sort input data. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses. For EXPLODE, use OVER() or OVER(PARTITION BEST).

This clause is ignored if [skip\\_partitioning](#) is true.

Parameters

### **explode\_all (BOOLEAN)**

If true, explode all collection columns. When [explode\\_all](#) is true, passthrough columns are not permitted.

**Default:** false

### **explode\_count (INT)**

The number of collection columns to explode. The function checks each column, up to this value, and either explodes it if it is a collection or passes it through if it is not a collection or if this limit has been reached. If the value of [explode\\_count](#) is greater than the number of collection columns specified, the function returns an error.

If [explode\\_all](#) is true, you cannot specify [explode\\_count](#).

**Default:** 1

### **skip\_partitioning (BOOLEAN)**

Whether to skip partitioning and ignore the OVER clause if present. EXPLODE translates a single row of input into multiple rows of output, one per collection element. There is, therefore, usually no benefit to partitioning the input first. Skipping partitioning can help a query avoid an expensive sort or merge operation. Even so, setting this parameter can negatively affect performance in rare cases.

**Default:** false

### **with\_offset (BOOLEAN)**

Whether to return the index of each element.

**Default:** true

Null-handling

This function expands each element in a collection into a row, including null elements. If the input column is NULL or an empty collection, the function produces no rows for that column:

```
=> SELECT EXPLODE(ARRAY[1,2,null,4]) OVER();
```

```
position | value
```

```
-----+-----
0 | 1
1 | 2
2 |
3 | 4
```

```
(4 rows)
```

```
=> SELECT EXPLODE(ARRAY[]::ARRAY[INT]) OVER();
```

```
position | value
```

```
-----+-----
(0 rows)
```

```
=> SELECT EXPLODE(NULL::ARRAY[INT]) OVER();
```

```
position | value
```

```
-----+-----
(0 rows)
```

Joining on results

To use JOIN with this function you must set the `skip_partitioning` parameter, either in the function call or as a session parameter.

You can use the output of this function as if it were a relation by using CROSS JOIN or LEFT JOIN LATERAL in a query. Other JOIN types are not supported.

Consider the following table of students and exam scores:

```
=> SELECT * FROM tests;
```

```
student | scores | questions
```

```
-----+-----+-----
Bob | [92,78,79] | [20,20,100]
Lee | |
Pat | [] | []
Sam | [97,98,85] | [20,20,100]
Tom | [68,75,82,91] | [20,20,100,100]
```

```
(5 rows)
```

The following query finds the best test scores across all students who have scores:

```
=> ALTER SESSION SET UDPARAMETER FOR ComplexTypesLib skip_partitioning = true;
```

```
=> SELECT student, score FROM tests
CROSS JOIN EXPLODE(scores) AS t (pos, score)
ORDER BY score DESC;
```

```
student | score
```

```
-----+-----
Sam | 98
Sam | 97
Bob | 92
Tom | 91
Sam | 85
Tom | 82
Bob | 79
Bob | 78
Tom | 75
Tom | 68
```

```
(10 rows)
```

The following query returns maximum and average per-question scores, considering both the exam score and the number of questions:

```
=> SELECT student, MAX(score/qcount), AVG(score/qcount) FROM tests
 CROSS JOIN EXPLODE(scores, questions USING PARAMETERS explode_count=2)
 AS t(pos_s, score, pos_q, qcount)
 GROUP BY student;
student | MAX | AVG
-----+-----+-----
Bob | 4.6000000000000000 | 3.04333333333333
Sam | 4.9000000000000000 | 3.42222222222222
Tom | 4.5500000000000000 | 2.37
(3 rows)
```

These queries produce results for three of the five students. One student has a null value for scores and another has an empty array. These rows are not included in the function's output.

To include null and empty arrays in output, use LEFT JOIN LATERAL instead of CROSS JOIN:

```
=> SELECT student, MIN(score), AVG(score) FROM tests
 LEFT JOIN LATERAL EXPLODE(scores) AS t (pos, score)
 GROUP BY student;
student | MIN | AVG
-----+-----+-----
Bob | 78 | 83
Lee | |
Pat | |
Sam | 85 | 93.33333333333333
Tom | 68 | 79
(5 rows)
```

The LATERAL keyword is required with LEFT JOIN. It is optional for CROSS JOIN.

#### Examples

Consider an orders table with the following contents:

```
=> SELECT orderkey, custkey, prodkey, orderprices, email_addr
 FROM orders LIMIT 5;
orderkey | custkey | prodkey | orderprices | email_addr
-----+-----+-----+-----+-----
113-341987 | 342799 | ["MG-7190 ", "VA-4028 ", "EH-1247 ", "MS-7018 "] | ["60.00", "67.00", "22.00", "14.99"] | ["bob@example.com", "robert.jones@example.com"]
111-952000 | 342845 | ["ID-2586 ", "IC-9010 ", "MH-2401 ", "JC-1905 "] | ["22.00", "35.00", null, "12.00"] | ["br92@cs.example.edu"]
111-345634 | 342536 | ["RS-0731 ", "SJ-2021 "] | ["50.00", null] | [null]
113-965086 | 342176 | ["GW-1808 "] | ["108.00"] | ["joe.smith@example.com"]
111-335121 | 342321 | ["TF-3556 "] | ["50.00"] | ["789123@example-isp.com", "alexjohnson@example.com", "monica@eng.example.com", "sara@johnson.example.name", null]
(5 rows)
```

The following query explodes the order prices for a single customer. The other two columns are passed through and are repeated for each returned row:

```
=> SELECT EXPLODE(orderprices, custkey, email_addr
 USING PARAMETERS skip_partitioning=true)
 AS (position, orderprices, custkey, email_addr)
 FROM orders WHERE custkey='342845' ORDER BY orderprices;
position | orderprices | custkey | email_addr
-----+-----+-----+-----
2 | | 342845 | ["br92@cs.example.edu", null]
3 | 12.00 | 342845 | ["br92@cs.example.edu", null]
0 | 22.00 | 342845 | ["br92@cs.example.edu", null]
1 | 35.00 | 342845 | ["br92@cs.example.edu", null]
(4 rows)
```

The previous example uses the `skip_partitioning` parameter. Instead of setting it for each call to `EXPLODE`, you can set it as a session parameter. `EXPLODE` is part of the `ComplexTypesLib` UDX library. The following example returns the same results:

```
=> ALTER SESSION SET UDPARAMETER FOR ComplexTypesLib skip_partitioning=true;

=> SELECT EXPLODE(orderprices, custkey, email_addrs)
 AS (position, orderprices, custkey, email_addrs)
 FROM orders WHERE custkey='342845' ORDER BY orderprices;
```

You can explode more than one column by specifying the `explode_count` parameter:

```
=> SELECT EXPLODE(orderkey, prodkey, orderprices
 USING PARAMETERS explode_count=2, skip_partitioning=true)
 AS (orderkey,pk_idx,pk_val,ord_idx,ord_val)
 FROM orders
 WHERE orderkey='113-341987';

orderkey | pk_idx | pk_val | ord_idx | ord_val
-----+-----+-----+-----+-----
113-341987 | 0 | MG-7190 | 0 | 60.00
113-341987 | 0 | MG-7190 | 1 | 67.00
113-341987 | 0 | MG-7190 | 2 | 22.00
113-341987 | 0 | MG-7190 | 3 | 14.99
113-341987 | 1 | VA-4028 | 0 | 60.00
113-341987 | 1 | VA-4028 | 1 | 67.00
113-341987 | 1 | VA-4028 | 2 | 22.00
113-341987 | 1 | VA-4028 | 3 | 14.99
113-341987 | 2 | EH-1247 | 0 | 60.00
113-341987 | 2 | EH-1247 | 1 | 67.00
113-341987 | 2 | EH-1247 | 2 | 22.00
113-341987 | 2 | EH-1247 | 3 | 14.99
113-341987 | 3 | MS-7018 | 0 | 60.00
113-341987 | 3 | MS-7018 | 1 | 67.00
113-341987 | 3 | MS-7018 | 2 | 22.00
113-341987 | 3 | MS-7018 | 3 | 14.99
(16 rows)
```

The following example uses a multi-dimensional array:

```
=> SELECT name, pingtimes FROM network_tests;

name | pingtimes
-----+-----
eng1 | [[24.24,25.27,27.16,24.97],[23.97,25.01,28.12,29.5]]
eng2 | [[27.12,27.91,28.11,26.95],[29.01,28.99,30.11,31.56]]
qa1 | [[23.15,25.11,24.63,23.91],[22.85,22.86,23.91,31.52]]
(3 rows)

=> SELECT EXPLODE(name, pingtimes USING PARAMETERS explode_count=1) OVER()
 FROM network_tests;

name | position | value
-----+-----+-----
eng1 | 0 | [24.24,25.27,27.16,24.97]
eng1 | 1 | [23.97,25.01,28.12,29.5]
eng2 | 0 | [27.12,27.91,28.11,26.95]
eng2 | 1 | [29.01,28.99,30.11,31.56]
qa1 | 0 | [23.15,25.11,24.63,23.91]
qa1 | 1 | [22.85,22.86,23.91,31.52]
(6 rows)
```

You can rewrite the previous query as follows to produce the same results:

```
=> SELECT name, EXPLODE(pingtimes USING PARAMETERS skip_partitioning=true)
 FROM network_tests;
```

## FILTER

Takes an input array and returns an array containing only elements that meet a specified condition. This function uses null-safe equality checks when testing elements.

Behavior type

[Immutable](#)

Syntax

```
FILTER(array, lambda-expression)
```

Arguments

**array**

Input array.

**lambda-expression**

[Lambda function](#) to apply to each element. The function must return a Boolean value. The first argument to the function is the element, and the optional second element is the index of the element.

Examples

Given a table that contains names and arrays of email addresses, the following query filters out fake email addresses and returns the rest:

```
=> SELECT name, FILTER(email, e -> NOT REGEXP_LIKE(e,'example.com','i')) AS 'real_email'
FROM people;
 name | real_email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Frank Adams | []
Lee Jones | ["lee.jones@somewhere.org"]
M Smith | ["ms@msmith.com"]
(4 rows)
```

You can use the results in a WHERE clause to exclude rows that no longer contain any email addresses:

```
=> SELECT name, FILTER(email, e -> NOT REGEXP_LIKE(e,'example.com','i')) AS 'real_email'
FROM people
WHERE ARRAY_LENGTH(real_email) > 0;
 name | real_email
-----+-----
Elaine Jackson | ["ejackson@somewhere.org","elaine@jackson.com"]
Lee Jones | ["lee.jones@somewhere.org"]
M Smith | ["ms@msmith.com"]
(3 rows)
```

See also

- [CONTAINS](#)
- [ARRAY\\_FIND](#)

## IMPLODE

Takes a column of any scalar type and returns an unbounded array. Combined with GROUP BY, this function can be used to reverse an [EXPLODE](#) operation.

Behavior type

- [Immutable](#) if the WITHIN GROUP ORDER BY clause specifies a column or set of columns that resolves to unique element values within each output array group.
- [Volatile](#) otherwise because results are non-commutative.

Syntax

```
IMPLODE (input-column [USING PARAMETERS param=value[,...]]
[within-group-order-by-clause])
```

Arguments

**input-column**

Column of any scalar type from which to create the array.

[\[within-group-order-by-clause\]/\(sql-reference/functions/aggregate-functions/within-group-order-by-clause.html\)](#)

Sorts elements within each output array group:

```
WITHIN GROUP (ORDER BY { column-expression[sort-qualifiers] }{...})
```

*sort-qualifiers* : { ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] }

#### Tip

WITHIN GROUP ORDER BY can consume a large amount of memory per group. To minimize memory consumption, create projections that support [GROUPBY PIPELINED](#).

Parameters

#### **allow\_truncate**

Boolean, if true truncates results when output length exceeds column size. If false (the default), the function returns an error if the output array is too large.

Even if this parameter is set to true, IMplode returns an error if any single array element is too large. Truncation removes elements from the output array but does not alter individual elements.

#### **max\_binary\_size**

The maximum binary size in bytes for the returned array. If you omit this parameter, IMplode uses the value of the configuration parameter [DefaultArrayBinarySize](#).

Examples

Consider a table with the following contents:

```
=> SELECT * FROM filtered;
```

position	itemprice	itemkey
0	14.99	345
0	27.99	567
1	18.99	567
1	35.99	345
2	14.99	123

(5 rows)

The following query calls IMplode to assemble prices into arrays (grouped by keys):

```
=> SELECT itemkey AS key, IMplode(itemprice) AS prices
FROM filtered GROUP BY itemkey ORDER BY itemkey;
```

key	prices
123	["14.99"]
345	["35.99","14.99"]
567	["27.99","18.99"]

(3 rows)

You can modify this query by including a WITHIN GROUP ORDER BY clause, which specifies how to sort array elements within each group:

```
=> SELECT itemkey AS key, IMplode(itemprice) WITHIN GROUP (ORDER BY itemprice) AS prices
FROM filtered GROUP BY itemkey ORDER BY itemkey;
```

key	prices
123	["14.99"]
345	["14.99","35.99"]
567	["18.99","27.99"]

(3 rows)

See [Arrays and sets \(collections\)](#) for a fuller example.

## SET\_UNION

Returns a [SET](#) containing all elements of two input sets.

If the inputs are both bounded, the bound for the result is the sum of the bounds of the inputs.

If any input is unbounded, the result is unbounded with a binary size that is the sum of the sizes of the inputs.

Behavior type

[Immutable](#)

Syntax

```
SET_UNION(set1,set2)
```

Arguments

***set1*** , ***set2***

Sets of matching element type

Null-handling

- Null arguments are ignored. If one of the inputs is null, the function returns the non-null input. In other words, an argument of NULL is equivalent to SET[*i*].
- If both inputs are null, the function returns null.

Examples

```
=> SELECT SET_UNION(SET[1,2,4], SET[2,3,4,5.9]);
set_union

["1.0","2.0","3.0","4.0","5.9"]
(1 row)
```

## STRING\_TO\_ARRAY

Splits a string containing array values and returns a native one-dimensional array. The output does not include the "ARRAY" keyword. This function does not support nested (multi-dimensional) arrays.

This function returns array elements as strings by default. You can cast to other types, as in the following example:

```
=> SELECT STRING_TO_ARRAY('[1,2,3]')::ARRAY[INT];
```

Behavior

[Immutable](#)

Syntax

```
STRING_TO_ARRAY(string [USING PARAMETERS param=value[,...]])
```

The following syntax is deprecated:

```
STRING_TO_ARRAY(string, delimiter)
```

Arguments

***string***

String representation of a one-dimensional array; can be a VARCHAR or LONG VARCHAR column, a literal string, or the string output of an expression.

Spaces in the string are removed unless elements are individually quoted. For example, 'a,b,c' is equivalent to 'a,b,c' . To preserve the space, use "' a','b','c' " .

Parameters

These parameters behave the same way as the corresponding options when loading delimited data (see [DELIMITED](#)).

No parameter may have the same value as any other parameter.

**collection\_delimiter**

The character or character sequence used to separate array elements (VARCHAR(8)). You can use any ASCII values in the range E'000' to E'177', inclusive.

**Default:** Comma (',').

### collection\_open , collection\_close

The characters that mark the beginning and end of the array (VARCHAR(8)). It is an error to use these characters elsewhere within the list of elements without escaping them. These characters can be omitted from the input string.

**Default:** Square brackets ('[' and ']').

### collection\_null\_element

The string representing a null element value (VARCHAR(65000)). You can specify a null value using any ASCII values in the range E'\001' to E'\177' inclusive (any ASCII value except NULL: E'\000').

**Default:** 'null'

### collection\_enclose

An optional quote character within which to enclose individual elements, allowing delimiter characters to be embedded in string values. You can choose any ASCII value in the range E'\001' to E'\177' inclusive (any ASCII character except NULL: E'\000'). Elements do not need to be enclosed by this value.

**Default:** double quote ('"')

### Examples

The function uses comma as the default delimiter. You can specify a different value:

```
=> SELECT STRING_TO_ARRAY('[1,3,5]');
STRING_TO_ARRAY

["1","3","5"]
(1 row)

=> SELECT STRING_TO_ARRAY('[t|t|f|t]' USING PARAMETERS collection_delimiter = '|');
STRING_TO_ARRAY

["t","t","f","t"]
(1 row)
```

The bounding brackets are optional:

```
=> SELECT STRING_TO_ARRAY('t|t|f|t' USING PARAMETERS collection_delimiter = '|');
STRING_TO_ARRAY

["t","t","f","t"]
(1 row)
```

The input can use other characters for open and close:

```
=> SELECT STRING_TO_ARRAY('{NASA-1683,NASA-7867,SPX-76}' USING PARAMETERS collection_open = '{', collection_close = '}');
STRING_TO_ARRAY

["NASA-1683","NASA-7867","SPX-76"]
(1 row)
```

By default the string 'null' in input is treated as a null value:

```
=> SELECT STRING_TO_ARRAY('{us-1672,null,darpa-1963}' USING PARAMETERS collection_open = '{', collection_close = '}');
STRING_TO_ARRAY

["us-1672",null,"darpa-1963"]
(1 row)
```

In the following example, the input comes from a column:

```
=> SELECT STRING_TO_ARRAY(name USING PARAMETERS collection_delimiter=' ') FROM employees;
STRING_TO_ARRAY

["Howard","Wolowitz"]
["Sheldon","Cooper"]
(2 rows)
```

## TO\_JSON

Returns the JSON representation of a complex-type argument, including mixed and nested complex types. This is the same format that queries of complex-type columns return.

### Behavior

[Immutable](#)

### Syntax

```
TO_JSON(value)
```

### Arguments

#### *value*

Column or literal of a complex type

### Examples

These examples query the following table:

```
=> SELECT name, contact FROM customers;
 name | contact
-----+-----
Missy Cooper | {"street":"911 San Marcos St","city":"Austin","zipcode":73344,"email":["missy@mit.edu","mcooper@cern.gov"]}
Sheldon Cooper | {"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001,"email":["shelly@meemaw.name","cooper@caltech.edu"]}
Leonard Hofstadter | {"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001,"email":["hofstadter@caltech.edu"]}
Leslie Winkle | {"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001,"email":[]}
Raj Koothrappali | {"street":null,"city":"Pasadena","zipcode":91001,"email":["raj@available.com"]}
Stuart Bloom |
(6 rows)
```

You can call TO\_JSON on a column or on specific fields or array elements:

```
=> SELECT TO_JSON(contact) FROM customers;
 to_json

{"street":"911 San Marcos St","city":"Austin","zipcode":73344,"email":["missy@mit.edu","mcooper@cern.gov"]}
{"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001,"email":["shelly@meemaw.name","cooper@caltech.edu"]}
{"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001,"email":["hofstadter@caltech.edu"]}
{"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001,"email":[]}
{"street":null,"city":"Pasadena","zipcode":91001,"email":["raj@available.com"]}
(6 rows)

=> SELECT TO_JSON(contact.email) FROM customers;
 to_json

["missy@mit.edu","mcooper@cern.gov"]
["shelly@meemaw.name","cooper@caltech.edu"]
["hofstadter@caltech.edu"]
[]
["raj@available.com"]
(6 rows)
```

When calling TO\_JSON with a SET, note that duplicates are removed and elements can be reordered:

```
=> SELECT TO_JSON(SET[1683,7867,76,76]);
 TO_JSON

[76,1683,7867]
(1 row)
```

## UNNEST

Expands the elements of one or more collection columns ([ARRAY](#) or [SET](#)) into individual rows. If called with a single array, UNNEST returns the

elements in a column named `value` . If called with two or more arrays, it returns columns named `val_ column-name` . You can use an AS clause in the SELECT to change these names.

UNNEST and [EXPLODE](#) both expand collections. They have the following differences:

- By default, UNNEST expands all passed collections and EXPLODE expands only the first. See the `explode_count` and `explode_all` parameters.
- By default, UNNEST returns only the elements and EXPLODE also returns their positions in an `index` column. See the `with_offsets` parameter.
- By default, UNNEST does not partition its input and ignores an OVER() clause if present. See the `skip_partitioning` parameter.

Behavior type

[Immutable](#)

Syntax

```
UNNEST (column[,...])
[USING PARAMETERS param=value]
[OVER ([window-partition-clause
```

Arguments

### **column**

Column in the table being queried. If `explode_all` is false, you must specify at least as many collection columns as the value of the `explode_count` parameter. Columns that are not collections are passed through without modification.

Passthrough columns are not needed if `skip_partitioning` is true.

### **OVER(...)**

How to partition and sort input data. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses.

This clause only applies if `skip_partitioning` is false.

Parameters

### **explode\_all (BOOLEAN)**

If true, explode all collection columns. When `explode_all` is true, passthrough columns are not permitted.

**Default:** true

### **explode\_count (INT)**

The number of collection columns to explode. The function checks each column, up to this value, and either explodes it if it is a collection or passes it through if it is not a collection or if this limit has been reached. If the value of `explode_count` is greater than the number of collection columns specified, the function returns an error.

If `explode_all` is true, you cannot specify `explode_count` .

**Default:** 1

### **skip\_partitioning (BOOLEAN)**

Whether to skip partitioning and ignore the OVER clause if present. UNNEST translates a single row of input into multiple rows of output, one per collection element. There is, therefore, usually no benefit to partitioning the input first. Skipping partitioning can help a query avoid an expensive sort or merge operation.

**Default:** true

### **with\_offset (BOOLEAN)**

Whether to return the index of each element as an additional column.

**Default:** false

Null-handling

This function expands each element in a collection into a row, including null elements. If the input column is NULL or an empty collection, the function produces no rows for that column:

```
=> SELECT UNNEST(ARRAY[1,2,null,4]) OVER();
```

```
value
```

```

 1
 2

 4
```

```
(4 rows)
```

```
=> SELECT UNNEST(ARRAY[]::ARRAY[INT]) OVER();
```

```
value
```

```

(0 rows)
```

```
=> SELECT UNNEST(NULL::ARRAY[INT]) OVER();
```

```
value
```

```

(0 rows)
```

Joining on results

You can use the output of this function as if it were a relation by using CROSS JOIN or LEFT JOIN LATERAL in a query. Other JOIN types are not supported.

Consider the following table of students and exam scores:

```
=> SELECT * FROM tests;
```

```
student | scores | questions
```

```
-----+-----
Bob | [92,78,79] | [20,20,100]
Lee | |
Pat | [] | []
Sam | [97,98,85] | [20,20,100]
Tom | [68,75,82,91] | [20,20,100,100]
```

```
(5 rows)
```

The following query finds the best test scores across all students who have scores:

```
=> SELECT student, score FROM tests
```

```
CROSS JOIN UNNEST(scores) AS t (score)
```

```
ORDER BY score DESC;
```

```
student | score
```

```
-----+-----
Sam | 98
Sam | 97
Bob | 92
Tom | 91
Sam | 85
Tom | 82
Bob | 79
Bob | 78
Tom | 75
Tom | 68
```

```
(10 rows)
```

The following query returns maximum and average per-question scores, considering both the exam score and the number of questions:

```
=> SELECT student, MAX(score/qcount), AVG(score/qcount) FROM tests
CROSS JOIN UNNEST(scores, questions) AS t(score, qcount)
GROUP BY student;
student | MAX | AVG
-----+-----+-----
Bob | 4.6000000000000000 | 3.04333333333333
Sam | 4.9000000000000000 | 3.42222222222222
Tom | 4.5500000000000000 | 2.37
(3 rows)
```

These queries produce results for three of the five students. One student has a null value for scores and another has an empty array. These rows are not included in the function's output.

To include null and empty arrays in output, use LEFT JOIN LATERAL instead of CROSS JOIN:

```
=> SELECT student, MIN(score), AVG(score) FROM tests
LEFT JOIN LATERAL UNNEST(scores) AS t (score)
GROUP BY student;
student | MIN | AVG
-----+-----+-----
Bob | 78 | 83
Lee | |
Pat | |
Sam | 85 | 93.33333333333333
Tom | 68 | 79
(5 rows)
```

The LATERAL keyword is required with LEFT JOIN. It is optional for CROSS JOIN.

#### Examples

Consider a table with the following definition:

```
=> CREATE TABLE orders (
 orderkey VARCHAR, custkey INT,
 prodkey ARRAY[VARCHAR], orderprices ARRAY[DECIMAL(12,2)],
 email_addrs ARRAY[VARCHAR]);
```

The following query expands one of the array columns. One of the elements is null:

```
=> SELECT UNNEST(orderprices) AS price, custkey, email_addrs
FROM orders WHERE custkey='342845' ORDER BY price;
price | custkey | email_addrs
-----+-----+-----
 | 342845 | ["br92@cs.example.edu"]
12.00 | 342845 | ["br92@cs.example.edu"]
22.00 | 342845 | ["br92@cs.example.edu"]
35.00 | 342845 | ["br92@cs.example.edu"]
(4 rows)
```

UNNEST can expand more than one column:

```
=> SELECT orderkey, UNNEST(prodkey, orderprices)
 FROM orders WHERE orderkey='113-341987';
orderkey | val_prodkey | val_orderprices
-----+-----+-----
113-341987 | MG-7190 | 60.00
113-341987 | MG-7190 | 67.00
113-341987 | MG-7190 | 22.00
113-341987 | MG-7190 | 14.99
113-341987 | VA-4028 | 60.00
113-341987 | VA-4028 | 67.00
113-341987 | VA-4028 | 22.00
113-341987 | VA-4028 | 14.99
113-341987 | EH-1247 | 60.00
113-341987 | EH-1247 | 67.00
113-341987 | EH-1247 | 22.00
113-341987 | EH-1247 | 14.99
113-341987 | MS-7018 | 60.00
113-341987 | MS-7018 | 67.00
113-341987 | MS-7018 | 22.00
113-341987 | MS-7018 | 14.99
(16 rows)
```

## Date/time functions

Date and time functions perform conversion, extraction, or manipulation operations on date and time data types and can return date and time information.

### Usage

Functions that take **TIME** or **TIMESTAMP** inputs come in two variants:

- **TIME WITH TIME ZONE** or **TIMESTAMP WITH TIME ZONE**
- **TIME WITHOUT TIME ZONE** or **TIMESTAMP WITHOUT TIME ZONE**

For brevity, these variants are not shown separately.

The + and \* operators come in commutative pairs; for example, both **DATE + INTEGER** and **INTEGER + DATE** . We show only one of each such pair.

### Daylight savings time considerations

When adding an **INTERVAL** value to (or subtracting an **INTERVAL** value from) a **TIMESTAMP WITH TIME ZONE** value, the days component advances (or decrements) the date of the **TIMESTAMP WITH TIME ZONE** by the indicated number of days. Across daylight saving time changes (with the session time zone set to a time zone that recognizes DST), this means **INTERVAL '1 day'** does not necessarily equal **INTERVAL '24 hours'** .

For example, with the session time zone set to **CST7CDT** :

```
TIMESTAMP WITH TIME ZONE '2014-04-02 12:00-07' + INTERVAL '1 day'
```

produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 12:00-06'
```

Adding **INTERVAL '24 hours'** to the same initial **TIMESTAMP WITH TIME ZONE** produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 13:00-06'
```

This result occurs because there is a change in daylight saving time at **2014-04-03 02:00** in time zone **CST7CDT** .

### Date/time functions in transactions

Certain date/time functions such as **CURRENT\_TIMESTAMP** and **NOW** return the start time of the current transaction; for the duration of that transaction, they return the same value. Other date/time functions such as **TIMEOFDAY** always return the current time.

#### ADD\_MONTHS

Adds the specified number of months to a date and returns the sum as a **DATE** . In general, ADD\_MONTHS returns a date with the same day component as the start date. For example:

```
=> SELECT ADD_MONTHS ('2015-09-15'::date, -2) "2 Months Ago";
```

```
2 Months Ago
```

```

```

```
2015-07-15
```

```
(1 row)
```

Two exceptions apply:

- If the start date's day component is greater than the last day of the result month, ADD\_MONTHS returns the last day of the result month. For example:

```
=> SELECT ADD_MONTHS ('31-Jan-2016'::TIMESTAMP, 1) "Leap Month";
```

```
Leap Month
```

```

```

```
2016-02-29
```

```
(1 row)
```

- If the start date's day component is the last day of that month, and the result month has more days than the start date month, ADD\_MONTHS returns the last day of the result month. For example:

```
=> SELECT ADD_MONTHS ('2015-09-30'::date,-1) "1 Month Ago";
```

```
1 Month Ago
```

```

```

```
2015-08-31
```

```
(1 row)
```

Behavior type

- [Immutable](#) if the *start-date* argument is a **TIMESTAMP** or **DATE**
- [Stable](#) if the *start-date* argument is a **TIMESTAMPTZ**

Syntax

```
ADD_MONTHS (start-date, num-months);
```

Parameters

#### **start-date**

The date to process, an expression that evaluates to one of the following data types:

- **DATE**
- **TIMESTAMP**
- **TIMESTAMPTZ**

#### **num-months**

An integer expression that specifies the number of months to add to or subtract from *start-date* .

Examples

Add one month to the current date:

```
=> SELECT CURRENT_DATE Today;
```

```
Today
```

```

```

```
2016-05-05
```

```
(1 row)
```

```
VMart=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP,1);
```

```
ADD_MONTHS
```

```

```

```
2016-06-05
```

```
(1 row)
```

Subtract four months from the current date:

```
=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP, -4);
```

```
ADD_MONTHS
```

```

```

```
2016-01-05
```

```
(1 row)
```

Add one month to January 31 2016:

```
=> SELECT ADD_MONTHS('31-Jan-2016'::TIMESTAMP, 1) "Leap Month";
Leap Month

2016-02-29
(1 row)
```

The following example sets the timezone to EST; it then adds 24 months to a TIMESTAMPTZ that specifies a PST time zone, so `ADD_MONTHS` takes into account the time change:

```
=> SET TIME ZONE 'America/New_York';
SET
VMart=> SELECT ADD_MONTHS('2008-02-29 23:30 PST'::TIMESTAMPTZ, 24);
ADD_MONTHS

2010-03-01
(1 row)
```

## AGE\_IN\_MONTHS

Returns the difference in months between two dates, expressed as an integer.

Behavior type

- [Immutable](#) if both date arguments are of data type `TIMESTAMP`
- [Stable](#) if either date is a `TIMESTAMPTZ` or only one argument is supplied

Syntax

```
AGE_IN_MONTHS ([date1,] date2)
```

Parameters

**date1**

**date2**

Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets **date2** to the current date. Both parameters must evaluate to one of the following data types:

- `DATE`
- `TIMESTAMP`
- `TIMESTAMPTZ`

If **date1** < **date2**, `AGE_IN_MONTHS` returns a negative value.

Examples

Get the age in months of someone born March 2 1972, as of June 21 1990:

```
=> SELECT AGE_IN_MONTHS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
AGE_IN_MONTHS

219
(1 row)
```

If the first date is less than the second date, `AGE_IN_MONTHS` returns a negative value

```
=> SELECT AGE_IN_MONTHS('1972-03-02'::TIMESTAMP, '1990-06-21'::TIMESTAMP);
AGE_IN_MONTHS

-220
(1 row)
```

Get the age in months of someone who was born November 21 1939, as of today:

```
=> SELECT AGE_IN_MONTHS ('1939-11-21'::DATE);
AGE_IN_MONTHS
```

```

 930
(1 row)
```

## AGE\_IN\_YEARS

Returns the difference in years between two dates, expressed as an integer.

### Behavior type

- [Immutable](#) if both date arguments are of data type `TIMESTAMP`
- [Stable](#) if either date is a `TIMESTAMPTZ` or only one argument is supplied

### Syntax

```
AGE_IN_YEARS([date1,] date2)
```

### Parameters

#### *date1*

#### *date2*

Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets *date1* to the current date. Both parameters must evaluate to one of the following data types:

- `DATE`
- `TIMESTAMP`
- `TIMESTAMPTZ`

If  $date1 < date2$ , `AGE_IN_YEARS` returns a negative value.

### Examples

Get the age of someone born March 2 1972, as of June 21 1990:

```
=> SELECT AGE_IN_YEARS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
AGE_IN_YEARS
```

```

 18
(1 row)
```

If the first date is earlier than the second date, `AGE_IN_YEARS` returns a negative number:

```
=> SELECT AGE_IN_YEARS('1972-03-02'::TIMESTAMP, '1990-06-21'::TIMESTAMP);
AGE_IN_YEARS
```

```

 -19
(1 row)
```

Get the age of someone who was born November 21 1939, as of today:

```
=> SELECT AGE_IN_YEARS('1939-11-21'::DATE);
AGE_IN_YEARS
```

```

 77
(1 row)
```

## CLOCK\_TIMESTAMP

Returns a value of type `TIMESTAMP WITH TIMEZONE` that represents the current system-clock time.

`CLOCK_TIMESTAMP` uses the date and time supplied by the operating system on the server to which you are connected, which should be the same across all servers. The value changes each time you call it.

### Behavior type

[Volatile](#)

### Syntax

```
CLOCK_TIMESTAMP()
```

#### Examples

The following command returns the current time on your system:

```
SELECT CLOCK_TIMESTAMP() "Current Time";
 Current Time

2010-09-23 11:41:23.33772-04
(1 row)
```

Each time you call the function, you get a different result. The difference in this example is in microseconds:

```
SELECT CLOCK_TIMESTAMP() "Time 1", CLOCK_TIMESTAMP() "Time 2";
 Time 1 | Time 2
-----+-----
2010-09-23 11:41:55.369201-04 | 2010-09-23 11:41:55.369202-04
(1 row)
```

See also

- [STATEMENT\\_TIMESTAMP](#)
- [TRANSACTION\\_TIMESTAMP](#)

#### CURRENT\_DATE

Returns the date (date-type value) on which the current transaction started.

Behavior type

[Stable](#)

Syntax

```
CURRENT_DATE()
```

#### Note

You can call this function without parentheses.

#### Examples

```
SELECT CURRENT_DATE;
 ?column?

2010-09-23
(1 row)
```

#### CURRENT\_TIME

Returns a value of type **TIME WITH TIMEZONE** that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to `CURRENT_TIME` within the same transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
CURRENT_TIME [(precision)]
```

#### Note

If you specify a column label without precision, you must also omit parentheses.

Parameters

***precision***

An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits.

#### Examples

```
=> SELECT CURRENT_TIME(1) AS Time;
 Time

06:51:45.2-07
(1 row)
=> SELECT CURRENT_TIME(5) AS Time;
 Time

06:51:45.18435-07
(1 row)
```

#### CURRENT\_TIMESTAMP

Returns a value of type **TIME WITH TIMEZONE** that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to **CURRENT\_TIMESTAMP** within the same transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
CURRENT_TIMESTAMP (precision)
```

Parameters

***precision***

An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits.

#### Examples

```
=> SELECT CURRENT_TIMESTAMP(1) AS time;
 time

2017-03-27 06:50:49.7-07
(1 row)
=> SELECT CURRENT_TIMESTAMP(5) AS time;
 time

2017-03-27 06:50:49.69967-07
(1 row)
```

#### DATE

Converts the input value to a [DATE](#) data type.

Behavior type

- [Immutable](#) if the input value is a **TIMESTAMP** , **DATE** , **VARCHAR** , or integer
- [Stable](#) if the input value is a **TIMESTAMPTZ**

Syntax

```
DATE (value)
```

Parameters

***value***

The value to convert, one of the following:

- **TIMESTAMP** , **TIMESTAMPTZ** , **VARCHAR** , or another **DATE** .
- Integer: Vertica treats the integer as the number of days since 01/01/0001 and returns the date.

#### Examples

```
=> SELECT DATE (1);
 DATE

0001-01-01
(1 row)

=> SELECT DATE (734260);
 DATE

2011-05-03
(1 row)

=> SELECT DATE('TODAY');
 DATE

2016-12-07
(1 row)
```

See also

- [TO\\_DATE](#)
- [TO\\_TIMESTAMP](#)
- [TO\\_TIMESTAMP\\_TZ](#)

## DATE\_PART

Extracts a sub-field such as year or hour from a date/time expression, equivalent to the the SQL-standard function [EXTRACT](#).

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), or [INTERVAL](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

Syntax

```
DATE_PART ('field', date)
```

Parameters

### *field*

A constant value that specifies the sub-field to extract from *date* (see [Field Values](#) below).

### *date*

The date to process, an expression that evaluates to one of the following data types:

- [DATE](#) (cast to [TIMESTAMP](#))
- [TIMESTAMP/TIMESTAMPTZ](#)
- [INTERVAL](#)

Field values

### **CENTURY**

The century number.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from -1 to 1.

### **DAY**

The day (of the month) field (1–31).

### **DECADE**

The year field divided by 10.

### **DOQ**

The day within the current quarter. DOQ recognizes leap year days.

### **DOW**

Zero-based day of the week, where Sunday=0.

**Note**

**EXTRACT** 's day of week numbering differs from the function [TO\\_CHAR](#).

## DOY

The day of the year (1-365/366)

## EPOCH

Specifies to return one of the following:

- For **DATE** and **TIMESTAMP** values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number).
- For **INTERVAL** values, the total number of seconds in the interval.

## HOUR

The hour field (0-23).

## ISODOW

The ISO day of the week, an integer between 1 and 7 where Monday is 1.

## ISOWEEK

The ISO week of the year, an integer between 1 and 53.

## ISOYEAR

The ISO year.

## MICROSECONDS

The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

## MILLENNIUM

The millennium number, where the first millennium is 1 and each millenium starts on **01-01- y001** . For example, millennium 2 starts on 01-01-1001.

## MILLISECONDS

The seconds field, including fractional parts, multiplied by 1000. This includes full seconds.

## MINUTE

The minutes field (0 - 59).

## MONTH

For **TIMESTAMP** values, the number of the month within the year (1 - 12) ; for **interval** values the number of months, modulo 12 (0 - 11).

## QUARTER

The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for **TIMESTAMP** values.

## SECOND

The seconds field, including fractional parts, 0-59, or 0-60 if the operating system implements leap seconds.

## TIME\_ZONE

The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

## TIMEZONE\_HOUR

The hour component of the time zone offset.

## TIMEZONE\_MINUTE

The minute component of the time zone offset.

## WEEK

The number of the week of the calendar year that the day is in.

## YEAR

The year field. There is no **0 AD** , so subtract **BC** years from **AD** years accordingly.

## Notes

According to the ISO-8601 standard, the week starts on Monday, and the first week of a year contains January 4. Thus, an early January date can sometimes be in the week 52 or 53 of the previous calendar year. For example:

```
=> SELECT YEAR_ISO('01-01-2016'::DATE), WEEK_ISO('01-01-2016'), DAYOFWEEK_ISO('01-01-2016');
YEAR_ISO | WEEK_ISO | DAYOFWEEK_ISO
-----+-----+-----
2015 | 53 | 5
(1 row)
```

## Examples

Extract the day value:

```
SELECT DATE_PART('DAY', TIMESTAMP '2009-02-24 20:38:40') "Day";
 Day

 24
(1 row)
```

Extract the month value:

```
SELECT DATE_PART('MONTH', '2009-02-24 20:38:40'::TIMESTAMP) "Month";
 Month

 2
(1 row)
```

Extract the year value:

```
SELECT DATE_PART('YEAR', '2009-02-24 20:38:40'::TIMESTAMP) "Year";
 Year

2009
(1 row)
```

Extract the hours:

```
SELECT DATE_PART('HOUR', '2009-02-24 20:38:40'::TIMESTAMP) "Hour";
 Hour

 20
(1 row)
```

Extract the minutes:

```
SELECT DATE_PART('MINUTES', '2009-02-24 20:38:40'::TIMESTAMP) "Minutes";
 Minutes

 38
(1 row)
```

Extract the day of quarter (DOQ):

```
SELECT DATE_PART('DOQ', '2009-02-24 20:38:40'::TIMESTAMP) "DOQ";
 DOQ

 55
(1 row)
```

See also

[TO\\_CHAR](#)

[DATE\\_TRUNC](#)

Truncates date and time values to the specified precision. The return value is the same data type as the input value. All fields that are less than the specified precision are set to 0, or to 1 for day and month.

Behavior type

[Stable](#)

Syntax

```
DATE_TRUNC(precision, trunc-target)
```

Parameters

***precision***

A string constant that specifies precision for the truncated value. See [Precision Field Values](#) below. The precision must be valid for the *trunc-target* date or time.

## **trunc-target**

Valid date/time expression.

Precision field values

### **MILLENNIUM**

The millennium number.

### **CENTURY**

The century number.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries.

### **DECADE**

The year field divided by 10.

### **YEAR**

The year field. Keep in mind there is no **0 AD**, so subtract **BC** years from **AD** years with care.

### **QUARTER**

The calendar quarter of the specified date as an integer, where the January-March quarter is 1.

### **MONTH**

For **timestamp** values, the number of the month within the year (1–12); for **interval** values the number of months, modulo 12 (0–11).

### **WEEK**

The number of the week of the year that the day is in.

According to the ISO-8601 standard, the week starts on Monday, and the first week of a year contains January 4. Thus, an early January date can sometimes be in the week 52 or 53 of the previous calendar year. For example:

```
=> SELECT YEAR_ISO('01-01-2016'::DATE), WEEK_ISO('01-01-2016'), DAYOFWEEK_ISO('01-01-2016');
YEAR_ISO | WEEK_ISO | DAYOFWEEK_ISO
-----+-----+-----
2015 | 53 | 5
(1 row)
```

### **DAY**

The day (of the month) field (1–31).

### **HOURL**

The hour field (0–23).

### **MINUTE**

The minutes field (0–59).

### **SECOND**

The seconds field, including fractional parts (0–59) (60 if leap seconds are implemented by the operating system).

### **MILLISECONDS**

The seconds field, including fractional parts, multiplied by 1000. Note that this includes full seconds.

### **MICROSECONDS**

The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

Examples

The following example sets the field value as hour and returns the hour, truncating the minutes and seconds:

```
=> SELECT DATE_TRUNC('HOUR', TIMESTAMP '2012-02-24 13:38:40') AS HOUR;
HOUR

2012-02-24 13:00:00
(1 row)
```

The following example returns the year from the input **timestampz** '2012-02-24 13:38:40'. The function also defaults the month and day to January 1, truncates the hour:minute:second of the timestamp, and appends the time zone ( **-05** ):

```
=> SELECT DATE_TRUNC('YEAR', TIMESTAMPTZ '2012-02-24 13:38:40') AS YEAR;
YEAR
```

```

2012-01-01 00:00:00-05
(1 row)
```

The following example returns the year and month and defaults day of month to 1, truncating the rest of the string:

```
=> SELECT DATE_TRUNC('MONTH', TIMESTAMP '2012-02-24 13:38:40') AS MONTH;
MONTH
```

```

2012-02-01 00:00:00
(1 row)
```

## DATEDIFF

Returns the time span between two dates, in the intervals specified. **DATEDIFF** excludes the start date in its calculation.

### Behavior type

- [Immutable](#) if start and end dates are **TIMESTAMP**, **DATE**, **TIME**, or **INTERVAL**
- [Stable](#) if start and end dates are **TIMESTAMPTZ**

### Syntax

```
DATEDIFF (datepart, start, end);
```

### Parameters

#### **datepart**

Specifies the type of date or time intervals that **DATEDIFF** returns. If *datepart* is an expression, it must be enclosed in parentheses:

```
DATEDIFF(expression, start, end);
```

*datepart* must evaluate to one of the following string literals, either quoted or unquoted:

- **year** | **yy** | **yyyy**
- **quarter** | **qq** | **q**
- **month** | **mm** | **m**
- **day** | **dayofyear** | **dd** | **d** | **dy** | **y**
- **week** | **wk** | **ww**
- **hour** | **hh**
- **minute** | **mi** | **n**
- **second** | **ss** | **s**
- **millisecond** | **ms**
- **microsecond** | **mcs** | **us**

#### **start , end**

Specify the start and end dates, where *start* and *end* evaluate to one of the following data types:

- [TIMESTAMP/TIMESTAMPTZ](#)
- [DATE](#)
- [TIME/TIMETZ](#)
- [INTERVAL](#)

If *end* < *start*, **DATEDIFF** returns a negative value.

#### Note

**TIME** and **INTERVAL** data types are invalid for start and end dates if *datepart* is set to **year**, **quarter**, or **month**.

### Compatible start and end date data types

The following table shows which data types can be matched as start and end dates:

	DATE	TIMESTAMP	TIMESTAMPTZ	TIME	INTERVAL

DATE	.	.	.		
TIMESTAMP	.	.	.		
TIMESTAMPTZ	.	.	.		
TIME				.	
INTERVAL					.

For example, if you set the start date to an **INTERVAL** data type, the end date must also be an **INTERVAL** , otherwise Vertica returns an error:

```
SELECT DATEDIFF(day, INTERVAL '26 days', INTERVAL '1 month');
```

```
datediff
```

```

```

```
4
```

```
(1 row)
```

Date part intervals

**DATEDIFF** uses the *datepart* argument to calculate the number of intervals between two dates, rather than the actual amount of time between them.

**DATEDIFF** uses the following cutoff points to calculate those intervals:

- **year** : January 1
- **quarter** : January 1, April 1, July 1, October 1
- **month** : the first day of the month
- **week** : Sunday at midnight (24:00)

For example, if *datepart* is set to **year** , **DATEDIFF** uses January 01 to calculate the number of years between two dates. The following **DATEDIFF** statement sets *datepart* to **year** , and specifies a time span 01/01/2005 - 06/15/2008:

```
SELECT DATEDIFF(year, '01-01-2005'::date, '12-31-2008'::date);
```

```
datediff
```

```

```

```
3
```

```
(1 row)
```

**DATEDIFF** always excludes the start date when it calculates intervals—in this case, 01/01//2005. **DATEDIFF** considers only calendar year starts in its calculation, so in this case it only counts years 2006, 2007, and 2008. The function returns 3, although the actual time span is nearly four years.

If you change the start and end dates to 12/31/2004 and 01/01/2009, respectively, **DATEDIFF** also counts years 2005 and 2009. This time, it returns 5, although the actual time span is just over four years:

```
=> SELECT DATEDIFF(year, '12-31-2004'::date, '01-01-2009'::date);
```

```
datediff
```

```

```

```
5
```

```
(1 row)
```

Similarly, **DATEDIFF** uses month start dates when it calculates the number of months between two dates. Thus, given the following statement, **DATEDIFF** counts months February through September and returns 8:

```
=> SELECT DATEDIFF(month, '01-31-2005'::date, '09-30-2005'::date);
```

```
datediff
```

```

```

```
8
```

```
(1 row)
```

See also

[TIMESTAMPDIFF](#)

DAY

Returns as an integer the day of the month from the input value.

## Behavior type

- [Immutable](#) if the input value is a **TIMESTAMP** , **DATE** , **VARCHAR** , or **INTEGER**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

## Syntax

```
DAY (value)
```

## Parameters

### **value**

The value to convert, one of the following: **TIMESTAMP** , **TIMESTAMPTZ** , **INTERVAL** , **VARCHAR** , or **INTEGER** .

## Examples

```
=> SELECT DAY (6);
```

```
DAY
```

```

6
```

```
(1 row)
```

```
=> SELECT DAY(TIMESTAMP 'sep 22, 2011 12:34');
```

```
DAY
```

```

22
```

```
(1 row)
```

```
=> SELECT DAY('sep 22, 2011 12:34');
```

```
DAY
```

```

22
```

```
(1 row)
```

```
=> SELECT DAY(INTERVAL '35 12:34');
```

```
DAY
```

```

35
```

```
(1 row)
```

## DAYOFMONTH

Returns the day of the month as an integer.

## Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP** , **DATE** , or **VARCHAR**
- [Stable](#) if the target date is a **TIMESTAMPTZ**

## Syntax

```
DAYOFMONTH (date)
```

## Parameters

### **date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

## Examples

```
=> SELECT DAYOFMONTH (TIMESTAMP 'sep 22, 2011 12:34');
```

```
DAYOFMONTH
```

```

 22
```

```
(1 row)
```

## DAYOFWEEK

Returns the day of the week as an integer, where Sunday is day 1.

### Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the target date is a **TIMESTAMPTZ**

### Syntax

```
DAYOFWEEK (date)
```

### Parameters

#### **date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

### Examples

```
=> SELECT DAYOFWEEK (TIMESTAMP 'sep 17, 2011 12:34');
```

```
DAYOFWEEK
```

```

 7
```

```
(1 row)
```

## DAYOFWEEK\_ISO

Returns the ISO 8061 day of the week as an integer, where Monday is day 1.

### Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the target date is a **TIMESTAMPTZ**

### Syntax

```
DAYOFWEEK_ISO (date)
```

### Parameters

#### **date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

### Examples

```
=> SELECT DAYOFWEEK_ISO(TIMESTAMP 'Sep 22, 2011 12:34');
```

```
DAYOFWEEK_ISO
```

```

 4
```

```
(1 row)
```

The following example shows how to combine the `DAYOFWEEK_ISO`, `WEEK_ISO`, and `YEAR_ISO` functions to find the ISO day of the week, week, and year:

```
=> SELECT DAYOFWEEK_ISO('Jan 1, 2000'), WEEK_ISO('Jan 1, 2000'), YEAR_ISO('Jan1,2000');
DAYOFWEEK_ISO | WEEK_ISO | YEAR_ISO
```

```
-----+-----+-----
 6 | 52 | 1999
```

(1 row)

See also

- [WEEK\\_ISO](#)
- [DAYOFWEEK\\_ISO](#)
- [http://en.wikipedia.org/wiki/ISO\\_8601](http://en.wikipedia.org/wiki/ISO_8601)

## DAYOFYEAR

Returns the day of the year as an integer, where January 1 is day 1.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP** , **DATE** , or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
DAYOFYEAR (date)
```

Parameters

**date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT DAYOFYEAR (TIMESTAMP 'SEPT 22,2011 12:34');
DAYOFYEAR
```

```

 265
(1 row)
```

## DAYS

Returns the integer value of the specified date, where 1 AD is 1. If the date precedes 1 AD, **DAYS** returns a negative integer.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP** , **DATE** , or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
DAYS (date)
```

Parameters

**date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

```
=> SELECT DAYS (DATE '2011-01-22');
```

```
DAYS
```

```

```

```
734159
```

```
(1 row)
```

```
=> SELECT DAYS (DATE 'March 15, 0044 BC');
```

```
DAYS
```

```

```

```
-15997
```

```
(1 row)
```

## EXTRACT

Retrieves sub-fields such as year or hour from date/time values and returns values of type [NUMERIC](#). **EXTRACT** is intended for computational processing, rather than for formatting date/time values for display.

### Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), or [INTERVAL](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

### Syntax

```
EXTRACT (field FROM date)
```

### Parameters

#### **field**

A constant value that specifies the sub-field to extract from *date* (see [Field Values](#) below).

#### **date**

The date to process, an expression that evaluates to one of the following data types:

- [DATE](#) (cast to [TIMESTAMP](#))
- [TIMESTAMP/TIMESTAMPTZ](#)
- [INTERVAL](#)

### Field values

#### **CENTURY**

The century number.

The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from -1 to 1.

#### **DAY**

The day (of the month) field (1–31).

#### **DECADE**

The year field divided by 10.

#### **DOQ**

The day within the current quarter. DOQ recognizes leap year days.

#### **DOW**

Zero-based day of the week, where Sunday=0.

#### Note

**EXTRACT**'s day of week numbering differs from the function [TO\\_CHAR](#).

#### **DOY**

The day of the year (1–365/366)

#### **EPOCH**

Specifies to return one of the following:

- For [DATE](#) and [TIMESTAMP](#) values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number).
- For [INTERVAL](#) values, the total number of seconds in the interval.

**HOUR**

The hour field (0–23).

**ISODOW**

The ISO day of the week, an integer between 1 and 7 where Monday is 1.

**ISOWEEK**

The ISO week of the year, an integer between 1 and 53.

**ISOYEAR**

The ISO year.

**MICROSECONDS**

The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

**MILLENNIUM**

The millennium number, where the first millennium is 1 and each millenium starts on **01-01- y001** . For example, millennium 2 starts on 01-01-1001.

**MILLISECONDS**

The seconds field, including fractional parts, multiplied by 1000. This includes full seconds.

**MINUTE**

The minutes field (0 - 59).

**MONTH**

For **TIMESTAMP** values, the number of the month within the year (1 - 12) ; for **interval** values the number of months, modulo 12 (0 - 11).

**QUARTER**

The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for **TIMESTAMP** values.

**SECOND**

The seconds field, including fractional parts, 0–59, or 0-60 if the operating system implements leap seconds.

**TIME\_ZONE**

The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.

**TIMEZONE\_HOUR**

The hour component of the time zone offset.

**TIMEZONE\_MINUTE**

The minute component of the time zone offset.

**WEEK**

The number of the week of the calendar year that the day is in.

**YEAR**

The year field. There is no **0 AD** , so subtract **BC** years from **AD** years accordingly.

**Examples**

Extract the day of the week and day in quarter from the current **TIMESTAMP**:

```

=> SELECT CURRENT_TIMESTAMP AS NOW;
 NOW

2016-05-03 11:36:08.829004-04
(1 row)
=> SELECT EXTRACT (DAY FROM CURRENT_TIMESTAMP);
 date_part

 3
(1 row)
=> SELECT EXTRACT (DOQ FROM CURRENT_TIMESTAMP);
 date_part

 33
(1 row)

```

Extract the timezone hour from the current time:

```
=> SELECT CURRENT_TIMESTAMP;
 ?column?
```

```

2016-05-03 11:36:08.829004-04
```

```
(1 row)
```

```
=> SELECT EXTRACT(TIMEZONE_HOUR FROM CURRENT_TIMESTAMP);
date_part
```

```

-4
```

```
(1 row)
```

Extract the number of seconds since 01-01-1970 00:00:

```
=> SELECT EXTRACT(EPOCH FROM '2001-02-16 20:38:40-08'::TIMESTAMPTZ);
date_part
```

```

982384720.000000
```

```
(1 row)
```

Extract the number of seconds between 01-01-1970 00:00 and 5 days 3 hours before:

```
=> SELECT EXTRACT(EPOCH FROM '-5 days 3 hours'::INTERVAL);
date_part
```

```

-442800.000000
```

```
(1 row)
```

Convert the results from the last example to a `TIMESTAMP`:

```
=> SELECT 'EPOCH'::TIMESTAMPTZ -442800 * '1 second'::INTERVAL;
 ?column?
```

```

1969-12-26 16:00:00-05
```

```
(1 row)
```

## GETDATE

Returns the current statement's start date and time as a `TIMESTAMP` value. This function is identical to [SYSDATE](#).

`GETDATE` uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers.

Internally, `GETDATE` converts [STATEMENT\\_TIMESTAMP](#) from `TIMESTAMPTZ` to `TIMESTAMP`.

Behavior type

[Stable](#)

Syntax

```
GETDATE()
```

Examples

```
=> SELECT GETDATE();
 GETDATE
```

```

2011-03-07 13:21:29.497742
```

```
(1 row)
```

See also

[Date/time expressions](#)

`GETUTCDATE`

Returns the current statement's start date and time as a `TIMESTAMP` value.

`GETUTCDATE` uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, `GETUTCDATE` converts [STATEMENT\\_TIMESTAMP](#) at TIME ZONE 'UTC'.

Behavior type

[Stable](#)

Syntax

```
GETUTCDATE()
```

Examples

```
=> SELECT GETUTCDATE();
 GETUTCDATE

2011-03-07 20:20:26.193052
(1 row)
```

See also

- [Date/time expressions](#)

HOUR

Returns the hour portion of the specified date as an integer, where 0 is 00:00 to 00:59.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
HOUR(date)
```

Parameters

***date***

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
  
- [INTERVAL](#)

Examples

```
=> SELECT HOUR (TIMESTAMP 'sep 22, 2011 12:34');
 HOUR

 12
(1 row)
=> SELECT HOUR (INTERVAL '35 12:34');
 HOUR

 12
(1 row)
=> SELECT HOUR ('12:34');
 HOUR

 12
(1 row)
```

ISFINITE

Tests for the special **TIMESTAMP** constant **INFINITY** and returns a value of type **BOOLEAN**.

Behavior type

[Immutable](#)

Syntax

```
ISFINITE (timestamp)
```

## Parameters

### **timestamp**

Expression of type `TIMESTAMP`

## Examples

```
SELECT ISFINITE(TIMESTAMP '2009-02-16 21:28:30');
ISFINITE

t
(1 row)
SELECT ISFINITE(TIMESTAMP 'INFINITY');
ISFINITE

f
(1 row)
```

## JULIAN\_DAY

Returns the integer value of the specified day according to the Julian calendar, where day 1 is the first day of the Julian period, January 1, 4713 BC (on the Gregorian calendar, November 24, 4714 BC).

## Behavior type

- [Immutable](#) if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- [Stable](#) if the specified date is a `TIMESTAMPTZ`

## Syntax

```
JULIAN_DAY (date)
```

## Parameters

### **date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

## Examples

```
=> SELECT JULIAN_DAY (DATE 'MARCH 15, 0044 BC');
JULIAN_DAY

1705428
(1 row)
=> SELECT JULIAN_DAY (DATE '2001-01-01');
JULIAN_DAY

2451911
(1 row)
```

## LAST\_DAY

Returns the last day of the month in the specified date.

## Behavior type

- [Immutable](#) if the specified is a `TIMESTAMP` or `DATE`
- [Stable](#) if the specified date is a `TIMESTAMPTZ`

## Syntax

```
LAST_DAY (date)
```

## Parameters

## date

The date to process, one of the following data types:

- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Calculating first day of month

SQL does not support any function that returns the first day in the month of a given date. You must use other functions to work around this limitation. For example:

```
=> SELECT DATE ('2022/07/04') - DAYOFMONTH ('2022/07/04') +1;
?column?

2022-07-01
(1 row)

=> SELECT LAST_DAY('1929/06/06') - (SELECT DAY(LAST_DAY('1929/06/06'))-1);
?column?

1929-06-01
(1 row)
```

Examples

The following example returns the last day of February as 29 because 2016 is a leap year:

```
=> SELECT LAST_DAY('2016-02-28 23:30 PST') "Last Day";
Last Day

2016-02-29
(1 row)
```

The following example returns the last day of February in a non-leap year:

```
> SELECT LAST_DAY('2017/02/03') "Last";
Last

2017-02-28
(1 row)
```

The following example returns the last day of March, after converting the string value to the specified DATE type:

```
=> SELECT LAST_DAY('2003/03/15') "Last";
Last

2012-03-31
(1 row)
```

## LOCALTIME

Returns a value of type **TIME** that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to **LOCALTIME** within the same transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
LOCALTIME [(precision)]
```

Parameters

***precision***

Rounds the result to the specified number of fractional digits in the seconds field.

Examples

```

=> CREATE TABLE t1 (a int, b int);
CREATE TABLE

=> INSERT INTO t1 VALUES (1,2);
OUTPUT

 1
(1 row)

=> SELECT LOCALTIME time;
 time

15:03:14.595296
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT

 1
(1 row)

=> SELECT LOCALTIME;
 time

15:03:14.595296
(1 row)

=> COMMIT;
COMMIT

=> SELECT LOCALTIME;
 time

15:03:49.738032
(1 row)

```

## LOCALTIMESTAMP

Returns a value of type [TIMESTAMP/TIMESTAMPZ](#) that represents the start of the current transaction, and remains unchanged until the transaction is closed. Thus, multiple calls to LOCALTIMESTAMP within a given transaction return the same timestamp.

Behavior type

[Stable](#)

Syntax

```
LOCALTIMESTAMP [(precision)]
```

Parameters

***precision***

Rounds the result to the specified number of fractional digits in the seconds field.

Examples

```
=> CREATE TABLE t1 (a int, b int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1,2);
OUTPUT
```

```

1
(1 row)
```

```
=> SELECT LOCALTIMESTAMP(2) AS 'local timestamp';
local timestamp
```

```

2021-03-05 10:48:58.26
(1 row)
```

```
=> INSERT INTO t1 VALUES (3,4);
OUTPUT
```

```

1
(1 row)
```

```
=> SELECT LOCALTIMESTAMP(2) AS 'local timestamp';
local timestamp
```

```

2021-03-05 10:48:58.26
(1 row)
```

```
=> COMMIT;
COMMIT
```

```
=> SELECT LOCALTIMESTAMP(2) AS 'local timestamp';
local timestamp
```

```

2021-03-05 10:50:08.99
(1 row)
```

## MICROSECOND

Returns the microsecond portion of the specified date as an integer.

### Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [INTERVAL](#), or [VARCHAR](#)
- [Stable](#) if the specified date is a [TIMESTAMP TZ](#)

### Syntax

```
MICROSECOND (date)
```

### Parameters

#### *date*

The date to process, one of the following data types:

- [VARCHAR](#)
- [TIMESTAMP](#)
- [TIMESTAMP TZ](#)
- [INTERVAL](#)

### Examples

```
=> SELECT MICROSECOND (TIMESTAMP 'Sep 22, 2011 12:34:01.123456');
MICROSECOND
```

```

123456
(1 row)
```

## MIDNIGHT\_SECONDS

Within the specified date, returns the number of seconds between midnight and the date's time portion.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
MIDNIGHT_SECONDS (date)
```

Parameters

**date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

Examples

Get the number of seconds since midnight:

```
=> SELECT MIDNIGHT_SECONDS(CURRENT_TIMESTAMP);
MIDNIGHT_SECONDS

 36480
(1 row)
```

Get the number of seconds between midnight and noon on March 3 2016:

```
=> SELECT MIDNIGHT_SECONDS('3-3-2016 12:00'::TIMESTAMP);
MIDNIGHT_SECONDS

 43200
(1 row)
```

MINUTE

Returns the minute portion of the specified date as an integer.

Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, **VARCHAR** or **INTERVAL**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

Syntax

```
MINUTE (date)
```

Parameters

**date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
- [INTERVAL](#)

Examples

```
=> SELECT MINUTE('12:34:03.456789');
```

```
MINUTE
```

```

34
```

```
(1 row)
```

```
=> SELECT MINUTE (TIMESTAMP 'sep 22, 2011 12:34');
```

```
MINUTE
```

```

34
```

```
(1 row)
```

```
=> SELECT MINUTE(INTERVAL '35 12:34:03.456789');
```

```
MINUTE
```

```

34
```

```
(1 row)
```

## MONTH

Returns the month portion of the specified date as an integer.

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), [VARCHAR](#) or [INTERVAL](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

Syntax

```
MONTH (date)
```

Parameters

**date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
- [INTERVAL](#)

Examples

In the following examples, Vertica returns the month portion of the specified string. For example, '6-9' represent September 6.

```
=> SELECT MONTH('6-9');
```

```
MONTH
```

```

9
```

```
(1 row)
```

```
=> SELECT MONTH (TIMESTAMP 'sep 22, 2011 12:34');
```

```
MONTH
```

```

9
```

```
(1 row)
```

```
=> SELECT MONTH(INTERVAL '2-35' year to month);
```

```
MONTH
```

```

11
```

```
(1 row)
```

## MONTHS\_BETWEEN

Returns the number of months between two dates. [MONTHS\\_BETWEEN](#) can return an integer or a [FLOAT](#):

- Integer: The day portions of *date1* and *date2* are the same, and neither date is the last day of the month. **MONTHS\_BETWEEN** also returns an integer if both dates in *date1* and *date2* are the last days of their respective months. For example, **MONTHS\_BETWEEN** calculates the difference between April 30 and March 31 as 1 month.
- FLOAT: The day portions of *date1* and *date2* are different and one or both dates are not the last day of their respective months. For example, the difference between April 2 and March 1 is 1.03225806451613 . To calculate month fractions, **MONTHS\_BETWEEN** assumes all months contain 31 days.

**MONTHS\_BETWEEN** disregards timestamp time portions.

Behavior type

- [Immutable](#) if both date arguments are of data type **TIMESTAMP** or **DATE**
- [Stable](#) if either date is a **TIMESTAMPTZ**

Syntax

```
MONTHS_BETWEEN (date1 , date2);
```

Parameters

**date1**

**date2**

Specify the dates to evaluate where *date1* and *date2* evaluate to one of the following data types:

- **DATE**
- **TIMESTAMP**
- **TIMESTAMPTZ**

If *date1* < *date2* , **MONTHS\_BETWEEN** returns a negative value.

Examples

Return the number of months between April 7 2016 and January 7 2015:

```
=> SELECT MONTHS_BETWEEN ('04-07-16'::TIMESTAMP, '01-07-15'::TIMESTAMP);
MONTHS_BETWEEN

 15
(1 row)
```

Return the number of months between March 31 2016 and February 28 2016 ( **MONTHS\_BETWEEN** assumes both months contain 31 days):

```
=> SELECT MONTHS_BETWEEN ('03-31-16'::TIMESTAMP, '02-28-16'::TIMESTAMP);
MONTHS_BETWEEN

1.09677419354839
(1 row)
```

Return the number of months between March 31 2016 and February 29 2016:

```
=> SELECT MONTHS_BETWEEN ('03-31-16'::TIMESTAMP, '02-29-16'::TIMESTAMP);
MONTHS_BETWEEN

 1
(1 row)
```

**NEW\_TIME**

Converts a timestamp value from one time zone to another and returns a **TIMESTAMP**.

Behavior type

[Immutable](#)

Syntax

```
NEW_TIME('timestamp' , 'timezone1' , 'timezone2')
```

Parameters

**timestamp**

The timestamp to convert, conforms to one of the following formats:

- [TIMESTAMP](#) / [TIMESTAMPTZ](#)
- [DATE](#)
- Character string that can be converted to a [TIMESTAMP](#) —for example, [May 24, 2012 10:00](#) .

### **timezone1**

**\*timezone2\***

Specify the source and target timezones, one of the strings defined in `/opt/vertica/share/timezonesets` . For example:

- [GMT](#) : Greenwich Mean Time
- [AST](#) / [ADT](#) : Atlantic Standard/Daylight Time
- [EST](#) / [EDT](#) : Eastern Standard/Daylight Time
- [CST](#) / [CDT](#) : Central Standard/Daylight Time
- [MST](#) / [MDT](#) : Mountain Standard/Daylight Time
- [PST](#) / [PDT](#) : Pacific Standard/Daylight Time

### Examples

Convert the specified time from Eastern Standard Time (EST) to Pacific Standard Time (PST):

```
=> SELECT NEW_TIME('05-24-12 13:48:00', 'EST', 'PST');
NEW_TIME

2012-05-24 10:48:00
(1 row)
```

Convert 1:00 AM January 2012 from EST to PST:

```
=> SELECT NEW_TIME('01-01-12 01:00:00', 'EST', 'PST');
NEW_TIME

2011-12-31 22:00:00
(1 row)
```

Convert the current time EST to PST:

```
=> SELECT NOW();
NOW

2016-12-09 10:30:36.727307-05
(1 row)

=> SELECT NEW_TIME('NOW', 'EDT', 'CDT');
NEW_TIME

2016-12-09 09:30:36.727307
(1 row)
```

The following example returns the year 45 before the Common Era in Greenwich Mean Time and converts it to Newfoundland Standard Time:

```
=> SELECT NEW_TIME('April 1, 45 BC', 'GMT', 'NST')::DATE;
NEW_TIME

0045-03-31 BC
(1 row)
```

### NEXT\_DAY

Returns the date of the first instance of a particular day of the week that follows the specified date.

#### Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#) , [DATE](#) , or [VARCHAR](#)
- [Stable](#) if the specified date is a [TIMESTAMPTZ](#)

#### Syntax

```
NEXT_DAY('date', 'day-string')
```

## Parameters

### *date*

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

### *day-string*

The day of the week to process, a CHAR or VARCHAR string or character constant. Supply the full English name such as Tuesday, or any conventional abbreviation, such as Tue or Tues. *day-string* is not case sensitive and trailing spaces are ignored.

## Examples

Get the date of the first Monday that follows April 29 2016:

```
=> SELECT NEXT_DAY('4-29-2016'::TIMESTAMP,'Monday') "NEXT DAY" ;
NEXT DAY

2016-05-02
(1 row)
```

Get the first Tuesday that follows today:

```
SELECT NEXT_DAY(CURRENT_TIMESTAMP,'tues') "NEXT DAY" ;
NEXT DAY

2016-05-03
(1 row)
```

## NOW [date/time]

Returns a value of type [TIMESTAMP WITH TIME ZONE](#) representing the start of the current transaction. NOW is equivalent to [CURRENT\\_TIMESTAMP](#) except that it does not accept a precision parameter.

The return value does not change during the transaction. Thus, multiple calls to [CURRENT\\_TIMESTAMP](#) within the same transaction return the same timestamp.

## Behavior type

[Stable](#)

## Syntax

```
NOW()
```

## Examples

```

=> CREATE TABLE t1 (a int, b int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1,2);
OUTPUT

 1
(1 row)

=> SELECT NOW();
 NOW

2016-12-09 13:00:08.74685-05
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT

 1
(1 row)

=> SELECT NOW();
 NOW

2016-12-09 13:00:08.74685-05
(1 row)

=> COMMIT;
COMMIT
dbadmin=> SELECT NOW();
 NOW

2016-12-09 13:01:31.420624-05
(1 row)

```

## OVERLAPS

Evaluates two time periods and returns true when they overlap, false otherwise.

### Behavior type

- [Stable](#) when **TIMESTAMP** and **TIMESTAMPtz** are both used, or when **TIMESTAMPtz** is used with **INTERVAL**
- [Immutable](#) otherwise

### Syntax

```

(start, end) OVERLAPS (start, end)
(start, interval) OVERLAPS (start, interval)

```

### Parameters

- start**  
**DATE** , **TIME** , or **TIMESTAMP** / **TIMESTAMPtz** value that specifies the beginning of a time period.
- end**  
**DATE** , **TIME** , or **TIMESTAMP** / **TIMESTAMPtz** value that specifies the end of a time period.
- interval**  
Value that specifies the length of the time period.

### Examples

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Oct 10 2008 - Oct 3 2016 overlap:

```
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-10-30', DATE '2016-10-30');
overlaps

t
(1 row)
```

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Jan 01 - Oct 30 2008 - Oct 3, 2016 overlap:

```
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-01-30', DATE '2008-10-30');
overlaps

f
(1 row)
```

Evaluate whether date range Feb 02 2016 + 1 week overlaps with date range Oct 16 2016 - 8 months:

```
=> SELECT (DATE '2016-02-16', INTERVAL '1 week') OVERLAPS (DATE '2016-10-16', INTERVAL '-8 months');
overlaps

t
(1 row)
```

## QUARTER

Returns calendar quarter of the specified date as an integer, where the January-March quarter is 1.

### Syntax

```
QUARTER (date)
```

### Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**.
- [Stable](#) if the specified date is a **TIMESTAMPTZ**.

### Parameters

#### **date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

### Examples

```
=> SELECT QUARTER (TIMESTAMP 'sep 22, 2011 12:34');
QUARTER

3
(1 row)
```

## ROUND

Rounds the specified date or time. If you omit the precision argument, **ROUND** rounds to day (**DD**) precision.

### Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP** or **DATE**.
- [Stable](#) if the target date is a **TIMESTAMPTZ**.

### Syntax

```
ROUND(rounding-target [, 'precision'])
```

### Parameters

#### \* **rounding-target** \*

An expression that evaluates to one of the following data types:

- [DATE](#)
- [TIMESTAMP/TIMESTAMPTZ](#)
- [TIMESTAMPTZ](#)

### precision

A string constant that specifies precision for the rounded value, one of the following:

- **Century** : `CC` | `SCC`
- **Year** : `SYYY` | `YYYY` | `YEAR` | `YYY` | `YY` | `Y`
- **ISO Year** : `IYYY` | `IYY` | `IY` | `I`
- **Quarter** : `Q`
- **Month** : `MONTH` | `MON` | `MM` | `RM`
- **Same weekday as first day of year** : `WW`
- **Same weekday as first day of ISO year** : `IW`
- **Same weekday as first day of month** : `W`
- **Day** (default): `DDD` | `DD` | `J`
- **First weekday** : `DAY` | `DY` | `D`
- **Hour** : `HH` | `HH12` | `HH24`
- **Minute** : `MI`
- **Second** : `SS`

### Note

Hour, minute, and second rounding is not supported by `DATE` expressions.

### Examples

Round to the nearest hour:

```
=> SELECT ROUND(CURRENT_TIMESTAMP, 'HH');
 ROUND

2016-04-28 15:00:00
(1 row)
```

Round to the nearest month:

```
=> SELECT ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
 ROUND

2011-10-01 00:00:00
(1 row)
```

See also

[TIMESTAMP\\_ROUND](#)

`SECOND`

Returns the seconds portion of the specified date as an integer.

Syntax

```
SECOND (date)
```

Behavior type

[Immutable](#), except for `TIMESTAMPTZ` arguments where it is [stable](#).

Parameters

**date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
- [INTERVAL](#)

Examples

```
=> SELECT SECOND ('23:34:03.456789');
```

```
SECOND
```

```

3
```

```
(1 row)
```

```
=> SELECT SECOND (TIMESTAMP 'sep 22, 2011 12:34');
```

```
SECOND
```

```

0
```

```
(1 row)
```

```
=> SELECT SECOND (INTERVAL '35 12:34:03.456789');
```

```
SECOND
```

```

3
```

```
(1 row)
```

## STATEMENT\_TIMESTAMP

Similar to [TRANSACTION\\_TIMESTAMP](#), returns a value of type **TIMESTAMP WITH TIME ZONE** that represents the start of the current statement.

The return value does not change during statement execution. Thus, different stages of statement execution always have the same timestamp.

Behavior type

[Stable](#)

Syntax

```
STATEMENT_TIMESTAMP()
```

Examples

```
=> SELECT foo, bar FROM (SELECT STATEMENT_TIMESTAMP() AS foo)foo, (SELECT STATEMENT_TIMESTAMP() as bar)bar;
```

```
 foo | bar
```

```
-----+-----
```

```
2016-12-07 14:55:51.543988-05 | 2016-12-07 14:55:51.543988-05
```

```
(1 row)
```

See also

- [CLOCK\\_TIMESTAMP](#)
- [TRANSACTION\\_TIMESTAMP](#)

## SYSDATE

Returns the current statement's start date and time as a **TIMESTAMP** value. This function is identical to [GETDATE](#).

**SYSDATE** uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers.

Internally, [GETDATE](#) converts [STATEMENT\\_TIMESTAMP](#) from **TIMESTAMPPTZ** to **TIMESTAMP**.

Behavior type

[Stable](#)

Syntax

```
SYSDATE()
```

### Note

You can call this function with no parentheses.

Examples

```
=> SELECT SYSDATE;
```

```
 sysdate
```

```

```

```
2016-12-12 06:11:10.699642
```

```
(1 row)
```

See also

[Date/time expressions](#)

TIME\_SLICE

Aggregates data by different fixed-time intervals and returns a rounded-up input **TIMESTAMP** value to a value that corresponds with the start or end of the time slice interval.

Given an input **TIMESTAMP** value such as **2000-10-28 00:00:01** , the start time of a 3-second time slice interval is **2000-10-28 00:00:00** , and the end time of the same time slice is **2000-10-28 00:00:03** .

Behavior type

[Immutable](#)

Syntax

```
TIME_SLICE(expression, slice-length [, 'time-unit ' [, 'start-or-end']])
```

Parameters

#### **expression**

One of the following:

- Column of type **TIMESTAMP**
- String constant that can be parsed into a **TIMESTAMP** value. For example:  
'2004-10-19 10:23:54'

Vertica evaluates *expression* on each row.

#### **slice-length**

A positive integer that specifies the slice length.

#### **time-unit**

Time unit of the slice, one of the following:

- **HOUR**
- **MINUTE**
- **SECOND** (default)
- **MILLISECOND**
- **MICROSECOND**

#### **start-or-end**

Specifies whether the returned value corresponds to the start or end time with one of the following strings:

- **START** (default)
- **END**

#### Note

This parameter can be included only if you also supply a non-null *time-unit* argument.

Null argument handling

**TIME\_SLICE** handles null arguments as follows:

- **TIME\_SLICE** returns an error when any one of *slice-length* , *time-unit* , or *start-or-end* parameters is null.
- If *expression* is null and *\*slice-length \** , *\*time-unit \** , or *\*start-or-end \** contain legal values, **TIME\_SLICE** returns a NULL value instead of an error.

Usage

The following command returns the (default) start time of a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3);
 TIME_SLICE

2009-09-19 00:00:00
(1 row)
```

The following command returns the end time of a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'SECOND', 'END');
 TIME_SLICE

2009-09-19 00:00:03
(1 row)
```

This command returns results in milliseconds, using a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'ms');
 TIME_SLICE

2009-09-19 00:00:00.999
(1 row)
```

This command returns results in microseconds, using a 9-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'us');
 TIME_SLICE

2009-09-19 00:00:00.999999
(1 row)
```

The next example uses a 3-second interval with an input value of '00:00:01'. To focus specifically on seconds, the example omits date, though all values are implied as being part of the timestamp with a given input of '00:00:01':

- '00:00: **00** ' is the start of the 3-second time slice
- '00:00: **03** ' is the end of the 3-second time slice.
- '00:00:03' is also the start of the *second* 3-second time slice. In time slice boundaries, the end value of a time slice does not belong to that time slice; it starts the next one.

When the time slice interval is not a factor of 60 seconds, such as a given slice length of 9 in the following example, the slice does not always start or end on 00 seconds:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9);
 TIME_SLICE

2009-02-14 20:12:54
(1 row)
```

This is expected behavior, as the following properties are true for all time slices:

- Equal in length
- Consecutive (no gaps between them)
- Non-overlapping

To force the above example ('2009-02-14 20:13:01') to start at '2009-02-14 20:13:00', adjust the output timestamp values so that the remainder of 54 counts up to 60:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9)+'6 seconds'::INTERVAL AS time;
 time

2009-02-14 20:13:00
(1 row)
```

Alternatively, you could use a different slice length, which is divisible by 60, such as 5:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 5);
 TIME_SLICE

2009-02-14 20:13:00
(1 row)
```

A TIMESTAMPTZ value is implicitly cast to TIMESTAMP. For example, the following two statements have the same effect.

```
=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestampz, 3);
```

```
TIME_SLICE
```

```

2009-09-23 11:12:00
```

```
(1 row)
```

```
=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestampz::timestamp, 3);
```

```
TIME_SLICE
```

```

2009-09-23 11:12:00
```

```
(1 row)
```

## Examples

You can use the SQL analytic functions [FIRST\\_VALUE](#) and [LAST\\_VALUE](#) to find the first/last price within each time slice group (set of rows belonging to the same time slice). This structure can be useful if you want to sample input data by choosing one row from each time slice group.

```
=> SELECT date_key, transaction_time, sales_dollar_amount, TIME_SLICE(DATE '2000-01-01' + date_key + transaction_time, 3),
FIRST_VALUE(sales_dollar_amount)
OVER (PARTITION BY TIME_SLICE(DATE '2000-01-01' + date_key + transaction_time, 3)
ORDER BY DATE '2000-01-01' + date_key + transaction_time) AS first_value
FROM store.store_sales_fact
LIMIT 20;
```

```
date_key | transaction_time | sales_dollar_amount | time_slice | first_value
```

```
-----+-----+-----+-----+-----
1 | 00:41:16 | 164 | 2000-01-02 00:41:15 | 164
1 | 00:41:33 | 310 | 2000-01-02 00:41:33 | 310
1 | 15:32:51 | 271 | 2000-01-02 15:32:51 | 271
1 | 15:33:15 | 419 | 2000-01-02 15:33:15 | 419
1 | 15:33:44 | 193 | 2000-01-02 15:33:42 | 193
1 | 16:36:29 | 466 | 2000-01-02 16:36:27 | 466
1 | 16:36:44 | 250 | 2000-01-02 16:36:42 | 250
2 | 03:11:28 | 39 | 2000-01-03 03:11:27 | 39
3 | 03:55:15 | 375 | 2000-01-04 03:55:15 | 375
3 | 11:58:05 | 369 | 2000-01-04 11:58:03 | 369
3 | 11:58:24 | 174 | 2000-01-04 11:58:24 | 174
3 | 11:58:52 | 449 | 2000-01-04 11:58:51 | 449
3 | 19:01:21 | 201 | 2000-01-04 19:01:21 | 201
3 | 22:15:05 | 156 | 2000-01-04 22:15:03 | 156
4 | 13:36:57 | -125 | 2000-01-05 13:36:57 | -125
4 | 13:37:24 | -251 | 2000-01-05 13:37:24 | -251
4 | 13:37:54 | 353 | 2000-01-05 13:37:54 | 353
4 | 13:38:04 | 426 | 2000-01-05 13:38:03 | 426
4 | 13:38:31 | 209 | 2000-01-05 13:38:30 | 209
5 | 10:21:24 | 488 | 2000-01-06 10:21:24 | 488
```

```
(20 rows)
```

**TIME\_SLICE** rounds the transaction time to the 3-second slice length.

The following example uses the [analytic \(window\) OVER clause](#) to return the last trading price (the last row ordered by TickTime) in each 3-second time slice partition:

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), LAST_VALUE(price)OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING);
```

## Note

If you omit the windowing clause from an analytic clause, **LAST\_VALUE** defaults to **RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW**. Results can seem non-intuitive, because instead of returning the value from the bottom of the current partition, the function returns the bottom of the *window*, which continues to change along with the current input row that is being processed. For more information,

see [Time series analytics](#) and [SQL analytics](#).

In the next example, **FIRST\_VALUE** is evaluated once for each input record and the data is sorted by ascending values. Use **SELECT DISTINCT** to remove the duplicates and return only one output record per **TIME\_SLICE** :

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), FIRST_VALUE(price)OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ASC)
FROM tick_store;
 TIME_SLICE | ?column?
-----+-----
2009-09-21 00:00:06 | 20.00
2009-09-21 00:00:09 | 30.00
2009-09-21 00:00:00 | 10.00
(3 rows)
```

The information output by the above query can also return **MIN** , **MAX** , and **AVG** of the trading prices within each time slice.

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3),FIRST_VALUE(Price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ASC),
 MIN(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
 MAX(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
 AVG(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3))
FROM tick_store;
```

## TIMEOFDAY

Returns the wall-clock time as a text string. Function results advance during transactions.

Behavior type

[Volatile](#)

Syntax

```
TIMEOFDAY()
```

Examples

```
=> SELECT TIMEOFDAY();
 TIMEOFDAY

Mon Dec 12 08:18:01.022710 2016 EST
(1 row)
```

## TIMESTAMP\_ROUND

Rounds the specified **TIMESTAMP**. If you omit the precision argument, **TIMESTAMP\_ROUND** rounds to day ( **DD** ) precision.

Behavior type

- [Immutable](#) if the target date is a **TIMESTAMP**
- [Stable](#) if the target date is a **TIMESTAMPZ**

Syntax

```
TIMESTAMP_ROUND (rounding-target [, 'precision'])
```

Parameters

### rounding-target

An expression that evaluates to one of the following data types:

- [TIMESTAMP/TIMESTAMPTZ](#)
- [TIMESTAMPTZ](#)

### precision

A string constant that specifies precision for the rounded value, one of the following:

- **Century** : [CC](#) | [SCC](#)
- **Year** : [SYYY](#) | [YYYY](#) | [YEAR](#) | [YYY](#) | [YY](#) | [Y](#)
- **ISO Year** : [IYYY](#) | [IYY](#) | [IY](#) | [I](#)
- **Quarter** : [Q](#)
- **Month** : [MONTH](#) | [MON](#) | [MM](#) | [RM](#)
- **Same weekday as first day of year** : [WW](#)
- **Same weekday as first day of ISO year** : [IW](#)
- **Same weekday as first day of month** : [W](#)
- **Day** (default): [DDD](#) | [DD](#) | [J](#)
- **First weekday** : [DAY](#) | [DY](#) | [D](#)
- **Hour** : [HH](#) | [HH12](#) | [HH24](#)
- **Minute** : [MI](#)
- **Second** : [SS](#)

#### Note

Hour, minute, and second rounding is not supported by [DATE](#) expressions.

### Examples

Round to the nearest hour:

```
=> SELECT TIMESTAMP_ROUND(CURRENT_TIMESTAMP, 'HH');
 ROUND

2016-04-28 15:00:00
(1 row)
```

Round to the nearest month:

```
=> SELECT TIMESTAMP_ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
 ROUND

2011-10-01 00:00:00
(1 row)
```

See also

[ROUND](#)

[TIMESTAMP\\_TRUNC](#)

Truncates the specified [TIMESTAMP](#). If you omit the precision argument, [TIMESTAMP\\_TRUNC](#) truncates to day ( [DD](#) ) precision.

Behavior type

- [Immutable](#) if the target date is a [TIMESTAMP](#)
- [Stable](#) if the target date is a [TIMESTAMPTZ](#)

Syntax

```
TIMESTAMP_TRUNC(trunc-target[, 'precision'])
```

Parameters

### trunc-target

An expression that evaluates to one of the following data types:

- [TIMESTAMP/TIMESTAMPTZ](#)
- [TIMESTAMPTZ](#)

## precision

A string constant that specifies precision for the truncated value, one of the following:

- **Century** : `CC` | `SCC`
- **Year** : `SYYY` | `YYYY` | `YEAR` | `YYY` | `YY` | `Y`
- **ISO Year** : `IYYY` | `IYY` | `IY` | `I`
- **Quarter** : `Q`
- **Month** : `MONTH` | `MON` | `MM` | `RM`
- **Same weekday as first day of year** : `WW`
- **Same weekday as first day of ISO year** : `IW`
- **Same weekday as first day of month** : `W`
- **Day** : `DDD` | `DD` | `J`
- **First weekday** : `DAY` | `DY` | `D`
- **Hour** : `HH` | `HH12` | `HH24`
- **Minute** : `MI`
- **Second** : `SS`

### Note

Hour, minute, and second truncating is not supported by `DATE` expressions.

## Examples

Truncate to the current hour:

```
=> SELECT TIMESTAMP_TRUNC(CURRENT_TIMESTAMP, 'HH');
TIMESTAMP_TRUNC

2016-04-29 08:00:00
(1 row)
```

Truncate to the month:

```
=> SELECT TIMESTAMP_TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
TIMESTAMP_TRUNC

2011-09-01 00:00:00
(1 row)
```

See also

[TRUNC](#)

[TIMESTAMPADD](#)

Adds the specified number of intervals to a `TIMESTAMP` or `TIMESTAMPTZ` value and returns a result of the same data type.

Behavior type

- [Immutable](#) if the input date is a `TIMESTAMP`
- [Stable](#) if the input date is a `TIMESTAMPTZ`

Syntax

```
TIMESTAMPADD (datepart, count, start-date);
```

Parameters

### *datepart*

Specifies the type of time intervals that `TIMESTAMPADD` adds to the specified start date. If *datepart* is an expression, it must be enclosed in parentheses:

```
TIMESTAMPADD(expression, interval, start;
```

*datepart* must evaluate to one of the following string literals, either quoted or unquoted:

- `year` | `yy` | `yyyy`
- `quarter` | `qq` | `q`
- `month` | `mm` | `m`
- `day` | `dayofyear` | `dd` | `d` | `dy` | `y`

- `week` | `wk` | `ww`
- `hour` | `hh`
- `minute` | `mi` | `n`
- `second` | `ss` | `s`
- `millisecond` | `ms`
- `microsecond` | `mcs` | `us`

### **count**

Integer or integer expression that specifies the number of *datepart* intervals to add to *start-date* .

### **start-date**

TIMESTAMP or TIMESTAMPTZ value.

### Examples

Add two months to the current date:

```
=> SELECT CURRENT_TIMESTAMP AS Today;
 Today

2016-05-02 06:56:57.923045-04
(1 row)

=> SELECT TIMESTAMPADD (MONTH, 2, (CURRENT_TIMESTAMP)) AS TodayPlusTwoMonths;;
 TodayPlusTwoMonths

2016-07-02 06:56:57.923045-04
(1 row)
```

Add 14 days to the beginning of the current month:

```
=> SELECT TIMESTAMPADD (DD, 14, (SELECT TRUNC((CURRENT_TIMESTAMP), 'MM')));
 timestampadd

2016-05-15 00:00:00
(1 row)
```

### TIMESTAMPDIFF

Returns the time span between two TIMESTAMP or TIMESTAMPTZ values, in the intervals specified. **TIMESTAMPDIFF** excludes the start date in its calculation.

### Behavior type

- [Immutable](#) if start and end dates are **TIMESTAMP**
- [Stable](#) if start and end dates are **TIMESTAMPTZ**

### Syntax

```
TIMESTAMPDIFF (datepart, start, end);
```

### Parameters

#### **datepart**

Specifies the type of date or time intervals that **TIMESTAMPDIFF** returns. If *datepart* is an expression, it must be enclosed in parentheses:

```
TIMESTAMPDIFF(expression, start, end);
```

*datepart* must evaluate to one of the following string literals, either quoted or unquoted:

- `year` | `yy` | `yyyy`
- `quarter` | `qq` | `q`
- `month` | `mm` | `m`
- `day` | `dayofyear` | `dd` | `d` | `dy` | `y`
- `week` | `wk` | `ww`
- `hour` | `hh`
- `minute` | `mi` | `n`
- `second` | `ss` | `s`

- [millisecond](#) | `ms`
- [microsecond](#) | `mcs` | `us`

### **start**, **end**

Specify the start and end dates, where *start* and *end* evaluate to one of the following data types:

- [TIMESTAMP/TIMESTAMPTZ](#)
- [TIMESTAMPTZ](#)

If *end* < *start*, [TIMESTAMPDIFF](#) returns a negative value.

### Date part intervals

[TIMESTAMPDIFF](#) uses the *datepart* argument to calculate the number of intervals between two dates, rather than the actual amount of time between them. For detailed information, see [DATEDIFF](#).

### Examples

```
=> SELECT TIMESTAMPDIFF (YEAR,'1-1-2006 12:34:00', '1-1-2008 12:34:00');
timestampdiff

 2
(1 row)
```

See also

[DATEDIFF](#)

### TRANSACTION\_TIMESTAMP

Returns a value of type `TIME WITH TIMEZONE` that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to [TRANSACTION\\_TIMESTAMP](#) within the same transaction return the same timestamp.

[TRANSACTION\\_TIMESTAMP](#) is equivalent to [CURRENT\\_TIMESTAMP](#), except it does not accept a precision parameter.

### Behavior type

[Stable](#)

### Syntax

```
TRANSACTION_TIMESTAMP()
```

### Examples

```
=> SELECT foo, bar FROM (SELECT TRANSACTION_TIMESTAMP() AS foo)foo, (SELECT TRANSACTION_TIMESTAMP() as bar)bar;
 foo | bar
-----+-----
2016-12-12 08:18:00.988528-05 | 2016-12-12 08:18:00.988528-05
(1 row)
```

See also

- [CLOCK\\_TIMESTAMP](#)
- [STATEMENT\\_TIMESTAMP](#)

### TRUNC

Truncates the specified date or time. If you omit the precision argument, [TRUNC](#) truncates to day ( `DD` ) precision.

### Behavior type

- [Immutable](#) if the target date is a [TIMESTAMP](#) or [DATE](#)
- [Stable](#) if the target date is a [TIMESTAMPTZ](#)

### Syntax

```
TRUNC(trunc-target[, 'precision'])
```

### Parameters

#### \* *trunc-target* \*

An expression that evaluates to one of the following data types:

- [DATE](#)

- [TIMESTAMP/TIMESTAMPZ](#)
- [TIMESTAMPZ](#)

### precision

A string constant that specifies precision for the truncated value, one of the following:

- **Century** : [CC](#) | [SCC](#)
- **Year** : [SYYY](#) | [YYYY](#) | [YEAR](#) | [YYY](#) | [YY](#) | [Y](#)
- **ISO Year** : [IYYY](#) | [IYY](#) | [IY](#) | [I](#)
- **Quarter** : [Q](#)
- **Month** : [MONTH](#) | [MON](#) | [MM](#) | [RM](#)
- **Same weekday as first day of year** : [WW](#)
- **Same weekday as first day of ISO year** : [IW](#)
- **Same weekday as first day of month** : [W](#)
- **Day** (default): [DDD](#) | [DD](#) | [J](#)
- **First weekday** : [DAY](#) | [DY](#) | [D](#)
- **Hour** : [HH](#) | [HH12](#) | [HH24](#)
- **Minute** : [MI](#)
- **Second** : [SS](#)

#### Note

Hour, minute, and second truncating is not supported by [DATE](#) expressions.

### Examples

Truncate to the current hour:

```
=> => SELECT TRUNC(CURRENT_TIMESTAMP, 'HH');
 TRUNC

2016-04-29 10:00:00
(1 row)
```

Truncate to the month:

```
=> SELECT TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
 TIMESTAMP_TRUNC

2011-09-01 00:00:00
(1 row)
```

See also

[TIMESTAMP\\_TRUNC](#)

WEEK

Returns the week of the year for the specified date as an integer, where the first week begins on the first Sunday on or preceding January 1.

Syntax

```
WEEK (date)
```

Behavior type

- [Immutable](#) if the specified date is a [TIMESTAMP](#), [DATE](#), or [VARCHAR](#)
- [Stable](#) if the specified date is a [TIMESTAMPZ](#)

Parameters

**date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPZ](#)

## Examples

January 2 is on Saturday, so **WEEK** returns 1:

```
=> SELECT WEEK ('1-2-2016'::DATE);
WEEK

 1
(1 row)
```

January 3 is the second Sunday in 2016, so **WEEK** returns 2:

```
=> SELECT WEEK ('1-3-2016'::DATE);
WEEK

 2
(1 row)
```

## WEEK\_ISO

Returns the week of the year for the specified date as an integer, where the first week starts on Monday and contains January 4. This function conforms with the ISO 8061 standard.

### Syntax

```
WEEK_ISO (date)
```

### Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP**, **DATE**, or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

### Parameters

#### **date**

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

## Examples

The first week of 2016 begins on Monday January 4:

```
=> SELECT WEEK_ISO ('1-4-2016'::DATE);
WEEK_ISO

 1
(1 row)
```

January 3 2016 returns week 53 of the previous year (2015):

```
=> SELECT WEEK_ISO ('1-3-2016'::DATE);
WEEK_ISO

 53
(1 row)
```

In 2015, January 4 is on Sunday, so the first week of 2015 begins on the preceding Monday (December 29 2014):

```
=> SELECT WEEK_ISO ('12-29-2014'::DATE);
WEEK_ISO

 1
(1 row)
```

## YEAR

Returns an integer that represents the year portion of the specified date.

### Syntax

```
YEAR(date)
```

### Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP** , **DATE** , **VARCHAR** , or **INTERVAL**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

### Parameters

#### ***date***

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)
  
- [INTERVAL](#)

### Examples

```
=> SELECT YEAR(CURRENT_DATE::DATE);
YEAR

2016
(1 row)
```

### See also

[YEAR\\_ISO](#)

YEAR\_ISO

Returns an integer that represents the year portion of the specified date. The return value is based on the ISO 8061 standard.

The first week of the ISO year is the week that contains January 4.

### Syntax

```
YEAR_ISO (date)
```

### Behavior type

- [Immutable](#) if the specified date is a **TIMESTAMP** , **DATE** , or **VARCHAR**
- [Stable](#) if the specified date is a **TIMESTAMPTZ**

### Parameters

#### ***date***

The date to process, one of the following data types:

- [VARCHAR](#)
- [DATE](#)
- [TIMESTAMP](#)
- [TIMESTAMPTZ](#)

### Examples

```
> SELECT YEAR_ISO(CURRENT_DATE::DATE);
YEAR_ISO

2016
(1 row)
```

### See also

[YEAR](#)

IP address functions

IP functions perform conversion, calculation, and manipulation operations on IP, network, and subnet addresses.

In this section

- [INET\\_ATON](#)
- [INET\\_NTOA](#)
- [V6\\_ATON](#)
- [V6\\_NTOA](#)
- [V6\\_SUBNETA](#)
- [V6\\_SUBNETN](#)
- [V6\\_TYPE](#)

## INET\_ATON

Converts a string that contains a dotted-quad representation of an IPv4 network address to an INTEGER. It trims any surrounding white space from the string. This function returns NULL if the string is NULL or contains anything other than a quad dotted IPv4 address.

Behavior type

[Immutable](#)

Syntax

```
INET_ATON (expression)
```

Arguments

***expression***

the string to convert.

Examples

```
=> SELECT INET_ATON('209.207.224.40');
inet_aton

3520061480
(1 row)

=> SELECT INET_ATON('1.2.3.4');
inet_aton

16909060
(1 row)

=> SELECT TO_HEX(INET_ATON('1.2.3.4'));
to_hex

1020304
(1 row)
```

See also

- [INET\\_NTOA](#)
- [V6\\_ATON](#)
- [V6\\_NTOA](#)
- [V6\\_SUBNETA](#)
- [V6\\_SUBNETN](#)
- [V6\\_TYPE](#)

## INET\_NTOA

Converts an INTEGER value into a VARCHAR dotted-quad representation of an IPv4 network address. INET\_NTOA returns NULL if the integer value is NULL, negative, or is greater than  $2^{32}$  (4294967295).

Behavior type

[Immutable](#)

Syntax

```
INET_NTOA (expression)
```

Arguments

***expression***

The integer network address to convert.

#### Examples

```
=> SELECT INET_NTOA(16909060);
inet_ntoa

1.2.3.4
(1 row)

=> SELECT INET_NTOA(03021962);
inet_ntoa

0.46.28.138
(1 row)
```

See also

- [INET\\_ATON](#)
- [V6\\_ATON](#)
- [V6\\_NTOA](#)
- [V6\\_SUBNETA](#)
- [V6\\_SUBNETN](#)
- [V6\\_TYPE](#)

#### V6\_ATON

Converts a string containing a colon-delimited IPv6 network address into a VARBINARY string. Any spaces around the IPv6 address are trimmed. This function returns NULL if the input value is NULL or it cannot be parsed as an IPv6 address. This function relies on the Linux function [inet\\_pton](#).

Behavior type

[Immutable](#)

Syntax

```
V6_ATON (expression)
```

Arguments

***expression***

(VARCHAR) the string containing an IPv6 address to convert.

#### Examples

```
=> SELECT V6_ATON('2001:DB8::8:800:200C:417A');
v6_aton

\001\015\270\000\000\000\000\000\000\010\010\000 \014Az
(1 row)

=> SELECT V6_ATON('1.2.3.4');
v6_aton

\000\000\000\000\000\000\000\000\000\000\000\000\377\377\001\002\003\004
(1 row)
SELECT TO_HEX(V6_ATON('2001:DB8::8:800:200C:417A'));
to_hex

20010db8000000000000080800200c417a
(1 row)

=> SELECT V6_ATON('::1.2.3.4');
v6_aton

\000\000\000\000\000\000\000\000\000\000\000\000\000\000\001\002\003\004
(1 row)
```

See also

- [V6\\_NTOA](#)
- [V6\\_SUBNETA](#)
- [V6\\_SUBNETN](#)
- [V6\\_TYPE](#)
- [INET\\_ATON](#)
- [INET\\_NTOA](#)

## V6\_NTOA

Converts an IPv6 address represented as varbinary to a character string.

Behavior type

[Immutable](#)

Syntax

```
V6_NTOA (expression)
```

Arguments

***expression***

( **VARBINARY** ) is the binary string to convert.

Notes

The following syntax converts an IPv6 address represented as **VARBINARY** B to a string A.

**V6\_NTOA** right-pads B to 16 bytes with zeros, if necessary, and calls the Linux function [inet\\_ntop](#).

```
=> V6_NTOA(VARBINARY B) -> VARCHAR A
```

If B is NULL or longer than 16 bytes, the result is NULL.

Vertica automatically converts the form '::ffff:1.2.3.4' to '1.2.3.4'.

Examples

```
=> SELECT V6_NTOA('\001\015\270\000\000\000\000\000\010\010\000 \014Az');
```

```
 v6_ntoa
```

```

2001:db8::8:800:200c:417a
```

```
(1 row)
```

```
=> SELECT V6_NTOA(V6_ATON('1.2.3.4'));
```

```
 v6_ntoa
```

```

1.2.3.4
```

```
(1 row)
```

```
=> SELECT V6_NTOA(V6_ATON('::1.2.3.4'));
```

```
 v6_ntoa
```

```

::1.2.3.4
```

```
(1 row)
```

See also

- [V6\\_ATON](#)

## V6\_SUBNETA

Returns a VARCHAR containing a subnet address in CIDR (Classless Inter-Domain Routing) format from a binary or alphanumeric IPv6 address. Returns NULL if either parameter is NULL, the address cannot be parsed as an IPv6 address, or the subnet value is outside the range of 0 to 128.

Behavior type

[Immutable](#)

Syntax

```
V6_SUBNETA (address, subnet)
```

## Arguments

### **address**

VARBINARY or VARCHAR containing the IPv6 address.

### **subnet**

The size of the subnet in bits as an INTEGER. This value must be greater than zero and less than or equal to 128.

## Examples

```
=> SELECT V6_SUBNETA(V6_ATON('2001:db8::8:800:200c:417a'), 28);
v6_subneta

2001:db0::/28
(1 row)
```

## See also

- [V6\\_ATON](#)
- [V6\\_NTOA](#)
- [V6\\_SUBNETN](#)
- [V6\\_TYPE](#)
- [INET\\_ATON](#)
- [INET\\_NTOA](#)

## V6\_SUBNETN

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a varbinary or alphanumeric IPv6 address.

## Behavior type

[Immutable](#)

## Syntax

```
V6_SUBNETN (address, subnet-size)
```

## Arguments

### **address**

The IPv6 address as a VARBINARY or VARCHAR. The format you pass in determines the data type of the output. If you pass in a VARBINARY address, V6\_SUBNETN returns a VARBINARY value. If you pass in a VARCHAR value, it returns a VARCHAR.

### **subnet-size**

The size of the subnet as an INTEGER.

## Notes

The following syntax masks a BINARY IPv6 address **B** so that the **N** left-most bits of **S** form a subnet address, while the remaining right-most bits are cleared.

**V6\_SUBNETN** right-pads **B** to 16 bytes with zeros, if necessary and masks **B**, preserving its **N**-bit subnet prefix.

```
=> V6_SUBNETN(VARBINARY B, INT8 N) -> VARBINARY(16) S
```

If **B** is NULL or longer than 16 bytes, or if **N** is not between 0 and 128 inclusive, the result is NULL.

**S** = **[B]/N** in [Classless Inter-Domain Routing](#) notation (CIDR notation).

The following syntax masks an alphanumeric IPv6 address **A** so that the **N** leftmost bits form a subnet address, while the remaining rightmost bits are cleared.

```
=> V6_SUBNETN(VARCHAR A, INT8 N) -> V6_SUBNETN(V6_ATON(A), N) -> VARBINARY(16) S
```

## Examples

This example returns VARBINARY, after using V6\_ATON to convert the VARCHAR string to VARBINARY:

```
=> SELECT V6_SUBNETN(V6_ATON('2001:db8::8:800:200c:417a'), 28);
v6_subnetn

\001\015\260\000\000\000\000\000\000\000\000\000\000\000\000\000\000
```

## See also

- [V6\\_NTOA](#)
- [V6\\_TYPE](#)
- [V6\\_SUBNETA](#)
- [INET\\_ATON](#)
- [INET\\_NTOA](#)

## V6\_TYPE

Returns an INTEGER value that classifies the type of the network address passed to it as defined in [IETF RFC 4291 section 2.4](#). For example, If you pass this function the string **127.0.0.1** , it returns 2 which indicates the address is a loopback address. This function accepts both IPv4 and IPv6 addresses.

Behavior type

[Immutable](#)

Syntax

```
V6_TYPE (address)
```

Arguments

**address**

A VARBINARY or VARCHAR containing an IPv6 or IPv4 address to describe.

Returns

The values returned by this function are:

Return Value	Address Type	Description
0	GLOBAL	Global unicast addresses
1	LINKLOCAL	Link-Local unicast (and private-use) addresses
2	LOOPBACK	Loopback addresses
3	UNSPECIFIED	Unspecifiedaddresses
4	MULTICAST	Multicastaddresses

The return value is based on the following table of IP address ranges:

Address Family	CIDR	Type
IPv4	0.0.0.0/8	UNSPECIFIED
	10.0.0.0/8	LINKLOCAL
	127.0.0.0/8	LOOPBACK
	169.254.0.0/16	LINKLOCAL
	172.16.0.0/12	LINKLOCAL
	192.168.0.0/16	LINKLOCAL
	224.0.0.0/4	MULTICAST
	All other addresses	GLOBAL
IPv6	::0/128	UNSPECIFIED
	::1/128	LOOPBACK

	fe80::/10	LINKLOCAL
	ff00::/8	MULTICAST
	All other addresses	GLOBAL

This function returns NULL if you pass it a NULL value or an invalid address.

#### Examples

```
=> SELECT V6_TYPE(V6_ATON('192.168.2.10'));
v6_type

 1
(1 row)

=> SELECT V6_TYPE(V6_ATON('2001:db8::8:800:200c:417a'));
v6_type

 0
(1 row)
```

#### See also

- [V6\\_ATON](#)
- [V6\\_NTOA](#)
- [INET\\_ATON](#)
- [INET\\_NTOA](#)
- [V6\\_SUBNETN](#)

- [IP Version 6 Addressing Architecture](#)
- [IPv4 Global Unicast Address Assignments](#)

#### Sequence functions

The sequence functions provide simple, multiuser-safe methods for obtaining successive sequence values from sequence objects.

#### In this section

- [CURRVAL](#)
- [NEXTVAL](#)

#### CURRVAL

Returns the last value across all nodes that was set by [NEXTVAL](#) on this sequence in the current session. If NEXTVAL was never called on this sequence since its creation, Vertica returns an error.

#### Syntax

```
CURRVAL ('[[database.]schema.]sequence-name')
```

#### Parameters

**[ *database* .] *schema***

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

***sequence-name***

The target sequence

#### Privileges

- SELECT privilege on sequence
- USAGE privilege on sequence schema

#### Restrictions

You cannot invoke CURRVAL in a SELECT statement, in the following contexts:

- WHERE clause

- GROUP BY clause
- ORDER BY clause
- DISTINCT clause
- UNION
- Subquery

You also cannot invoke CURRVAL to act on a sequence in:

- UPDATE or DELETE subqueries
- Views

Examples

See [Creating and using named sequences](#).

See also

[NEXTVAL](#)

NEXTVAL

Returns the next value in a sequence. Call NEXTVAL after creating a sequence to initialize the sequence with its default value. Thereafter, call NEXTVAL to increment the sequence value for ascending sequences, or decrement its value for descending sequences.

Syntax

```
NEXTVAL ('[[database.]schema.]sequence')
```

Parameters

[ **database** .] **schema**

Database and [schema](#). The default schema is **public**. If you specify a database, it must be the current database.

**sequence**

Identifies the target sequence.

Privileges

- SELECT privilege on sequence
- USAGE privilege on sequence schema

Restrictions

You cannot invoke NEXTVAL in a SELECT statement, in the following contexts:

- WHERE clause
- GROUP BY clause
- ORDER BY clause
- DISTINCT clause
- UNION
- Subquery

You also cannot invoke NEXTVAL to act on a sequence in:

- UPDATE or DELETE subqueries
- Views

You can use subqueries to work around some of these restrictions. For example, to use sequences with a DISTINCT clause:

```
=> SELECT t.col1, shift_allocation_seq.NEXTVAL FROM (
 SELECT DISTINCT col1 FROM av_temp1) t;
```

Examples

See [Creating and using named sequences](#).

See also

[CURRVAL](#)

String functions

String functions perform conversion, extraction, or manipulation operations on strings, or return information about strings.

This section describes functions and operators for examining and manipulating string values. Strings in this context include values of the types CHAR, VARCHAR, BINARY, and VARBINARY.

Unless otherwise noted, all of the functions listed in this section work on all four data types. As opposed to some other SQL implementations, Vertica keeps CHAR strings unpadded internally, padding them only on final output. So converting a CHAR(3) 'ab' to VARCHAR(5) results in a VARCHAR of length 2, not one with length 3 including a trailing space.

Some of the functions described here also work on data of non-string types by converting that data to a string representation first. Some functions work only on character strings, while others work only on binary strings. Many work for both. BINARY and VARBINARY functions ignore multibyte UTF-8 character boundaries.

Non-binary character string functions handle normalized multibyte UTF-8 characters, as specified by the Unicode Consortium. Unless otherwise specified, those character string functions for which it matters can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of UTF-8 characters. This is accomplished by adding "USING OCTETS" or "USING CHARACTERS" (default) as a parameter to the function.

Some character string functions are [stable](#) because in general UTF-8 case-conversion, searching and sorting can be locale dependent. Thus, LOWER is stable, while LOWERB is [immutable](#). The USING OCTETS clause converts these functions into their "B" forms, so they become immutable. If the locale is set to collation=binary, which is the default, all string functions—except CHAR\_LENGTH/CHARACTER\_LENGTH, LENGTH, SUBSTR, and OVERLAY—are converted to their "B" forms and so are immutable.

BINARY implicitly converts to VARBINARY, so functions that take VARBINARY arguments work with BINARY.

For other functions that operate on strings (but not VARBINARY), see [Regular expression functions](#).

## ASCII

Converts the first character of a VARCHAR datatype to an INTEGER. This function is the opposite of the [CHR](#) function.

ASCII operates on UTF-8 characters and single-byte ASCII characters. It returns the same results for the ASCII subset of UTF-8.

Behavior type

[Immutable](#)

Syntax

```
ASCII (expression)
```

Arguments

***expression***

VARCHAR (string) to convert.

Examples

This example returns employee last names that begin with L. The ASCII equivalent of L is 76:

```
=> SELECT employee_last_name FROM employee_dimension
 WHERE ASCII(SUBSTR(employee_last_name, 1, 1)) = 76
 LIMIT 5;
employee_last_name

Lewis
Lewis
Lampert
Lampert
Li
(5 rows)
```

## BIT\_LENGTH

Returns the length of the string expression in bits (bytes \* 8) as an INTEGER. BIT\_LENGTH applies to the contents of VARCHAR and VARBINARY fields.

Behavior type

[Immutable](#)

## Syntax

```
BIT_LENGTH (expression)
```

## Arguments

### ***expression***

(CHAR or VARCHAR or BINARY or VARBINARY) is the string to convert.

## Examples

Expression	Result
SELECT BIT_LENGTH('abc'::varbinary);	24
SELECT BIT_LENGTH('abc'::binary);	8
SELECT BIT_LENGTH(''::varbinary);	0
SELECT BIT_LENGTH(''::binary);	8
SELECT BIT_LENGTH(null::varbinary);	
SELECT BIT_LENGTH(null::binary);	
SELECT BIT_LENGTH(VARCHAR 'abc');	24
SELECT BIT_LENGTH(CHAR 'abc');	24
SELECT BIT_LENGTH(CHAR(6) 'abc');	48
SELECT BIT_LENGTH(VARCHAR(6) 'abc');	24
SELECT BIT_LENGTH(BINARY(6) 'abc');	48
SELECT BIT_LENGTH(BINARY 'abc');	24
SELECT BIT_LENGTH(VARBINARY 'abc');	24
SELECT BIT_LENGTH(VARBINARY(6) 'abc');	24

## See also

- [CHARACTER\\_LENGTH](#)
- [LENGTH](#)
- [OCTET\\_LENGTH](#)

## BITCOUNT

Returns the number of one-bits (sometimes referred to as set-bits) in the given VARBINARY value. This is also referred to as the population count.

## Behavior type

[Immutable](#)

## Syntax

```
BITCOUNT (expression)
```

## Arguments

### ***expression***

(BINARY or VARBINARY) is the string to return.

## Examples

```
=> SELECT BITCOUNT(HEX_TO_BINARY('0x10'));
BITCOUNT

 1
(1 row)
=> SELECT BITCOUNT(HEX_TO_BINARY('0xF0'));
BITCOUNT

 4
(1 row)
=> SELECT BITCOUNT(HEX_TO_BINARY('0xAB'));
BITCOUNT

 5
(1 row)
```

## BITSTRING\_TO\_BINARY

Translates the given VARCHAR bitstring representation into a VARBINARY value. This function is the inverse of [TO\\_BITSTRING](#).

Behavior type

[Immutable](#)

Syntax

```
BITSTRING_TO_BINARY (expression)
```

Arguments

***expression***

The VARCHAR string to process.

Examples

If there are an odd number of characters in the hex value, the first character is treated as the low nibble of the first (furthest to the left) byte.

```
=> SELECT BITSTRING_TO_BINARY('0110000101100010');
BITSTRING_TO_BINARY

ab
(1 row)
```

## BTRIM

Removes the longest string consisting only of specified characters from the start and end of a string.

Behavior type

[Immutable](#)

Syntax

```
BTRIM (expression [, characters-to-remove])
```

Arguments

***expression***

(CHAR or VARCHAR) is the string to modify

***characters-to-remove***

(CHAR or VARCHAR) specifies the characters to remove. The default is the space character.

Examples

```
=> SELECT BTRIM('xyxtrimyyx', 'xy');
BTRIM

trim
(1 row)
```

See also

- [LTRIM](#)

- [RTRIM](#)
- [TRIM](#)

## CHARACTER\_LENGTH

The CHARACTER\_LENGTH() function:

- Returns the string length in UTF-8 characters for CHAR and VARCHAR columns
- Returns the string length in bytes (octets) for BINARY and VARBINARY columns
- Strips the padding from CHAR expressions but not from VARCHAR expressions
- Is identical to [LENGTH\(\)](#) for CHAR and VARCHAR. For binary types, CHARACTER\_LENGTH() is identical to [OCTET\\_LENGTH\(\)](#).

Behavior type

[Immutable](#) if **USING OCTETS**, [stable](#) otherwise.

Syntax

```
[CHAR_LENGTH | CHARACTER_LENGTH] (expression ... [USING { CHARACTERS | OCTETS }])
```

Arguments

### **expression**

(CHAR or VARCHAR) is the string to measure

### **USING CHARACTERS | OCTETS**

Determines whether the character length is expressed in characters (the default) or octets.

Examples

```
=> SELECT CHAR_LENGTH('1234 '::CHAR(10) USING OCTETS);
```

```
octet_length
```

```

 4
```

```
(1 row)
```

```
=> SELECT CHAR_LENGTH('1234 '::VARCHAR(10));
```

```
char_length
```

```

 6
```

```
(1 row)
```

```
=> SELECT CHAR_LENGTH(NULL::CHAR(10)) IS NULL;
```

```
?column?
```

```

t
```

```
(1 row)
```

See also

- [BIT\\_LENGTH](#)

## CHR

Converts the first character of an INTEGER datatype to a VARCHAR.

Behavior type

[Immutable](#)

Syntax

```
CHR (expression)
```

Arguments

### **expression**

(INTEGER) is the string to convert and is masked to a single character.

Notes

- CHR is the opposite of the [ASCII](#) function.
- CHR operates on UTF-8 characters, not only on single-byte ASCII characters. It continues to get the same results for the ASCII subset of UTF-8.

## Examples

This example returns the VARCHAR datatype of the CHR expressions 65 and 97 from the employee table:

```
=> SELECT CHR(65), CHR(97) FROM employee;
```

```
CHR | CHR
```

```
-----+-----
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
A | a
```

```
(12 rows)
```

## COLLATION

Applies a collation to two or more strings. Use **COLLATION** with **ORDER BY** , **GROUP BY** , and equality clauses.

### Syntax

```
COLLATION ('expression' [, 'locale_or_collation_name'])
```

### Arguments

#### ' **expression** '

Any expression that evaluates to a column name or to two or more values of type **CHAR** or **VARCHAR** .

#### ' **locale\_or\_collation\_name** '

The [ICU \(International Components for Unicode\)](#) locale or collation name to use when collating the string. If you omit this parameter, **COLLATION** uses the collation associated with the session locale.

To determine the current session locale, enter the vsqll meta-command **\locale** :

```
=> \locale
```

```
en_US@collation=binary
```

To set the locale and collation, use **\locale** as follows:

```
=> \locale en_US@collation=binary
```

```
INFO 2567: Canonical locale: 'en_US'
```

```
Standard collation: 'LEN_KBINARY'
```

```
English (United States)
```

## Locales

The locale used for **COLLATION** can be one of the following:

- The default locale
- A session locale
- A locale that you specify when you call **COLLATION** . If you specify the locale, Vertica applies the collation associated with that locale to the data. **COLLATION** does not modify the collation for any other columns in the table.

For a list of valid ICU locales, go to [Locale Explorer \(ICU\)](#) .

## Binary and non-binary collations

The Vertica default locale is **en\_US@collation=binary** , which uses **binary collation** . Binary collation compares binary representations of strings. Binary collation is fast, but it can result in a sort order where **K** precedes **c** because the binary representation of **K** is lower than **c** .

For non-binary collation, Vertica transforms the data according to the rules of the locale or the specified collation, and then applies the sorting rules. Suppose the locale collation is non-binary and you request a GROUP BY on string data. In this case, Vertica calls **COLLATION**, whether or not you specify the function in your query.

For information about collation naming, see [Collator Naming Scheme](#).

## Examples

### Collating GROUP BY results

The following examples are based on a **Premium\_Customer** table that contains the following data:

```
=> SELECT * FROM Premium_Customer;
```

ID	LName	FName
1	Mc Coy	Bob
2	Mc Coy	Janice
3	McCoy	Jody
4	McCoy	Peter
5	McCoy	Brendon
6	Mccoy	Cameron
7	Mccoy	Lisa

The first statement shows how **COLLATION** applies the collation for the **EN\_US** locale to the **LName** column for the locale **EN\_US**. Vertica sorts the **GROUP BY** output as follows:

- Last names with spaces
- Last names where "coy" starts with a lowercase letter
- Last names where "Coy" starts with an uppercase letter

```
=> SELECT * FROM Premium_Customer ORDER BY COLLATION(LName, 'EN_US'), FName;
```

ID	LName	FName
1	Mc Coy	Bob
2	Mc Coy	Janice
6	Mccoy	Cameron
7	Mccoy	Lisa
5	McCoy	Brendon
3	McCoy	Jody
4	McCoy	Peter

The next statement shows how **COLLATION** collates the **LName** column for the locale **LEN\_AS**:

- **LEN** indicates the language (L) is English (**EN**).
- **AS** (Alternate Shifted) instructs **COLLATION** that lowercase letters come before uppercase (shifted) letters.

In the results, the last names in which "coy" starts with a lowercase letter precede the last names where "Coy" starts with an uppercase letter.

```
=> SELECT * FROM Premium_Customer ORDER BY COLLATION(LName, 'LEN_AS'), FName;
```

ID	LName	FName
6	Mccoy	Cameron
7	Mccoy	Lisa
1	Mc Coy	Bob
5	McCoy	Brendon
2	Mc Coy	Janice
3	McCoy	Jody
4	McCoy	Peter

### Comparing strings with an equality clause

In the following query, **COLLATION** removes spaces and punctuation when comparing two strings in English. It then determines whether the two strings still have the same value after the punctuation has been removed:

```
=> SELECT COLLATION ('U.S.A', 'LEN_AS') = COLLATION('USA', 'LEN_AS');
?column?

t
```

Sorting strings in non-english languages

The following table contains data that uses the German character eszett, ß:

```
=> SELECT * FROM t1;
 a | b | c
-----+-----
ßstringß | 1 | 10
SSstringSS | 2 | 20
random1 | 3 | 30
random1 | 4 | 40
random2 | 5 | 50
```

When you specify the collation `LDE_S1` :

- `LDE` indicates the language ( `L` ) is German ( `DE` ).
- `S1` indicates the strength ( `S` ) of 1 (primary). This value indicates that the collation does not need to consider accents and case.

The query returns the data in the following order:

```
=> SELECT a FROM t1 ORDER BY COLLATION(a, 'LDE_S1');
 a

random1
random1
random2
SSstringSS
ßstringß
```

## CONCAT

Concatenates two strings and returns a varchar data type. If either argument is null, concat returns null.

Syntax

```
CONCAT ('string-expression1', string-expression2)
```

Behavior type

[Immutable](#)

Arguments

***string-expression1*** , ***string-expression2***

The values to concatenate, any data type that can be cast to a string value.

Examples

The following examples use a sample table named `alphabet` with two varchar columns:

```
=> CREATE TABLE alphabet (letter1 varchar(2), letter2 varchar(2));
CREATE TABLE
=> COPY alphabet FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A|B
>> C|D
>> \.
=> SELECT * FROM alphabet;
letter1 | letter2
-----+-----
C | D
A | B
(2 rows)
```

Concatenate the contents of the first column with a character string:

```
=> SELECT CONCAT(letter1, ' is a letter') FROM alphabet;
 CONCAT

A is a letter
C is a letter
(2 rows)
```

Concatenate the output of two nested CONCAT functions:

```
=> SELECT CONCAT(CONCAT(letter1, ' and '), CONCAT(letter2, ' are both letters')) FROM alphabet;
 CONCAT

C and D are both letters
A and B are both letters
(2 rows)
```

Concatenate a date and string:

```
=> SELECT current_date today;
 today

2021-12-10
(1 row)

=> SELECT CONCAT('2021-12-31'::date - current_date, ' days until end of year 2021');
 CONCAT

21 days until end of year 2021
(1 row)
```

## DECODE

Compares \* **expression** \* to each search value one by one. If \* **expression** \* is equal to a search, the function returns the corresponding result. If no match is found, the function returns default. If default is omitted, the function returns null.

DECODE is similar to the IF-THEN-ELSE and [CASE](#) expressions:

```
CASE expression
[WHEN search THEN result]
[WHEN search THEN result]
...
[ELSE default];
```

The arguments can have any data type supported by Vertica. The result types of individual results are promoted to the least common type that can be used to represent all of them. This leads to a character string type, an exact numeric type, an approximate numeric type, or a DATETIME type, where all the various result arguments must be of the same type grouping.

Behavior type

[Immutable](#)

Syntax

```
DECODE (expression, search, result [, search, result]...[, default])
```

Arguments

### **expression**

The value to compare.

### **search**

The value compared against *expression*.

### **result**

The value returned, if \* **expression** \* is equal to search.

### **default**

Optional. If no matches are found, DECODE returns default. If default is omitted, then DECODE returns NULL (if no matches are found).

## Examples

The following example converts numeric values in the weight column from the product\_dimension table to descriptive values in the output.

```
=> SELECT product_description, DECODE(weight,
 2, 'Light',
 50, 'Medium',
 71, 'Heavy',
 99, 'Call for help',
 'N/A')
FROM product_dimension
WHERE category_description = 'Food'
AND department_description = 'Canned Goods'
AND sku_number BETWEEN 'SKU-#49750' AND 'SKU-#49999'
LIMIT 15;
product_description | case
-----+-----
Brand #499 canned corn | N/A
Brand #49900 fruit cocktail | Medium
Brand #49837 canned tomatoes | Heavy
Brand #49782 canned peaches | N/A
Brand #49805 chicken noodle soup | N/A
Brand #49944 canned chicken broth | N/A
Brand #49819 canned chili | N/A
Brand #49848 baked beans | N/A
Brand #49989 minestrone soup | N/A
Brand #49778 canned peaches | N/A
Brand #49770 canned peaches | N/A
Brand #4977 fruit cocktail | N/A
Brand #49933 canned olives | N/A
Brand #49750 canned olives | Call for help
Brand #49777 canned tomatoes | N/A
(15 rows)
```

## EDIT\_DISTANCE

Calculates and returns the [Levenshtein distance](#) between two strings. The return value indicates the minimum number of single-character edits—insertions, deletions, or substitutions—that are required to change one string into the other. Compare to [Jaro distance](#) and [Jaro-Winkler distance](#).

### Behavior type

[Immutable](#)

### Syntax

```
EDIT_DISTANCE (string-expression1, string-expression2)
```

### Arguments

***string-expression1*** , ***string-expression2***

The two VARCHAR expressions to compare.

### Examples

The Levenshtein distance between **kitten** and **knitting** is 3:

```
=> SELECT EDIT_DISTANCE ('kitten', 'knitting');
EDIT_DISTANCE

3
(1 row)
```

EDIT\_DISTANCE calculates that no fewer than three changes are required to transform **kitten** to **knitting** :

1. **kitten** → **knitten** (insert **n** after **k**)
2. **knitten** → **knittin** (substitute **i** for **e**)

### 3. knittin → knitting (append g)

#### GREATEST

Returns the largest value in a list of expressions of any data type. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Stable](#)

Syntax

```
GREATEST ({ * | expression[,...] })
```

Arguments

\* | *expression* [...]

The expressions to evaluate, one of the following:

- \* (asterisk)  
Evaluates all columns in the queried table.
- *expression*  
An expression of any data type. Functions that are included in *expression* must be deterministic.

Examples

GREATEST returns 10 as the largest value in the list:

```
=> SELECT GREATEST(7,5,10);
GREATEST

 10
(1 row)
```

If you put quotes around the integer expressions, GREATEST compares the values as strings and returns '7' as the greatest value:

```
=> SELECT GREATEST('7', '5', '10');
GREATEST

 7
(1 row)
```

The next example returns FLOAT 1.5 as the greatest because the integer is implicitly cast to float:

```
=> SELECT GREATEST(1, 1.5);
GREATEST

 1.5
(1 row)
```

GREATEST queries all columns in a view based on the VMart table [product\\_dimension](#), and returns the largest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
```

```
CREATE VIEW
```

```
=> SELECT shelf_width, shelf_height, shelf_depth, greatest(*) FROM query1 WHERE shelf_width = 1;
shelf_width | shelf_height | shelf_depth | greatest
```

```
-----+-----+-----+-----
1 | 3 | 1 | 3
1 | 3 | 3 | 3
1 | 5 | 4 | 5
1 | 2 | 2 | 2
1 | 1 | 3 | 3
1 | 2 | 2 | 2
1 | 2 | 3 | 3
1 | 1 | 5 | 5
1 | 1 | 4 | 4
1 | 5 | 3 | 5
1 | 4 | 2 | 4
1 | 4 | 5 | 5
1 | 5 | 3 | 5
1 | 2 | 5 | 5
1 | 4 | 2 | 4
1 | 4 | 4 | 4
1 | 1 | 2 | 2
1 | 4 | 3 | 4
...
```

See also

[LEAST](#)

[GREATESTB](#)

Returns the largest value in a list of expressions of any data type, using binary ordering. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Immutable](#)

Syntax

```
GREATEST ({ * | expression[...] })
```

Arguments

\* | ***expression*** [...]

The expressions to evaluate, one of the following:

- \* (asterisk)  
Evaluates all columns in the queried table.
- *expression*  
An expression of any data type. Functions that are included in *expression* must be deterministic.

Examples

The following command selects *straße* as the greatest in the series of inputs:

```
=> SELECT GREATESTB('straße', 'strasse');
```

```
GREATESTB
```

```

straße
(1 row)
```

GREATESTB returns 10 as the largest value in the list:

```
=> SELECT GREATESTB(7,5,10);
```

```
GREATESTB
```

```

10
(1 row)
```

If you put quotes around the integer expressions, GREATESTB compares the values as strings and returns '7' as the greatest value:

```
=> SELECT GREATESTB('7', '5', '10');
GREATESTB

7
(1 row)
```

The next example returns FLOAT 1.5 as the greatest because the integer is implicitly cast to float:

```
=> SELECT GREATESTB(1, 1.5);
GREATESTB

1.5
(1 row)
```

GREATESTB queries all columns in a view based on the VMart table `product_dimension`, and returns the largest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
CREATE VIEW
=> SELECT shelf_width, shelf_height, shelf_depth, greatestb(*) FROM query1 WHERE shelf_width = 1;
shelf_width | shelf_height | shelf_depth | greatestb
-----+-----+-----+-----
1 | 3 | 1 | 3
1 | 3 | 3 | 3
1 | 5 | 4 | 5
1 | 2 | 2 | 2
1 | 1 | 3 | 3
1 | 2 | 2 | 2
1 | 2 | 3 | 3
1 | 1 | 5 | 5
1 | 1 | 4 | 4
1 | 5 | 3 | 5
1 | 4 | 2 | 4
1 | 4 | 5 | 5
1 | 5 | 3 | 5
1 | 2 | 5 | 5
1 | 4 | 2 | 4
...
```

See also

[LEASTB](#)

[HEX\\_TO\\_BINARY](#)

Translates the given VARCHAR hexadecimal representation into a VARBINARY value.

Behavior type

[Immutable](#)

Syntax

```
HEX_TO_BINARY ([0x] expression)
```

Arguments

**expression**

(BINARY or VARBINARY) String to translate.

**0x**

Optional prefix.

Notes

VARBINARY HEX\_TO\_BINARY(VARCHAR) converts data from character type in hexadecimal format to binary type. This function is the inverse of [TO\\_HEX](#).

```
HEX_TO_BINARY(TO_HEX(x)) = x
```

```
TO_HEX(HEX_TO_BINARY(x)) = x
```

If there are an odd number of characters in the hexadecimal value, the first character is treated as the low nibble of the first (furthest to the left) byte.

## Examples

If the given string begins with "0x" the prefix is ignored. For example:

```
=> SELECT HEX_TO_BINARY('0x6162') AS hex1, HEX_TO_BINARY('6162') AS hex2;
hex1 | hex2
-----+-----
ab | ab
(1 row)
```

If an invalid hex value is given, Vertica returns an "invalid binary representation" error; for example:

```
=> SELECT HEX_TO_BINARY('0xffgf');
ERROR: invalid hex string "0xffgf"
```

See also

- [TO\\_HEX](#)

## HEX\_TO\_INTEGER

Translates the given VARCHAR hexadecimal representation into an INTEGER value.

Vertica completes this conversion as follows:

- Adds the 0x prefix if it is not specified in the input
- Casts the VARCHAR string to a NUMERIC
- Casts the NUMERIC to an INTEGER

Behavior type

[Immutable](#)

Syntax

```
HEX_TO_INTEGER ([0x] expression)
```

Arguments

### ***expression***

VARCHAR is the string to translate.

### **0x**

Is the optional prefix.

## Examples

You can enter the string with or without the 0x prefix. For example:

```
=> SELECT HEX_TO_INTEGER ('0aedc')
 AS hex1,HEX_TO_INTEGER ('aedc') AS hex2;
hex1 | hex2
-----+-----
44764 | 44764
(1 row)
```

If you pass the function an invalid hex value, Vertica returns an [invalid input syntax](#) error; for example:

```
=> SELECT HEX_TO_INTEGER ('0xffgf');
ERROR 3691: Invalid input syntax for numeric: "0xffgf"
```

See also

- [TO\\_HEX](#)
- [HEX\\_TO\\_BINARY](#)

## INITCAP

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.

Behavior type

[Immutable](#)

Syntax

INITCAP ( *expression* )

Arguments

***expression***

(VARCHAR) is the string to format.

Notes

- Depends on collation setting of the locale.
- INITCAP is restricted to 32750 octet inputs, since it is possible for the UTF-8 representation of result to double in size.

Examples

Expression	Result
SELECT INITCAP('high speed database');	High Speed Database
SELECT INITCAP('LINUX TUTORIAL');	Linux Tutorial
SELECT INITCAP('abc DEF 123aVC 124Btd,IAsT');	Abc Def 123Avc 124Btd,Last
SELECT INITCAP('');	
SELECT INITCAP(null);	

INITCAPB

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase. Multibyte characters are not converted and are skipped.

Behavior type

[Immutable](#)

Syntax

INITCAPB ( *expression* )

Arguments

***expression***

(VARCHAR) is the string to format.

Notes

Depends on collation setting of the locale.

Examples

Expression	Result
SELECT INITCAPB('étudiant');	éTudiant
SELECT INITCAPB('high speed database');	High Speed Database
SELECT INITCAPB('LINUX TUTORIAL');	Linux Tutorial
SELECT INITCAPB('abc DEF 123aVC 124Btd,IAsT');	Abc Def 123Avc 124Btd,Last
SELECT INITCAPB('');	
SELECT INITCAPB(null);	

INSERT

Inserts a character string into a specified location in another character string.

Syntax

```
INSERT('string1', n, m, 'string2')
```

Behavior type

[Immutable](#)

Arguments

**string1**

(VARCHAR) Is the string in which to insert the new string.

**n**

A character of type INTEGER that represents the starting point for the insertion within\* **string1** \*. You specify the number of characters from the first character in string1 as the starting point for the insertion. For example, to insert characters before "c", in the string "abcdef," enter 3.

**m**

A character of type INTEGER that represents the number of characters in\* **string1** (if any) \*that should be replaced by the insertion. For example,if you want the insertion to replace the letters "cd" in the string "abcdef, " enter 2.

**string2**

(VARCHAR) Is the string to be inserted.

Examples

The following example changes the string Warehouse to Storehouse using the INSERT function:

```
=> SELECT INSERT ('Warehouse',1,3,'Stor');
INSERT

Storehouse
(1 row)
```

INSTR

Searches \* **string** \*for \* **substring** \*and returns an integer indicating the position of the character in \* **string** \*that is the first character of this **occurrence** . The return value is based on the character position of the identified character.

Behavior type

[Immutable](#)

Syntax

```
INSTR (string , substring [, position [, occurrence]])
```

Arguments

**string**

(CHAR or VARCHAR, or BINARY or VARBINARY) Text expression to search.

**substring**

(CHAR or VARCHAR, or BINARY or VARBINARY) String to search for.

**position**

Nonzero integer indicating the character of string where Vertica begins the search. If position is negative, then Vertica counts backward from the end of string and then searches backward from the resulting position. The first character of string occupies the default position 1, and position cannot be 0.

**occurrence**

Integer indicating which occurrence of string Vertica searches. The value of occurrence must be positive (greater than 0), and the default is 1.

Notes

Both **position** and **occurrence** must be of types that can resolve to an integer. The default values of both parameters are 1, meaning Vertica begins searching at the first character of string for the first occurrence of substring. The return value is relative to the beginning of string, regardless of the value of position, and is expressed in characters.

If the search is unsuccessful (that is, if substring does not appear \* **occurrence** \*times after the **position** character of **string**, the return value is 0.

Examples

The first example searches forward in string 'abc' for substring 'b'. The search returns the position in 'abc' where 'b' occurs, or position 2. Because no position parameters are given, the default search starts at 'a', position 1.

```
=> SELECT INSTR('abc', 'b');
INSTR

 2
(1 row)
```

The following three examples use character position to search backward to find the position of a substring.

#### Note

Although it might seem intuitive that the function returns a negative integer, the position of *n* occurrence is read left to right in the string, even though the search happens in reverse (from the end—or right side—of the string).

In the first example, the function counts backward one character from the end of the string, starting with character 'c'. The function then searches backward for the first occurrence of 'a', which it finds it in the first position in the search string.

```
=> SELECT INSTR('abc', 'a', -1);
INSTR

 1
(1 row)
```

In the second example, the function counts backward one byte from the end of the string, starting with character 'c'. The function then searches backward for the first occurrence of 'a', which it finds it in the first position in the search string.

```
=> SELECT INSTR(VARBINARY 'abc', VARBINARY 'a', -1);
INSTR

 1
(1 row)
```

In the third example, the function counts backward one character from the end of the string, starting with character 'b', and searches backward for substring 'bc', which it finds in the second position of the search string.

```
=> SELECT INSTR('abcb', 'bc', -1);
INSTR

 2
(1 row)
```

In the fourth example, the function counts backward one character from the end of the string, starting with character 'b', and searches backward for substring 'bcef', which it does not find. The result is 0.

```
=> SELECT INSTR('abcb', 'bcef', -1);
INSTR

 0
(1 row)
```

In the fifth example, the function counts backward one byte from the end of the string, starting with character 'b', and searches backward for substring 'bcef', which it does not find. The result is 0.

```
=> SELECT INSTR(VARBINARY 'abcb', VARBINARY 'bcef', -1);
INSTR

 0
(1 row)
```

Multibyte characters are treated as a single character:

```
=> SELECT INSTR('aébc', 'b');
INSTR

3
(1 row)
```

Use INSTRB to treat multibyte characters as binary:

```
=> SELECT INSTRB('aébc', 'b');
INSTRB

4
(1 row)
```

## INSTRB

Searches *string* for *substring* and returns an integer indicating the octet position within string that is the first *occurrence*. The return value is based on the octet position of the identified byte.

Behavior type

[Immutable](#)

Syntax

```
INSTRB (string , substring [, position [, occurrence]])
```

Arguments

### **string**

Is the text expression to search.

### **substring**

Is the string to search for.

### **position**

Is a nonzero integer indicating the character of string where Vertica begins the search. If position is negative, then Vertica counts backward from the end of string and then searches backward from the resulting position. The first byte of string occupies the default position 1, and position cannot be 0.

### **occurrence**

Is an integer indicating which occurrence of string Vertica searches. The value of occurrence must be positive (greater than 0), and the default is 1.

Notes

Both *position* and *occurrence* must be of types that can resolve to an integer. The default values of both parameters are 1, meaning Vertica begins searching at the first byte of string for the first occurrence of substring. The return value is relative to the beginning of string, regardless of the value of position, and is expressed in octets.

If the search is unsuccessful (that is, if substring does not appear *\* occurrence* \*times after the *\* position* \*character of *\* string*, \*then the return value is 0.

Examples

```
=> SELECT INSTRB('straße', 'ß');
INSTRB

5
(1 row)
```

See also

- [INSTR](#)

## ISUTF8

Tests whether a string is a valid UTF-8 string. Returns true if the string conforms to UTF-8 standards, and false otherwise. This function is useful to test strings for UTF-8 compliance before passing them to one of the regular expression functions, such as [REGEXP\\_LIKE](#), which expect UTF-8 characters by default.

ISUTF8 checks for invalid UTF8 byte sequences, according to UTF-8 rules:

- invalid bytes
- an unexpected continuation byte
- a start byte not followed by enough continuation bytes
- an Overload Encoding

The presence of an invalid UTF-8 byte sequence results in a return value of false.

To coerce a string to UTF-8, use [MAKEUTF8](#).

Syntax

```
ISUTF8(string);
```

Arguments

***string***

The string to test for UTF-8 compliance.

Examples

```
=> SELECT ISUTF8(E'\xC2\xBF'); -- UTF-8 INVERTED QUESTION MARK ISUTF8

t
(1 row)

=> SELECT ISUTF8(E'\xC2\xC0'); -- UNDEFINED UTF-8 CHARACTER
ISUTF8

f
(1 row)
```

JARO\_DISTANCE

Calculates and returns the [Jaro similarity](#), an edit distance between two sequences. It is useful for queries designed for short strings, such as finding similar names. Also see [Jaro-Winkler distance](#), which adds a prefix scale favoring strings that match in the beginning, and [edit distance](#), which returns the Levenshtein distance between two strings.

Behavior type

[Immutable](#)

Syntax

```
JARO_DISTANCE (string-expression1, string-expression2)
```

Arguments

***string-expression1*** , ***string-expression2***

The two VARCHAR expressions to compare. Neither can be NULL.

Example

Return only the names with a Jaro distance from 'rode' that is greater than 0.6:

```
=> SELECT name FROM names WHERE JARO_DISTANCE('rode', name) > 0.6;
name

fred
frieda
rodgers
rogers
(4 rows)
```

JARO\_WINKLER\_DISTANCE

Calculates and returns the [Jaro-Winkler similarity](#), an edit distance between two sequences. It is useful for queries designed for short strings, such as finding similar names. It is a variant of the [Jaro distance](#) metric, to which it adds a prefix scale giving more favorable ratings for strings that match from the beginning. See also [edit distance](#), which returns the Levenshtein distance between two strings.

Behavior type

[Immutable](#)

Syntax

```
JARO_WINKLER_DISTANCE (string-expression1 , string-expression2 [USING PARAMETERS prefix_scale=scale, prefix_length=length])
```

Arguments

***string-expression1* , *string-expression2***

The two VARCHAR expressions to compare. Neither can be NULL.

Parameters

***scale***

A FLOAT specifying the scale value by which to weight the importance of matching prefixes. Optional.

default = 0.1

***length***

An non-negative INT representing the maximum matching prefix length. Optional.

default = 4

Examples

Return only the names with a Jaro-Winkler distance from 'rode' that is greater than 0.6:

```
=> SELECT name FROM names WHERE JARO_WINKLER_DISTANCE('rode', name) > 0.6;
name

fred
frieda
rodgers
rogers
(4 rows)
```

The Jaro-Winkler distance between 'help' and 'hello' given a [prefix\\_scale](#) of 0.1 and [prefix\\_length](#) of 0 is 0.7833333333333333:

```
=> select JARO_WINKLER_DISTANCE('help', 'hello' USING PARAMETERS prefix_scale=0.1, prefix_length=0);
jaro_winkler_distance

0.7833333333333333
(1 row)
```

LEAST

Returns the smallest value in a list of expressions of any data type. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Stable](#)

Syntax

```
LEAST ({ * | expression[,...] })
```

Arguments

\* | ***expression*** [...]

The expressions to evaluate, one of the following:

- \* (asterisk)  
Evaluates all columns in the queried table.
- ***expression***  
An expression of any data type. Functions that are included in ***expression*** must be deterministic.

Examples

LEASTB returns 5 as the smallest value in the list:

```
=> SELECT LEASTB(7, 5, 10);
LEASTB

 5
(1 row)
```

If you put quotes around the integer expressions, LEASTB compares the values as strings and returns '10' as the smallest value:

```
=> SELECT LEASTB('7', '5', '10');
LEASTB

 10
(1 row)
```

LEAST returns 1.5, as INTEGER 2 is implicitly cast to FLOAT:

```
=> SELECT LEAST(2, 1.5);
LEAST

 1.5
(1 row)
```

LEAST queries all columns in a view based on the VMart table `product_dimension`, and returns the smallest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
CREATE VIEW
=> SELECT shelf_height, shelf_width, shelf_depth, least(*) FROM query1 WHERE shelf_height = 5;
shelf_height | shelf_width | shelf_depth | least
-----+-----+-----+-----
 5 | 3 | 4 | 3
 5 | 4 | 3 | 3
 5 | 1 | 4 | 1
 5 | 4 | 1 | 1
 5 | 2 | 4 | 2
 5 | 2 | 3 | 2
 5 | 1 | 3 | 1
 5 | 1 | 3 | 1
 5 | 5 | 1 | 1
 5 | 2 | 4 | 2
 5 | 4 | 5 | 4
 5 | 2 | 4 | 2
 5 | 4 | 4 | 4
 5 | 3 | 4 | 3
...
```

See also

[GREATEST](#)

LEASTB

Returns the smallest value in a list of expressions of any data type, using binary ordering. All data types in the list must be the same or [compatible](#). A NULL value in any one of the expressions returns NULL. Results can vary, depending on the locale's collation setting.

Behavior type

[Immutable](#)

Syntax

```
LEASTB ({ * | expression[,...] })
```

Arguments

\* | ***expression*** [...]

The expressions to evaluate, one of the following:

- **\*** (asterisk)  
Evaluates all columns in the queried table.
- ***expression***

An expression of any data type. Functions that are included in *expression* must be deterministic.

## Examples

The following command selects *strasse* as the smallest value in the list:

```
=> SELECT LEASTB('straße', 'strasse');
LEASTB

strasse
(1 row)
```

LEASTB returns 5 as the smallest value in the list:

```
=> SELECT LEAST(7, 5, 10);
LEAST

5
(1 row)
```

If you put quotes around the integer expressions, LEAST compares the values as strings and returns '10' as the smallest value:

```
=> SELECT LEASTB('7', '5', '10');
LEAST

10
(1 row)
```

The next example returns 1.5, as INTEGER 2 is implicitly cast to FLOAT:

```
=> SELECT LEASTB(2, 1.5);
LEASTB

1.5
(1 row)
```

LEASTB queries all columns in a view based on the VMart table *product\_dimension*, and returns the smallest value in each row:

```
=> CREATE VIEW query1 AS SELECT shelf_width, shelf_height, shelf_depth FROM product_dimension;
CREATE VIEW
=> SELECT shelf_height, shelf_width, shelf_depth, leastb(*) FROM query1 WHERE shelf_height = 5;
shelf_height | shelf_width | shelf_depth | leastb
-----+-----+-----+-----
5 | 3 | 4 | 3
5 | 4 | 3 | 3
5 | 1 | 4 | 1
5 | 4 | 1 | 1
5 | 2 | 4 | 2
5 | 2 | 3 | 2
5 | 1 | 3 | 1
5 | 1 | 3 | 1
5 | 5 | 1 | 1
5 | 2 | 4 | 2
5 | 4 | 5 | 4
5 | 2 | 4 | 2
5 | 4 | 4 | 4
5 | 3 | 4 | 3
5 | 5 | 4 | 4
5 | 5 | 1 | 1
5 | 3 | 1 | 1
...
```

See also

[GREATESTB](#)

[LEFT](#)

Returns the specified characters from the left side of a string.

Behavior type

[Immutable](#)

Syntax

```
LEFT (string-expr, length)
```

Arguments

***string-expr***

The string expression to return.

***length***

An integer value that specifies how many characters to return.

Examples

```
=> SELECT LEFT('vertica', 3);
```

```
LEFT
```

```

```

```
ver
```

```
(1 row)
```

```
SELECT DISTINCT(
```

```
 LEFT (customer_name, 4)) FnameTruncated
```

```
FROM customer_dimension ORDER BY FnameTruncated LIMIT 10;
```

```
FnameTruncated
```

```

```

```
Alex
```

```
Amer
```

```
Amy
```

```
Anna
```

```
Barb
```

```
Ben
```

```
Bett
```

```
Bria
```

```
Carl
```

```
Crai
```

```
(10 rows)
```

See also

[SUBSTR](#)

[LENGTH](#)

Returns the length of a string. The behavior of [LENGTH](#) varies according to the input data type:

- CHAR and VARCHAR: Identical to [CHARACTER\\_LENGTH](#), returns the string length in UTF-8 characters, .
- CHAR: Strips padding.
- BINARY and VARBINARY: Identical to [OCTET\\_LENGTH](#), returns the string length in bytes (octets).

Behavior type

[Immutable](#)

Syntax

```
LENGTH (expression)
```

Arguments

***expression***

String to evaluate, one of the following: CHAR, VARCHAR, BINARY or VARBINARY.

Examples

Statement	Returns
<pre>SELECT LENGTH('1234 '::CHAR(10));</pre>	4

<code>SELECT LENGTH('1234 '::VARCHAR(10));</code>	6
<code>SELECT LENGTH('1234 '::BINARY(10));</code>	10
<code>SELECT LENGTH('1234 '::VARBINARY(10));</code>	6
<code>SELECT LENGTH(NULL::CHAR(10)) IS NULL;</code>	t

See also

[BIT\\_LENGTH](#)

LOWER

Takes a string value and returns a VARCHAR value converted to lowercase.

Behavior type

[stable](#)

Syntax

```
LOWER (expression)
```

Arguments

***expression***

CHAR or VARCHAR string to convert, where the string width is  $\leq 65000$  octets.

Important

In practice, *expression* should not exceed 32,500 octets. LOWER does not use the locale's collation setting—for example, `collation=binary`—to identify its encoding; rather, it treats the input argument as a UTF-8 encoded string. The UTF-8 representation of the input value might be double its original width. As a result, LOWER returns an error if the input value exceeds 32,500 octets.

Note also that if *expression* is a table column, LOWER calculates its size from the column's defined width, and not from the column data. If the column width is greater than VARCHAR(32500), Vertica returns an error.

Examples

```
=> SELECT LOWER('AbCdEfG');
```

```
LOWER
```

```

```

```
abcdefg
```

```
(1 row)
```

```
=> SELECT LOWER('The Bat In The Hat');
```

```
LOWER
```

```

```

```
the bat in the hat
```

```
(1 row)
```

```
=> SELECT LOWER('ÉTUDIANT');
```

```
LOWER
```

```

```

```
étudiant
```

```
(1 row)
```

LOWERB

Returns a character string with each ASCII character converted to lowercase. Multi-byte characters are skipped and not converted.

Behavior type

[Immutable](#)

Syntax

```
LOWERB (expression)
```

Arguments

### **expression**

CHAR or VARCHAR string to convert

#### Examples

In the following example, the multi-byte UTF-8 character É is not converted to lowercase:

```
=> SELECT LOWERB('ÉTUDIANT');
LOWERB

Étudiant
(1 row)

=> SELECT LOWER('ÉTUDIANT');
LOWER

étudiant
(1 row)

=> SELECT LOWERB('AbCdEfG');
LOWERB

abcdefg
(1 row)

=> SELECT LOWERB('The Vertica Database');
LOWERB

the vertica database
(1 row)
```

#### LPAD

Returns a VARCHAR value representing a string of a specific length filled on the left with specific characters.

#### Behavior type

[Immutable](#)

#### Syntax

```
LPAD (expression , length [, fill])
```

#### Arguments

##### **expression**

(CHAR OR VARCHAR) specifies the string to fill

##### **length**

(INTEGER) specifies the number of characters to return

##### **fill**

(CHAR OR VARCHAR) specifies the repeating string of characters with which to fill the output string. The default is the space character.

#### Examples

```
=> SELECT LPAD('database', 15, 'xyz');
LPAD

xyzxyzdatabase
(1 row)
```

If the string is already longer than the specified length it is truncated on the right:

```
=> SELECT LPAD('establishment', 10, 'abc');
LPAD

establishm
(1 row)
```

## LTRIM

Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning).

Behavior type

[Immutable](#)

Syntax

```
LTRIM (expression [, characters])
```

Arguments

### ***expression***

(CHAR or VARCHAR) is the string to trim

### ***characters***

(CHAR or VARCHAR) specifies the characters to remove from the left side of *expression* . The default is the space character.

Examples

```
=> SELECT LTRIM('zzzyyyyyxxxxxxxxtrim', 'xyz');
LTRIM

trim
(1 row)
```

See also

- [BTRIM](#)
- [RTRIM](#)
- [TRIM](#)

## MAKEUTF8

Coerces a string to UTF-8 by removing or replacing non-UTF-8 characters.

MAKEUTF8 flags invalid UTF-8 characters byte by byte. For example, the byte sequence `0xE0 0x7F 0x80` is an invalid three-byte UTF-8 sequence, but the middle byte, `0x7F` , is a valid one-byte UTF-8 character. In this example, `0x7F` is preserved and the other two bytes are removed or replaced.

Syntax

```
MAKEUTF8(string-expression [USING PARAMETERS param=value]);
```

Arguments

### ***string-expression***

The string expression to evaluate for non-UTF-8 characters

Parameters

### **replacement\_string**

Specifies the VARCHAR(16) string that MAKEUTF8 uses to replace each non-UTF-8 character that it finds in *string-expression* . If this parameter is omitted, non-UTF-8 characters are removed. For example, the following SQL specifies to replace all non-UTF characters in the `name` column with the string `^` :

```
=> SELECT MAKEUTF8(name USING PARAMETERS replacement_string='^') FROM people;
```

## MD5

Calculates the MD5 hash of string, returning the result as a VARCHAR string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
MD5 (string)
```

Arguments

### ***string***

Is the argument string.

Examples

```
=> SELECT MD5('123');
 MD5
```

```

202cb962ac59075b964b07152d234b70
```

```
(1 row)
```

```
=> SELECT MD5('Vertica'::bytea);
 MD5
```

```

fc45b815747d8236f9f6fdb9c2c3f676
```

```
(1 row)
```

See also

- [SHA1](#)
- [SHA224](#)
- [SHA256](#)
- [SHA384](#)
- [SHA512](#)

## OCTET\_LENGTH

Takes one argument as an input and returns the string length in octets for all string types.

Behavior type

[Immutable](#)

Syntax

```
OCTET_LENGTH (expression)
```

Arguments

***expression***

(CHAR or VARCHAR or BINARY or VARBINARY) is the string to measure.

Notes

- If the data type of *expression* is a CHAR, VARCHAR or VARBINARY, the result is the same as the actual length of *expression* in octets. For CHAR, the length does not include any trailing spaces.
- If the data type of *expression* is BINARY, the result is the same as the fixed-length of *expression*.
- If the value of *expression* is NULL, the result is NULL.

Examples

Expression	Result
<code>SELECT OCTET_LENGTH(CHAR(10) '1234 ');</code>	4
<code>SELECT OCTET_LENGTH(CHAR(10) '1234');</code>	4
<code>SELECT OCTET_LENGTH(CHAR(10) ' 1234');</code>	6
<code>SELECT OCTET_LENGTH(VARCHAR(10) '1234 ');</code>	6
<code>SELECT OCTET_LENGTH(VARCHAR(10) '1234 ');</code>	5
<code>SELECT OCTET_LENGTH(VARCHAR(10) '1234');</code>	4
<code>SELECT OCTET_LENGTH(VARCHAR(10) ' 1234');</code>	7
<code>SELECT OCTET_LENGTH('abc'::VARBINARY);</code>	3
<code>SELECT OCTET_LENGTH(VARBINARY 'abc');</code>	3

SELECT OCTET_LENGTH(VARBINARY 'abc');	5
SELECT OCTET_LENGTH(BINARY(6) 'abc');	6
SELECT OCTET_LENGTH(VARBINARY "");	0
SELECT OCTET_LENGTH("::BINARY);	1
SELECT OCTET_LENGTH(null::VARBINARY);	
SELECT OCTET_LENGTH(null::BINARY);	

See also

- [BIT\\_LENGTH](#)
- [CHARACTER\\_LENGTH](#)
- [LENGTH](#)

## OVERLAY

Replaces part of a string with another string and returns the new string value as a VARCHAR.

Behavior type

[Immutable](#) if using OCTETS, [Stable](#) otherwise

Syntax

```
OVERLAY (input-string PLACING replace-string FROM position [FOR extent] [USING { CHARACTERS | OCTETS }])
```

Arguments

### *input-string*

The string to process, of type CHAR or VARCHAR.

### *replace-string*

The string to replace the specified substring of *input-string*, of type CHAR or VARCHAR.

### *position*

Integer  $\geq 1$  that specifies the first character or octet of *input-string* to overlay *replace-string*.

### *extent*

Integer that specifies how many characters or octets of *input-string* to overlay with *replace-string*. If omitted, OVERLAY uses the length of *replace-string*.

For example, compare the following calls to OVERLAY:

- OVERLAY omits **FOR** clause. The number of characters replaced in the input string equals the number of characters in replacement string **ABC**:

```
dbadmin=> SELECT OVERLAY ('123456789' PLACING 'ABC' FROM 5);
overlay

1234ABC89
(1 row)
```

- OVERLAY includes a **FOR** clause that specifies to replace four characters in the input string with the replacement string. The replacement string is three characters long, so OVERLAY returns a string that is one character shorter than the input string:

```
=> SELECT OVERLAY ('123456789' PLACING 'ABC' FROM 5 FOR 4);
overlay

1234ABC9
(1 row)
```

- OVERLAY includes a **FOR** clause that specifies to replace -2 characters in the input string with the replacement string. The function returns a string that is two characters longer than the input string:

```
=> SELECT OVERLAY ('123456789' PLACING 'ABC' FROM 5 FOR -2);
overlay

1234ABC3456789
(1 row)
```

## USING CHARACTERS | OCTETS

Specifies whether OVERLAY uses characters (default) or octets.

### Note

If you specify **USING OCTETS**, Vertica calls the [OVERLAYB](#) function.

## Examples

```
=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2);
overlay

1xxx56789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'XXX' FROM 2 USING OCTETS);
overlayb

1XXX56789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 4);
overlay

1xxx6789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 5);
overlay

1xxx789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 6);
overlay

1xxx89
(1 row)
```

## OVERLAYB

Replaces part of a string with another string and returns the new string as an octet value.

The OVERLAYB function treats the multibyte character string as a string of octets (bytes) and use octet numbers as incoming and outgoing position specifiers and lengths. The strings themselves are type VARCHAR, but they treated as if each byte was a separate character.

Behavior type

[Immutable](#)

Syntax

```
OVERLAYB (input-string, replace-string, position [, extent])
```

Arguments

***input-string***

The string to process, of type CHAR or VARCHAR.

***replace-string***

The string to replace the specified substring of *input-string*, of type CHAR or VARCHAR.

### **position**

Integer  $\geq 1$  that specifies the first octet of\* *input-string* \* to overlay *replace-string*.

### **extent**

Integer that specifies how many octets of *input-string* to overlay with *replace-string*. If omitted, OVERLAY uses the length of *replace-string*.

### Examples

```
=> SELECT OVERLAYB('123456789', 'ééé', 2);
OVERLAYB
```

```

1ééé89
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'BBB', 2);
OVERLAYB
```

```

1BBB89
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2);
OVERLAYB
```

```

1xxx56789
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2, 4);
OVERLAYB
```

```

1xxx6789
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2, 5);
OVERLAYB
```

```

1xxx789
```

```
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'xxx', 2, 6);
OVERLAYB
```

```

1xxx89
```

```
(1 row)
```

### POSITION

Returns an INTEGER value representing the character location of a specified substring with a string (counting from one).

### Behavior type

[Immutable](#)

### Syntax 1

```
POSITION (substring IN string [USING { CHARACTERS | OCTETS }])
```

### Arguments

#### **substring**

(CHAR or VARCHAR) is the substring to locate

#### **string**

(CHAR or VARCHAR) is the string in which to locate the substring

#### **USING CHARACTERS | OCTETS**

Determines whether the position is reported by using characters (the default) or octets.

### Syntax 2

```
POSITION (substring IN string)
```

### Arguments

#### **substring**

(VARBINARY) is the substring to locate

**string**

(VARBINARY) is the string in which to locate the substring

Notes

- When the string and substring are CHAR or VARCHAR, the return value is based on either the character or octet position of the substring.
- When the string and substring are VARBINARY, the return value is always based on the octet position of the substring.
- The string and substring must be consistent. Do not mix VARBINARY with CHAR or VARCHAR.
- POSITION is similar to [STRPOS](#) although POSITION allows finding by characters and by octet.
- If the string is not found, the return value is zero.

Examples

```
=> SELECT POSITION('é' IN 'étudiant' USING CHARACTERS);
position

 1
(1 row)
=> SELECT POSITION('ß' IN 'straße' USING OCTETS);
positionb

 5
(1 row)
=> SELECT POSITION('c' IN 'abcd' USING CHARACTERS);
position

 3
(1 row)
=> SELECT POSITION(VARBINARY '456' IN VARBINARY '123456789');
position

 4
(1 row)
SELECT POSITION('n' in 'León') as 'default',
 POSITIONB('León', 'n') as 'POSITIONB',
 POSITION('n' in 'León' USING CHARACTERS) as 'pos_chars',
 POSITION('n' in 'León' USING OCTETS) as 'pos_oct', INSTR('León','n'),
 INSTRB('León','n'), REGEXP_INSTR('León','n');
default | POSITIONB | pos_chars | pos_oct | INSTR | INSTRB | REGEXP_INSTR
-----+-----+-----+-----+-----+-----+-----
 4 | 5 | 4 | 5 | 4 | 5 | 4
(1 row)
```

POSITIONB

Returns an INTEGER value representing the octet location of a specified substring with a string (counting from one).

Behavior type

[Immutable](#)

Syntax

```
POSITIONB (string, substring)
```

Arguments

**string**

(CHAR or VARCHAR) is the string in which to locate the substring

**substring**

(CHAR or VARCHAR) is the substring to locate

Examples

```
=> SELECT POSITIONB('straße', 'ße');
```

```
POSITIONB
```

```

5
```

```
(1 row)
```

```
=> SELECT POSITIONB('étudiant', 'é');
```

```
POSITIONB
```

```

1
```

```
(1 row)
```

## QUOTE\_IDENT

Returns the specified string argument in the format required to use the string as an [identifier](#) in an SQL statement. Quotes are added as needed—for example, if the string contains non-identifier characters or is an SQL or [Vertica-reserved](#) keyword:

- **time**
- **Next week**
- **SELECT**

Embedded double quotes are doubled.

### Note

- SQL identifiers such as table and column names are stored as created, and references to them are resolved using case-insensitive compares. Thus, you do not need to double-quote mixed-case identifiers.
- Vertica quotes all reserved keywords, even if unused.

Behavior type

[Immutable](#)

Syntax

```
QUOTE_IDENT('string')
```

Arguments

**string**

String to quote

Examples

Quoted identifiers are case-insensitive, and Vertica does not supply the quotes:

```
=> SELECT QUOTE_IDENT('VertlcA');
```

```
QUOTE_IDENT
```

```

VertlcA
```

```
(1 row)
```

```
=> SELECT QUOTE_IDENT('Vertica database');
```

```
QUOTE_IDENT
```

```

"Vertica database"
```

```
(1 row)
```

Embedded double quotes are doubled:

```
=> SELECT QUOTE_IDENT('Vertica "!" database');
```

```
QUOTE_IDENT
```

```

"Vertica ""!"" database"
```

```
(1 row)
```

The following example uses the SQL keyword SELECT, so results are double quoted:

```
=> SELECT QUOTE_IDENT('select');
QUOTE_IDENT

"select"
(1 row)
```

See also

- [QUOTE\\_LITERAL](#)
- [QUOTE\\_NULLABLE](#)

## QUOTE\_LITERAL

Returns the given string suitably quoted for use as a string literal in a SQL statement string. Embedded single quotes and backslashes are doubled. As per the SQL standard, the function recognizes two consecutive single quotes within a string literal as a single quote character.

Behavior type

[Immutable](#)

Syntax

```
QUOTE_LITERAL (string)
```

Arguments

### *string-expression*

Argument that resolves to one or more strings to format as string literals.

Examples

In the following example, the first query returns no first name for Cher or Sting; the second query uses QUOTE\_LITERAL, which sets off string values with single quotes, including empty strings. In this case, `fname` for Sting is set to an empty string ( `"` ), while `fname` for Cher is empty, indicating that it is set to null value:

```
=> SELECT * FROM lead_vocalists ORDER BY Iname ASC;
fname | Iname | band
-----+-----+-----
 | Cher | ["Sonny and Cher"]
Mick | Jagger | ["Rolling Stones"]
Diana | Ross | ["Supremes"]
Grace | Slick | ["Jefferson Airplane","Jefferson Starship"]
 | Sting | ["Police"]
Stevie | Winwood | ["Spencer Davis Group","Traffic","Blind Faith"]
(6 rows)

=> SELECT QUOTE_LITERAL (fname) "First Name", QUOTE_NULLABLE (Iname) "Last Name", band FROM lead_vocalists ORDER BY Iname ASC;
First Name | Last Name | band
-----+-----+-----
 | 'Cher' | ["Sonny and Cher"]
'Mick' | 'Jagger' | ["Rolling Stones"]
'Diana' | 'Ross' | ["Supremes"]
'Grace' | 'Slick' | ["Jefferson Airplane","Jefferson Starship"]
" | 'Sting' | ["Police"]
'Stevie' | 'Winwood' | ["Spencer Davis Group","Traffic","Blind Faith"]
(6 rows)
```

See also

- [Character string literals](#)
- [QUOTE\\_NULLABLE](#)

## QUOTE\_NULLABLE

Returns the given string suitably quoted for use as a string literal in an SQL statement string; or if the argument is null, returns the unquoted string `NULL` . Embedded single-quotes and backslashes are properly doubled.

Behavior type

## [Immutable](#)

### Syntax

```
QUOTE_NULLABLE (string-expression)
```

### Arguments

#### ***string-expression***

Argument that resolves to one or more strings to format as string literals. If *string-expression* resolves to null value, QUOTE\_NULLABLE returns **NULL**.

### Examples

The following examples use the table `lead_vocalists`, where the first names (`fname`) for Cher and Sting are set to **NULL** and an empty string, respectively

```
=> SELECT * from lead_vocalists ORDER BY lname DESC;
fname | lname | band
-----+-----+-----
Stevie | Winwood | ["Spencer Davis Group","Traffic","Blind Faith"]
 | Sting | ["Police"]
Grace | Slick | ["Jefferson Airplane","Jefferson Starship"]
Diana | Ross | ["Supremes"]
Mick | Jagger | ["Rolling Stones"]
 | Cher | ["Sonny and Cher"]
(6 rows)

=> SELECT * FROM lead_vocalists WHERE fname IS NULL;
fname | lname | band
-----+-----+-----
 | Cher | ["Sonny and Cher"]
(1 row)

=> SELECT * FROM lead_vocalists WHERE fname = "";
fname | lname | band
-----+-----+-----
 | Sting | ["Police"]
(1 row)
```

The following query uses QUOTE\_NULLABLE. Like [QUOTE\\_LITERAL](#), QUOTE\_NULLABLE sets off string values with single quotes, including empty strings. Unlike QUOTE\_LITERAL, QUOTE\_NULLABLE outputs **NULL** for null values:

```
=> SELECT QUOTE_NULLABLE (fname) "First Name", QUOTE_NULLABLE (lname) "Last Name", band FROM lead_vocalists ORDER BY fname DESC;
First Name | Last Name | band
-----+-----+-----
NULL | 'Cher' | ["Sonny and Cher"]
'Stevie' | 'Winwood' | ["Spencer Davis Group","Traffic","Blind Faith"]
'Mick' | 'Jagger' | ["Rolling Stones"]
'Grace' | 'Slick' | ["Jefferson Airplane","Jefferson Starship"]
'Diana' | 'Ross' | ["Supremes"]
" | 'Sting' | ["Police"]
(6 rows)
```

See also

[Character string literals](#)

### REPEAT

Replicates a string the specified number of times and concatenates the replicated values as a single string. The return value takes on the data type of the string argument. Return values for non-LONG data types and LONG data types can be up to 65000 and 32000000 bytes in length, respectively. If the length of *string \* count* exceeds these limits, Vertica silently truncates the results.

Behavior type

## [Immutable](#)

### Syntax

```
REPEAT ('string', count)
```

Arguments

**string**

The string to repeat, one of the following:

- CHAR
- VARCHAR
- BINARY
- VARBINARY
- LONG VARCHAR
- LONG VARBINARY

**count**

An integer expression that specifies how many times to repeat *string*.

Examples

The following example repeats **vmart** three times:

```
=> SELECT REPEAT ('vmart', 3);
 REPEAT

vmartvmartvmart
(1 row)
```

REPLACE

Replaces all occurrences of characters in a string with another set of characters.

Behavior type

[Immutable](#)

Syntax

```
REPLACE ('string', 'target', 'replacement')
```

Arguments

**string**

The string to modify.

**target**

The characters in *string* to replace.

**replacement**

The characters to replace *target*.

Examples

```
=> SELECT REPLACE('Documentation%20Library', '%20', '');
 REPLACE

Documentation Library
(1 row)

=> SELECT REPLACE('This & That', '&', 'and');
 REPLACE

This and That
(1 row)

=> SELECT REPLACE('straße', 'ß', 'ss');
 REPLACE

strasse
(1 row)
```

## RIGHT

Returns the specified characters from the right side of a string.

Behavior type

[Immutable](#)

Syntax

```
RIGHT (string-expr, length)
```

Arguments

***string-expr***

The string expression to return.

***length***

An integer value that specifies how many characters to return.

Examples

The following query returns the last three characters of the string 'vertica':

```
=> SELECT RIGHT('vertica', 3);
RIGHT

ica
(1 row)
```

The following query queries date column `date_ordered` from table `store.store_orders_fact` . It coerces the dates to strings and extracts the last five characters from each string. It then returns all distinct strings:

```
SELECT DISTINCT(
 RIGHT(date_ordered::varchar, 5)) MonthDays
FROM store.store_orders_fact ORDER BY MonthDays;
MonthDays

01-01
01-02
01-03
01-04
01-05
01-06
01-07
01-08
01-09
01-10
02-01
02-02
02-03
...
11-08
11-09
11-10
12-01
12-02
12-03
12-04
12-05
12-06
12-07
12-08
12-09
12-10
(120 rows)
```

See also

## [SUBSTR](#)

### RPAD

Returns a VARCHAR value representing a string of a specific length filled on the right with specific characters.

Behavior type

### [Immutable](#)

Syntax

```
RPAD (expression , length [, fill])
```

Arguments

#### **expression**

(CHAR OR VARCHAR) specifies the string to fill

#### **length**

(INTEGER) specifies the number of characters to return

#### **fill**

(CHAR OR VARCHAR) specifies the repeating string of characters with which to fill the output string. The default is the space character.

Examples

```
=> SELECT RPAD('database', 15, 'xzy');
 RPAD

databasexzyxzyx
(1 row)
```

If the string is already longer than the specified length it is truncated on the right:

```
=> SELECT RPAD('database', 6, 'xzy');
 RPAD

databa
(1 row)
```

## RTRIM

Returns a VARCHAR value representing a string with trailing blanks removed from the right side (end).

Behavior type

### [Immutable](#)

Syntax

```
RTRIM (expression [, characters])
```

Arguments

#### **expression**

(CHAR or VARCHAR) is the string to trim

#### **characters**

(CHAR or VARCHAR) specifies the characters to remove from the right side of *expression* . The default is the space character.

Examples

```
=> SELECT RTRIM('trimzzzyyyyyyxxxxxxxx', 'xyz');
 RTRIM

trim
(1 row)
```

See also

- [BTRIM](#)
- [LTRIM](#)
- [TRIM](#)

Uses the US Secure Hash Algorithm 1 to calculate the **SHA1** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA1 (string)
```

Arguments

***string***

The **VARCHAR** or **VARBINARY** string to be calculated.

Examples

The following examples calculate the **SHA1** hash of the provided strings:

```
=> SELECT SHA1('123');
 SHA1

40bd001563085fc35165329ea1ff5c5ecbdbbfeef
(1 row)
```

```
=> SELECT SHA1('Vertica'::bytea);
 SHA1

ee2cff8d3444995c6c301546c4fc5ee152d77c11
(1 row)
```

- [SHA512](#)

SHA224

Uses the US Secure Hash Algorithm 2 to calculate the **SHA224** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA224 (string)
```

Arguments

***string***

The **VARCHAR** or **VARBINARY** string to be calculated.

Examples

The following examples calculate the **SHA224** hash of the provided strings:

```
=> SELECT SHA224('abc');
 SHA224

78d8045d684abd2eece923758f3cd781489df3a48e1278982466017f
(1 row)
```

```
=> SELECT SHA224('Vertica'::bytea);
 SHA224

135ac268f64ff3124aeeebc3cc0af0a29fd600a3be8e29ed97e45e25
(1 row)
```

```
=> SELECT sha224("::varbinary) = 'd14a028c2a3a2bc9476102bb288234c415a2b01f828ea62ac5b3e42f' AS "TRUE";
TRUE

t
(1 row)
```

- [SHA512\(\)](#)

### SHA256

Uses the US Secure Hash Algorithm 2 to calculate the **SHA256** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA256 (string)
```

Arguments

**string**

The **VARCHAR** or **VARBINARY** string to be calculated.

Examples

The following examples calculate the **SHA256** hash of the provided strings:

```
=> SELECT SHA256('abc');
 SHA256

a665a45920422f9d417e4867efdc4fb8a04a1f3fff1fa07e998e86f7f7a27ae3
(1 row)
```

```
=> SELECT SHA256('Vertica'::bytea);
 SHA256

9981b0b7df9f5be06e9e1a7f4ae2336a7868d9ab522b9a6ca6a87cd9ed95ba53
(1 row)
```

```
=> SELECT sha256("") = 'e3b0c44298fc1c149afbf4c8996fb92427ae41e4649b934ca495991b7852b855' AS "TRUE";
TRUE

t
(1 row)
```

### SHA384

Uses the US Secure Hash Algorithm 2 to calculate the **SHA384** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

Behavior type

[Immutable](#)

Syntax

```
SHA384 (string)
```

## Arguments

### **string**

The **VARCHAR** or **VARBINARY** string to be calculated.

## Examples

The following examples calculate the **SHA384** hash of the provided strings:

```
=> SELECT SHA384('123');
 SHA384

9a0a82f0c0cf31470d7affede3406cc9aa8410671520b727044eda15b4c25532a9b5cd8aaf9cec4919d76255b6bfb00f
(1 row)
```

```
=> SELECT SHA384('Vertica::bytea');
 SHA384

3431a717dc3289862bbd636a064d26980b47ebe4684b800cff4756f0c24985866ef97763eafd548fedb0ce28722c96bb
(1 row)
```

## See also

## SHA512

Uses the US Secure Hash Algorithm 2 to calculate the **SHA512** hash of string. Returns the result as a **VARCHAR** string in hexadecimal.

## Behavior type

[Immutable](#)

## Syntax

```
SHA512 (string)
```

## Arguments

### **string**

The **VARCHAR** or **VARBINARY** string to be calculated.

## Examples

The following examples calculate the **SHA512** hash of the provided strings:

```
=> SELECT SHA512('123');
 SHA512

3c9909afec25354d551dae21590bb26e38d53f2173b8d3dc3eee4c047e7ab1c1eb8b85103e3be7ba613b31bb5c9c36214dc9f14a42fd7a2fdb84856bca5c44c2
(1 row)
```

```
=> SELECT SHA512('Vertica::bytea');
 SHA512

c4ee2b2d17759226a3897c9c30d7c6df1145c4582849bb5191ee140bce05b83d3d869890cc3619b534fea6f97ff28a739d8b568a5ade66e756b3243ef97d3f00
(1 row)
```

## See also

- [MD5](#)
- [SHA1](#)
- [SHA224](#)
- [SHA256](#)
- [SHA384](#)

## SOUNDEX

Takes a VARCHAR argument and returns a four-character code that enables comparison of that argument with other SOUNDEX-encoded strings that are spelled differently in English, but are phonetically similar. SOUNDEX implements an algorithm that was developed by Robert C. Russell and Margaret King Odell, and is described in [The Art of Computer Programming, Vol. 3](#).

Behavior type

[Immutable](#)

Syntax

```
SOUNDEX (string-expression)
```

Arguments

***string-expression***

The VARCHAR expression to encode.

Soundex encoding algorithm

Vertica uses the following Soundex encoding algorithm, which complies with most SQL implementations:

1. Save the first letter. Map all occurrences of a, e, i, o, u, y, h, w to zero (0).
2. Replace all consonants (include the first letter) with digits:
  - b, f, p, v → 1
  - c, g, j, k, q, s, x, z → 2
  - d, t → 3
  - l → 4
  - m, n → 5
  - r → 6
3. Replace all adjacent same digits with one digit, and then remove all zero (0) digits
4. If the saved letter's digit is the same as the resulting first digit, remove the digit (keep the letter).
5. Append 3 zeros if result contains less than 3 digits. Remove all except first letter and 3 digits after it.

### Note

Encoding ignores all non-alphabetic characters—for example, the apostrophe in O'Connor.

Examples

Find last names in the `employee_dimension` table that are phonetically similar to `Lee` :

```
SELECT employee_last_name, employee_first_name, employee_state
FROM public.employee_dimension
WHERE SOUNDEX(employee_last_name) = SOUNDEX('Lee')
ORDER BY employee_state, employee_last_name, employee_first_name;
```

```
Lea | James | AZ
Li | Sam | AZ
Lee | Darlene | CA
Lee | Juanita | CA
Li | Amy | CA
Li | Barbara | CA
Li | Ben | CA
...
```

See also

[SOUNDEX\\_MATCHES](#)

SOUNDEX\_MATCHES

Compares the Soundex encodings of two strings. The function then returns an integer that indicates the number of matching characters, in the same order. The return value is 0 to 4 inclusive, where 0 indicates no match, and 4 an exact match.

For details on how Vertica implements Soundex encoding, see [Soundex Encoding Algorithm](#).

Behavior type

[Immutable](#)

Syntax

```
SOUNDEX_MATCHES (string-expression1, string-expression2)
```

## Arguments

### *string-expression1* , *string-expression2*

The two VARCHAR expressions to encode and compare.

## Examples

Find how well the Soundex encodings of two strings match:

- Compare the Soundex encodings of **Lewis** and **Li** :

```
> SELECT SOUNDEX_MATCHES('Lewis', 'Li');
SOUNDEX_MATCHES

 3
(1 row)
```

- Compare the Soundex encodings of **Lee** and **Li** :

```
=> SELECT SOUNDEX_MATCHES('Lee', 'Li');
SOUNDEX_MATCHES

 4
(1 row)
```

Find last names in the **employee\_dimension** table whose Soundex encodings match at least 3 characters in the encoding for **Lewis** :

```
=> SELECT DISTINCT(employee_last_name)
 FROM public.employee_dimension
 WHERE SOUNDEX_MATCHES (employee_last_name, 'Lewis') >= 3 ORDER BY employee_last_name;
employee_last_name

Lea
Lee
Leigh
Lewis
Li
Reyes
(6 rows)
```

See also

[SOUNDEX](#)

[SPACE](#)

Returns the specified number of blank spaces, typically for insertion into a character string.

Behavior type

[Immutable](#)

Syntax

```
SPACE(n)
```

## Arguments

***n***

An integer argument that specifies how many spaces to insert.

## Examples

The following example concatenates strings **x** and **y** with 10 spaces inserted between them:

```
=> SELECT 'x' || SPACE(10) || 'y' AS Ten_spaces;
Ten_spaces

x y
(1 row)
```

## SPLIT\_PART

Splits string on the delimiter and returns the string at the location of the beginning of the specified field (counting from 1).

Behavior type

[Immutable](#)

Syntax

```
SPLIT_PART (string , delimiter , field)
```

Arguments

**string**

Argument string

**delimiter**

Delimiter

**field**

(INTEGER) Number of the part to return

Notes

Use this with the character form of the subfield.

Examples

The specified integer of 2 returns the second string, or **def** .

```
=> SELECT SPLIT_PART('abc~@~def~@~ghi', '~@~', 2);
SPLIT_PART

def
(1 row)
```

In the next example, specify 3, which returns the third string, or **789** .

```
=> SELECT SPLIT_PART('123~|~456~|~789', '~|~', 3);
SPLIT_PART

789
(1 row)
```

The tildes are for readability only. Omitting them returns the same results:

```
=> SELECT SPLIT_PART('123|456|789', '|', 3);
SPLIT_PART

789
(1 row)
```

See what happens if you specify an integer that exceeds the number of strings: The result is not null, it is an empty string.

```
=> SELECT SPLIT_PART('123|456|789', '|', 4);
SPLIT_PART

(1 row)

=> SELECT SPLIT_PART('123|456|789', '|', 4) IS NULL;
?column?

f
(1 row)
```

If SPLIT\_PART had returned NULL, LENGTH would have returned 0.

```
=> SELECT LENGTH (SPLIT_PART('123|456|789', '|', 4));
LENGTH

0
(1 row)
```

If the locale of your database is BINARY, SPLIT\_PART calls SPLIT\_PARTB:

```
=> SHOW LOCALE;
name | setting
-----+-----
locale | en_US@collation=binary (LEN_KBINARY)
(1 row)
=> SELECT SPLIT_PART('123456789', '5', 1);
split_partb

1234
(1 row)

=> SET LOCALE TO 'en_US@collation=standard';
INFO 2567: Canonical locale: 'en_US@collation=standard'
Standard collation: 'LEN'
English (United States, collation=standard)
SET

=> SELECT SPLIT_PART('123456789', '5', 1);
split_part

1234
(1 row)
```

See also

- [SPLIT\\_PARTB](#)

## SPLIT\_PARTB

Divides an input string on a delimiter character and returns the Nth segment, counting from 1. The VARCHAR arguments are treated as octets rather than UTF-8 characters.

Behavior type

[Immutable](#)

Syntax

```
SPLIT_PARTB (string, delimiter, part-number)
```

Arguments

### **string**

VARCHAR, the string to split.

### **delimiter**

VARCHAR, the delimiter between segments.

### **part-number**

INTEGER, the part number to return. The first part is 1, not 0.

Examples

The following example returns the third part of its input:

```
=> SELECT SPLIT_PARTB('straße~@~café~@~soupçon', '~@~', 3);
SPLIT_PARTB

soupçon
(1 row)
```

The tildes are for readability only. Omitting them returns the same results:

```
=> SELECT SPLIT_PARTB('straße @ café @ soupçon', '@', 3);
SPLIT_PARTB

soupçon
(1 row)
```

If the requested part number is greater than the number of parts, the function returns an empty string:

```
=> SELECT SPLIT_PARTB('straße @ café @ soupçon', '@', 4);
SPLIT_PARTB

(1 row)

=> SELECT SPLIT_PARTB('straße @ café @ soupçon', '@', 4) IS NULL;
?column?

f
(1 row)
```

If the locale of your database is BINARY, SPLIT\_PART calls SPLIT\_PARTB:

```
=> SHOW LOCALE;
name | setting
-----+-----
locale | en_US@collation=binary (LEN_KBINARY)
(1 row)

=> SELECT SPLIT_PART('123456789', '5', 1);
split_partb

1234
(1 row)

=> SET LOCALE TO 'en_US@collation=standard';
INFO 2567: Canonical locale: 'en_US@collation=standard'
Standard collation: 'LEN'
English (United States, collation=standard)
SET

=> SELECT SPLIT_PART('123456789', '5', 1);
split_part

1234
(1 row)
```

See also

- [SPLIT\\_PART](#)

## STRPOS

Returns an INTEGER value that represents the location of a specified substring within a string (counting from one). If the substring is not found, STRPOS returns 0.

STRPOS is similar to [POSITION](#); however, POSITION allows finding by characters and by octet.

Behavior type

[Immutable](#)

Syntax

```
STRPOS (string-expression , substring)
```

Arguments

### ***string-expression***

The string in which to locate *substring*

### ***substring***

The substring to locate in *string-expression*

Examples

```
=> SELECT ship_type, shipping_key, strpos (ship_type, 'DAY') FROM shipping_dimension WHERE strpos > 0 ORDER BY ship_type, shipping_key;
```

ship_type	shipping_key	strpos
-----------	--------------	--------

ship_type	shipping_key	strpos
NEXT DAY	1	6
NEXT DAY	13	6
NEXT DAY	19	6
NEXT DAY	22	6
NEXT DAY	26	6
NEXT DAY	30	6
NEXT DAY	34	6
NEXT DAY	38	6
NEXT DAY	45	6
NEXT DAY	51	6
NEXT DAY	67	6
NEXT DAY	69	6
NEXT DAY	80	6
NEXT DAY	90	6
NEXT DAY	96	6
NEXT DAY	98	6
TWO DAY	9	5
TWO DAY	21	5
TWO DAY	28	5
TWO DAY	32	5
TWO DAY	40	5
TWO DAY	43	5
TWO DAY	49	5
TWO DAY	50	5
TWO DAY	52	5
TWO DAY	53	5
TWO DAY	61	5
TWO DAY	73	5
TWO DAY	81	5
TWO DAY	83	5
TWO DAY	84	5
TWO DAY	85	5
TWO DAY	94	5
TWO DAY	100	5

(34 rows)

## STRPOSB

Returns an INTEGER value representing the location of a specified substring within a string, counting from one, where each octet in the string is counted (as opposed to characters).

Behavior type

[Immutable](#)

Syntax

```
STRPOSB (string , substring)
```

Arguments

### **string**

(CHAR or VARCHAR) is the string in which to locate the substring

### **substring**

(CHAR or VARCHAR) is the substring to locate

Notes

STRPOSB is identical to [POSITIONB](#) except for the order of the arguments.

Examples

```
=> SELECT STRPOSB('straße', 'e');
```

```
STRPOSB
```

```

7
(1 row)
```

```
=> SELECT STRPOSB('étudiant', 'tud');
```

```
STRPOSB
```

```

3
(1 row)
```

## SUBSTR

Returns VARCHAR or VARBINARY value representing a substring of a specified string.

Behavior type

[Immutable](#)

Syntax

```
SUBSTR (string , position [, extent])
```

Arguments

### **string**

(CHAR/VARCHAR or BINARY/VARBINARY) is the string from which to extract a substring. If null, Vertica returns no results.

### **position**

(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one by characters). If 0 or negative, Vertica returns no results.

### **extent**

(INTEGER or DOUBLE PRECISION) is the length of the substring to extract (in characters). The default is the end of the string.

Notes

SUBSTR truncates DOUBLE PRECISION input values.

Examples

```
=> SELECT SUBSTR('abc'::binary(3),1);
```

```
substr
```

```

abc
(1 row)
```

```
=> SELECT SUBSTR('123456789', 3, 2);
```

```
substr
```

```

34
(1 row)
```

```
=> SELECT SUBSTR('123456789', 3);
```

```
substr
```

```

3456789
(1 row)
```

```
=> SELECT SUBSTR(TO_BITSTRING(HEX_TO_BINARY('0x10')), 2, 2);
```

```
substr
```

```

00
(1 row)
```

```
=> SELECT SUBSTR(TO_HEX(10010), 2, 2);
```

```
substr
```

```

71
(1 row)
```

## SUBSTRB

Returns an octet value representing the substring of a specified string.

Behavior type

[Immutable](#)

Syntax

```
SUBSTRB (string , position [, extent])
```

Arguments

### **string**

(CHAR/VARCHAR) is the string from which to extract a substring.

### **position**

(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one in octets).

### **extent**

(INTEGER or DOUBLE PRECISION) is the length of the substring to extract (in octets). The default is the end of the string

Notes

- This function treats the multibyte character string as a string of octets (bytes) and uses octet numbers as incoming and outgoing position specifiers and lengths. The strings themselves are type VARCHAR, but they treated as if each octet were a separate character.
- SUBSTRB truncates DOUBLE PRECISION input values.

Examples

```
=> SELECT SUBSTRB('soupçon', 5);
SUBSTRB
```

```

çon
(1 row)
```

```
=> SELECT SUBSTRB('soupçon', 5, 2);
SUBSTRB
```

```

ç
(1 row)
```

Vertica returns the following error message if you use BINARY/VARBINARY:

```
=>SELECT SUBSTRB('abc'::binary(3),1);
ERROR: function substrb(binary, int) does not exist, or permission is denied for substrb(binary, int)
HINT: No function matches the given name and argument types. You may need to add explicit type casts.
```

## SUBSTRING

Returns a value representing a substring of the specified string at the given position, given a value, a position, and an optional length. SUBSTRING truncates DOUBLE PRECISION input values.

### Behavior type

[Immutable](#) if USING OCTETS, [stable](#) otherwise.

### Syntax

```
SUBSTRING (string, position[, length]
 [USING {CHARACTERS | OCTETS }])
SUBSTRING (string FROM position [FOR length]
 [USING { CHARACTERS | OCTETS }])
```

### Arguments

#### *string*

(CHAR/VARCHAR or BINARY/VARBINARY) is the string from which to extract a substring

#### *position*

(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one by either characters or octets). (The default is characters.) If position is greater than the length of the given value, an empty value is returned.

#### *length*

(INTEGER or DOUBLE PRECISION) is the length of the substring to extract in either characters or octets. (The default is characters.) The default is the end of the string. If a length is given the result is at most that many bytes. The maximum length is the length of the given value less the given position. If no length is given or if the given length is greater than the maximum length then the length is set to the maximum length.

### USING CHARACTERS | OCTETS

Determines whether the value is expressed in characters (the default) or octets.

### Examples

```
=> SELECT SUBSTRING('abc'::binary(3),1);
```

```
substring
```

```

abc
```

```
(1 row)
```

```
=> SELECT SUBSTRING('soupçon', 5, 2 USING CHARACTERS);
```

```
substring
```

```

çø
```

```
(1 row)
```

```
=> SELECT SUBSTRING('soupçon', 5, 2 USING OCTETS);
```

```
substring
```

```

ç
```

```
(1 row)
```

If you use a negative position, then the functions starts at a non-existent position. In this example, that means counting eight characters starting at position -4. So the function starts at the empty position -4 and counts five characters, including a position for zero which is also empty. This returns three characters.

```
=> SELECT SUBSTRING('1234567890', -4, 8);
```

```
substring
```

```

123
```

```
(1 row)
```

## TRANSLATE

Replaces individual characters in *string\_to\_replace* with other characters.

Behavior type

[Immutable](#)

Syntax

```
TRANSLATE (string_to_replace , from_string , to_string);
```

Arguments

### **string\_to\_replace**

String to be translated.

### **from\_string**

Contains characters that should be replaced in *string\_to\_replace*.

### **to\_string**

Any character in *string\_to\_replace* that matches a character in *from\_string* is replaced by the corresponding character in *to\_string*.

Examples

```
=> SELECT TRANSLATE('straße', 'ß', 'ss');
```

```
TRANSLATE
```

```

strase
```

```
(1 row)
```

## TRIM

Combines the BTRIM, LTRIM, and RTRIM functions into a single function.

Behavior type

[Immutable](#)

Syntax

```
TRIM ([[LEADING | TRAILING | BOTH] [characters] FROM] expression)
```

Arguments

### LEADING

Removes the specified characters from the left side of the string

### TRAILING

Removes the specified characters from the right side of the string

### BOTH

Removes the specified characters from both sides of the string (default)

### characters

(CHAR or VARCHAR) specifies the characters to remove from *expression*. The default is the space character.

### expression

(CHAR or VARCHAR) is the string to trim

Examples

```
=> SELECT '-' || TRIM(LEADING 'x' FROM 'xxdatabasexx') || '-';
?column?

-xdatabasexx-
(1 row)

=> SELECT '-' || TRIM(TRAILING 'x' FROM 'xxdatabasexx') || '-';
?column?

-xxdatabase-
(1 row)

=> SELECT '-' || TRIM(BOTH 'x' FROM 'xxdatabasexx') || '-';
?column?

-database-
(1 row)

=> SELECT '-' || TRIM('x' FROM 'xxdatabasexx') || '-';
?column?

-database-
(1 row)

=> SELECT '-' || TRIM(LEADING FROM ' database ') || '-';
?column?

-database -
(1 row)

=> SELECT '-' || TRIM(' database ') || '-'; ?column?

-database-
(1 row)
```

See also

- [BTRIM](#)
- [LTRIM](#)
- [RTRIM](#)

UPPER

Returns a VARCHAR value containing the argument converted to uppercase letters.

Starting in Release 5.1, this function treats the *string* argument as a UTF-8 encoded string, rather than depending on the collation setting of the locale (for example, collation=binary) to identify the encoding.

Behavior type

[stable](#)

Syntax

```
UPPER (expression)
```

Arguments

***expression***

CHAR or VARCHAR containing the string to convert

Notes

UPPER is restricted to 32500 octet inputs, since it is possible for the UTF-8 representation of result to double in size.

Examples

```
=> SELECT UPPER('AbCdEfG');
 UPPER

ABCDEFG
(1 row)
=> SELECT UPPER('étudiant');
 UPPER

ÉTUDIANT
(1 row)
```

UPPERB

Returns a character string with each ASCII character converted to uppercase. Multibyte characters are not converted and are skipped.

Behavior type

[Immutable](#)

Syntax

```
UPPERB (expression)
```

Arguments

***expression***

(CHAR or VARCHAR) is the string to convert

Examples

In the following example, the multibyte UTF-8 character é is not converted to uppercase:

```
=> SELECT UPPERB('étudiant');
 UPPERB

éTUDIANT
(1 row)
=> SELECT UPPERB('AbCdEfG');
 UPPERB

ABCDEFG
(1 row)
=> SELECT UPPERB('The Vertica Database');
 UPPERB

THE VERTICA DATABASE
(1 row)
```

URI functions

The functions in this section follow the RFC 3986 standard for percent-encoding a Universal Resource Identifier (URI).

In this section

- [URI\\_PERCENT\\_DECODE](#)
- [URI\\_PERCENT\\_ENCODE](#)

## URI\_PERCENT\_DECODE

Decodes a percent-encoded Universal Resource Identifier (URI) according to the RFC 3986 standard.

Syntax

```
URI_PERCENT_DECODE (expression)
```

Behavior type

[Immutable](#)

Parameters

**expression**

(VARCHAR) is the string to convert.

Examples

The following example invokes `uri_percent_decode` on the Websites column of the URI table and returns a decoded URI:

```
=> SELECT URI_PERCENT_DECODE(Websites) from URI;
 URI_PERCENT_DECODE
```

```

http://www.faqs.org/rfcs/rfc3986.html x xj%a%
```

```
(1 row)
```

The following example returns the original URI in the Websites column and its decoded version:

```
=> SELECT Websites, URI_PERCENT_DECODE (Websites) from URI;
```

```
 Websites | URI_PERCENT_DECODE
```

```
-----+-----
http://www.faqs.org/rfcs/rfc3986.html+x%20x%6a%a% | http://www.faqs.org/rfcs/rfc3986.html x xj%a%
```

```
(1 row)
```

## URI\_PERCENT\_ENCODE

Encodes a Universal Resource Identifier (URI) according to the RFC 3986 standard for percent encoding. For compatibility with older encoders, this function converts `+` to space; space is converted to `%20`.

Syntax

```
URI_PERCENT_ENCODE (expression)
```

Behavior type

[Immutable](#)

Parameters

**expression**

(VARCHAR) is the string to convert.

Examples

The following example shows how the `uri_percent_encode` function is invoked on a the Websites column of the URI table and returns an encoded URI:

```
=> SELECT URI_PERCENT_ENCODE(Websites) from URI;
 URI_PERCENT_ENCODE
```

```

http%3A%2F%2Fexample.com%2F%3F%3D11%2F15
```

```
(1 row)
```

The following example returns the original URI in the Websites column and it's encoded form:

```
=> SELECT Websites, URI_PERCENT_ENCODE(Websites) from URI; Websites | URI_PERCENT_ENCODE
-----+-----
http://example.com/?=11/15 | http%3A%2F%2Fexample.com%2F%3F%3D11%2F15
(1 row)
```

## UUID functions

Currently, Vertica provides one function to support [UUID](#) data types, [UUID\\_GENERATE](#).

In this section

- [UUID\\_GENERATE](#)

### UUID\_GENERATE

Returns a new universally unique identifier ( [UUID](#) ) that is generated based on high-quality randomness from [/dev/urandom](#) .

Behavior type

[Volatile](#)

Syntax

```
UUID_GENERATE()
```

### Examples

```
=> CREATE TABLE Customers(
 cust_id UUID DEFAULT UUID_GENERATE(),
 lname VARCHAR(36),
 fname VARCHAR(24));
CREATE TABLE
=> INSERT INTO Customers VALUES (DEFAULT, 'Kearney', 'Thomas');
OUTPUT

 1
(1 row)

=> COPY Customers (lname, fname) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Pham|Duc
>> Garcia|Mary
>> \.
=> SELECT * FROM Customers;
 cust_id | lname | fname
-----+-----
03fe0794-ac5d-42d4-8246-54f7ec81ed0c | Pham | Duc
6950313d-c77e-4c11-a86e-0a54aa3ec114 | Kearney | Thomas
9c9653ce-c2e4-4441-b0f7-0137b54cc28c | Garcia | Mary
(3 rows)
```

## Database Designer functions

Database Designer functions perform the following operations, generally performed in the following order:

1. [Create a design](#) .
2. [Set design properties](#) .
3. [Populate a design](#) .
4. [Create design and deployment scripts](#) .
5. [Get design data](#) .
6. [Clean up](#) .

### Important

You can also use meta-function [DESIGNER\\_SINGLE\\_RUN](#) , which encapsulates all of these steps with a single call. The meta-function iterates over all queries within a specified timespan, and returns with a design ready for deployment.

For detailed information, see [Workflow for running Database Designer programmatically](#). For information on required privileges, see [Privileges for running Database Designer functions](#)

### Caution

Before running Database Designer functions on an existing schema, back up the current design by calling [EXPORT\\_CATALOG](#).

Create a design

[DESIGNER\\_CREATE\\_DESIGN](#) directs Database Designer to create a design.

Set design properties

The following functions let you specify design properties:

- [DESIGNER\\_SET\\_DESIGN\\_TYPE](#): Specifies whether the design is comprehensive or incremental.
- [DESIGNER\\_DESIGN\\_PROJECTION\\_ENCODINGS](#): Analyzes encoding in the specified projections and creates a script that implements encoding recommendations.
- [DESIGNER\\_SET\\_DESIGN\\_KSAFETY](#): Sets the [K-safety](#) value for a comprehensive design.
- [DESIGNER\\_SET\\_OPTIMIZATION\\_OBJECTIVE](#): Specifies whether the design optimizes for query or load performance.
- [DESIGNER\\_SET\\_PROPOSE\\_UNSEGMENTED\\_PROJECTIONS](#): Enables inclusion of unsegmented projections in the design.

Populate a design

The following functions let you add tables and queries to your Database Designer design:

- [DESIGNER\\_ADD\\_DESIGN\\_TABLES](#): Adds the specified tables to a design.
- [DESIGNER\\_ADD\\_DESIGN\\_QUERY](#), [DESIGNER\\_ADD\\_DESIGN\\_QUERIES](#), [DESIGNER\\_ADD\\_DESIGN\\_QUERIES\\_FROM\\_RESULTS](#): Adds queries to the design and weights them.

Create design and deployment scripts

The following functions populate the Database Designer workspace and create design and deployment scripts. You can also analyze statistics, deploy the design automatically, and drop the workspace after the deployment:

- [DESIGNER\\_RUN\\_POPULATE\\_DESIGN\\_AND\\_DEPLOY](#): Populates the design and creates design and deployment scripts.
- [DESIGNER\\_WAIT\\_FOR\\_DESIGN](#): Waits for a currently running design to complete.

Reset a design

[DESIGNER\\_RESET\\_DESIGN](#) discards all the run-specific information of the previous Database Designer build or deployment of the specified design but retains its configuration.

Get design data

The following functions display information about projections and scripts that the Database Designer created:

- [DESIGNER\\_OUTPUT\\_ALL\\_DESIGN\\_PROJECTIONS](#): Sends to standard output DDL statements that define design projections.
- [DESIGNER\\_OUTPUT\\_DEPLOYMENT\\_SCRIPT](#): Sends to standard output a design's deployment script.

Cleanup

The following functions cancel any running Database Designer operation or drop a Database Designer design and all its contents:

- [DESIGNER\\_CANCEL\\_POPULATE\\_DESIGN](#): Cancels population or deployment operation for the specified design if it is currently running.
- [DESIGNER\\_DROP\\_DESIGN](#): Removes the schema associated with the specified design and all its contents.
- [DESIGNER\\_DROP\\_ALL\\_DESIGNS](#): Removes all Database Designer-related schemas associated with the current user.

In this section

- [DESIGNER\\_ADD\\_DESIGN\\_QUERIES](#)
- [DESIGNER\\_ADD\\_DESIGN\\_QUERIES\\_FROM\\_RESULTS](#)
- [DESIGNER\\_ADD\\_DESIGN\\_QUERY](#)
- [DESIGNER\\_ADD\\_DESIGN\\_TABLES](#)
- [DESIGNER\\_CANCEL\\_POPULATE\\_DESIGN](#)
- [DESIGNER\\_CREATE\\_DESIGN](#)
- [DESIGNER\\_DESIGN\\_PROJECTION\\_ENCODINGS](#)
- [DESIGNER\\_DROP\\_ALL\\_DESIGNS](#)
- [DESIGNER\\_DROP\\_DESIGN](#)
- [DESIGNER\\_OUTPUT\\_ALL\\_DESIGN\\_PROJECTIONS](#)
- [DESIGNER\\_OUTPUT\\_DEPLOYMENT\\_SCRIPT](#)

- [DESIGNER\\_RESET\\_DESIGN](#)
- [DESIGNER\\_RUN\\_POPULATE\\_DESIGN\\_AND\\_DEPLOY](#)
- [DESIGNER\\_SET\\_DESIGN\\_KSAFETY](#)
- [DESIGNER\\_SET\\_DESIGN\\_TYPE](#)
- [DESIGNER\\_SET\\_OPTIMIZATION\\_OBJECTIVE](#)
- [DESIGNER\\_SET\\_PROPOSE\\_UNSEGMENTED\\_PROJECTIONS](#)
- [DESIGNER\\_SINGLE\\_RUN](#)
- [DESIGNER\\_WAIT\\_FOR\\_DESIGN](#)

## DESIGNER\_ADD\_DESIGN\_QUERIES

Reads and evaluates queries from an input file, and adds the queries that it accepts to the specified design. All accepted queries are assigned a weight of 1.

The following requirements apply:

- All queried tables must previously be added to the design with [DESIGNER\\_ADD\\_DESIGN\\_TABLES](#).
- If the [design\\_type](#) is incremental, the Database Designer reads only the first 100 queries in the input file, and ignores all queries beyond that number.

All accepted queries are added to the system table [DESIGN\\_QUERIES](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_QUERIES ('design-name', 'queries-file' [, return-results])
```

Parameters

### **design-name**

Name of the target design.

### **queries-file**

Absolute path and name of the file that contains the queries to evaluate, on the local file system of the node where the session is connected, or [another file system or object store](#) that Vertica supports.

### **return-results**

Boolean, optionally specifies whether to return results of the add operation to standard output. If set to true, Database Designer returns the following results:

- Number of accepted queries
- Number of queries referencing non-design tables
- Number of unsupported queries
- Number of illegal queries

Privileges

Non-superuser: design creator with all privileges required to execute the queries in *input-file*.

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
  - External or system tables only
  - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example adds queries from [vmart\\_queries.sql](#) to the [VMART\\_DESIGN](#) design. This file contains nine queries. The statement includes a third argument of true, so Database Designer returns results of the add operation:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES ('VMART_DESIGN', '/tmp/examples/vmart_queries.sql', 'true');
...
DESIGNER_ADD_DESIGN_QUERIES

Number of accepted queries =9
Number of queries referencing non-design tables =0
Number of unsupported queries =0
Number of illegal queries =0
(1 row)
```

See also

[Running Database Designer programmatically](#)

DESIGNER\_ADD\_DESIGN\_QUERIES\_FROM\_RESULTS

Executes the specified query and evaluates results in the following columns:

- **QUERY\_TEXT** (required): Text of potential design queries.
- **QUERY\_WEIGHT** (optional): The weight assigned to each query that indicates its importance relative to other queries, a real number  $>0$  and  $\leq 1$ . Database Designer uses this setting when creating the design to prioritize the query. If **DESIGNER\_ADD\_DESIGN\_QUERIES\_FROM\_RESULTS** returns any results that omit this value, Database Designer sets their weight to 1.

After evaluating the queries in **QUERY\_TEXT**, **DESIGNER\_ADD\_DESIGN\_QUERIES\_FROM\_RESULTS** adds all accepted queries to the design. An unlimited number of queries can be added to the design.

Before you add queries to a design, you must add the queried tables with [DESIGNER\\_ADD\\_DESIGN\\_TABLES](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS ('design-name', 'query')
```

Parameters

**design-name**

Name of the target design.

**query**

A valid SQL query whose results contain columns named **QUERY\_TEXT** and, optionally, **QUERY\_WEIGHT**.

Privileges

Non-superuser: design creator with all privileges required to execute the specified query, and all queries returned by this function

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
  - External or system tables only
  - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example queries the system table [QUERY\\_REQUESTS](#) for all long-running queries ( $> 1$  million microseconds) and adds them to the **VMART\_DESIGN** design. The query returns no information on query weights, so all queries are assigned a weight of 1:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS ('VMART_DESIGN',
'SELECT request as query_text FROM query_requests where request_duration_ms > 1000000 AND request_type =
"QUERY";');
```

See also

[Running Database Designer programmatically](#)

DESIGNER\_ADD\_DESIGN\_QUERY

Reads and parses the specified query, and if accepted, adds it to the design. Before you add queries to a design, you must add the queried tables with [DESIGNER\\_ADD\\_DESIGN\\_TABLES](#).

All accepted queries are added to the system table [DESIGN\\_QUERIES](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_QUERY ('design-name', 'design-query' [, query-weight])
```

Parameters

***design-name***

Name of the target design.

***design-query***

Executable SQL query.

***query-weight***

Optionally assigns a weight to each query that indicates its importance relative to other queries, a real number  $>0$  and  $\leq 1$ . Database Designer uses this setting to prioritize queries in the design .

If you omit this parameter, Database Designer assigns a weight of 1.

Privileges

Non-superuser: design creator with all privileges required to execute the specified query

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
  - External or system tables only
  - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example adds the specified query to the **VMART\_DESIGN** design and assigns that query a weight of 0.5:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERY (
 'VMART_DESIGN',
 'SELECT customer_name, customer_type FROM customer_dimension ORDER BY customer_name ASC;', 0.5
);
```

See also

[Running Database Designer programmatically](#)

[DESIGNER\\_ADD\\_DESIGN\\_TABLES](#)

Adds the specified tables to a design. You must run [DESIGNER\\_ADD\\_DESIGN\\_TABLES](#) before adding design queries to the design. If no tables are added to the design, Vertica does not accept design queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_ADD_DESIGN_TABLES ('design-name', ['table-spec[...]'] [, 'analyze-statistics'])
```

Parameters

***design-name***

Name of the Database Designer design.

***table-spec* [...]**

One or more comma-delimited arguments that specify which tables to add to the design, where each *table-spec* argument can specify tables as follows:

- `[ schema .] table`  
Add *table* to the design.
- `schema .*`  
Add all tables in *schema* .

If set to an empty string, Vertica adds all tables in the database to which the user has access.

### **analyze-statistics**

Boolean that optionally specifies whether to run `ANALYZE_STATISTICS` after adding the specified tables to the design, by default set to `false` .

Accurate statistics help Database Designer optimize compression and query performance. Updating statistics takes time and resources.

### Privileges

Non-superuser: design creator with USAGE privilege on the design table schema and owner of the design table

### Examples

The following example adds to design `VMART_DESIGN` all tables from schemas `online_sales` and `store` , and analyzes statistics for those tables:

```
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN', 'online_sales.*', 'store.*', 'true');
DESIGNER_ADD_DESIGN_TABLES

 7
(1 row)
```

See also

[Running Database Designer programmatically](#)

`DESIGNER_CANCEL_POPULATE_DESIGN`

Cancels population or deployment operation for the specified design if it is currently running. When you cancel a deployment, the Database Designer cancels the projection refresh operation. It does not roll back projections that it already deployed and refreshed.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

### Behavior type

[Volatile](#)

### Syntax

```
DESIGNER_CANCEL_POPULATE_DESIGN ('design-name')
```

### Parameters

***design-name***

Name of the design operation to cancel.

### Privileges

Non-superuser: design creator

### Examples

The following example cancels a currently running design for `VMART_DESIGN` and then drops the design:

```
=> SELECT DESIGNER_CANCEL_POPULATE_DESIGN ('VMART_DESIGN');
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN', 'true');
```

See also

[Running Database Designer programmatically](#)

`DESIGNER_CREATE_DESIGN`

Creates a design with the specified name.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

### Behavior type

[Volatile](#)

### Syntax

```
DESIGNER_CREATE_DESIGN ('design-name')
```

### Parameters

## design-name

Name of the design to create, can contain only alphanumeric and underscore ( \_ ) characters.

Two users cannot have designs with the same name at the same time.

## Privileges

- Superuser
- DBDUSER with WRITE privileges on storage location of *design-name* .

## Database Designer system views

If any of the following [V\\_MONITOR](#) tables do not already exist from previous designs, [DESIGNER\\_CREATE\\_DESIGN](#) creates them:

- [DESIGNS](#)
- [DESIGN\\_TABLES](#)
- [DEPLOYMENT\\_PROJECTIONS](#)
- [DEPLOYMENT\\_PROJECTION\\_STATEMENTS](#)
- [DESIGN\\_QUERIES](#)
- [OUTPUT\\_DEPLOYMENT\\_STATUS](#)
- [OUTPUT\\_EVENT\\_HISTORY](#)

## Examples

The following example creates the design **VMART\_DESIGN** :

```
=> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');
DESIGNER_CREATE_DESIGN

0
(1 row)
```

## See also

[Running Database Designer programmatically](#)

[DESIGNER\\_DESIGN\\_PROJECTION\\_ENCODINGS](#)

Analyzes encoding in the specified projections, creates a script to implement encoding recommendations, and optionally deploys the recommendations.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

## Behavior type

[Volatile](#)

## Syntax

```
DESIGNER_DESIGN_PROJECTION_ENCODINGS ('[proj-spec[,...]]', '[destination]' [, 'deploy'] [, 'reanalyze-encodings'])
```

## Parameters

### *proj-spec* [...]

One or more comma-delimited projections to add to the design. Each projection can be specified in one of the following ways:

- `[[ schema .] table .] projection`  
Specifies to analyze *projection* .
- `schema .*`  
Specifies to analyze all projections in the named schema.
- `[ schema .] table`  
Specifies to analyze all projections of the named table.

If set to an empty string, Vertica analyzes all projections in the database to which the user has access.

For example, the following statement specifies to analyze all projections in schema `private` , and send the results to the file `encodings.sql` :

```
=> SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('mydb.private.*','encodings.sql');
```

## *destination*

Specifies where to send output, one of the following:

- Empty string ( " ) writes the script to standard output.
- Pathname of a SQL output file. If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.

### *deploy*

Boolean that specifies whether to deploy encoding changes.

**Default:** false

### *reanalyze-encodings*

Boolean that specifies whether `DESIGNER_DESIGN_PROJECTION_ENCODINGS` analyzes encodings in a projection where all columns are already encoded:

- **false** : Analyzes no columns and generates no recommendations if all columns are encoded.
- **true** : Ignores existing encodings and generates recommendations.

**Default:** false

### Privileges

Superuser, or DBDUSER with the following privileges:

- OWNER of all projections to analyze
- USAGE privilege on the schema for the specified projections

### Examples

The following example requests that Database Designer analyze encodings of the table `online_sales.call_center_dimension` :

- The second parameter *destination* is set to an empty string, so the script is sent to standard output (shown truncated below).
- The last two parameters *deploy* and *reanalyze-encodings* are omitted, so Database Designer does not execute the script or reanalyze existing encodings:

```
=> SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('online_sales.call_center_dimension');
```

## DESIGNER\_DESIGN\_PROJECTION\_ENCODINGS

[Running Database Designer programmatically](#)

DESIGNER\_DROP\_ALL\_DESIGNS

Removes all Database Designer-related schemas associated with the current user. Use this function to remove database objects after one or more Database Designer sessions complete execution.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_DROP_ALL_DESIGNS()
```

Parameters

None.

## Privileges

Non-superuser: design creator

## Examples

The following example removes all schema and their contents associated with the current user. `DESIGNER_DROP_ALL_DESIGNS` returns the number of designs dropped:

```
=> SELECT DESIGNER_DROP_ALL_DESIGNS();
DESIGNER_DROP_ALL_DESIGNS

 2
(1 row)
```

See also

- [DESIGNER\\_CANCEL\\_POPULATE\\_DESIGN](#)
- [DESIGNER\\_DROP\\_DESIGN](#)

## DESIGNER\_DROP\_DESIGN

Removes the schema associated with the specified design and all its contents. Use `DESIGNER_DROP_DESIGN` after a Database Designer design or deployment completes successfully. You must also use it to drop a design before creating another one under the same name.

To drop all designs that you created, use [DESIGNER\\_DROP\\_ALL\\_DESIGNS](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_DROP_DESIGN ('design-name' [, force-drop])
```

Parameters

### ***design-name***

Name of the design to drop.

### ***force-drop***

Boolean that overrides any dependencies that otherwise prevent Vertica from executing this function—for example, the design is in use or is currently being deployed. If you omit this parameter, Vertica sets it to `false`.

## Privileges

Non-superuser: design creator

## Examples

The following example deletes the Database Designer design `VMART_DESIGN` and all its contents:

```
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN');
```

See also

[Running Database Designer programmatically](#)

## DESIGNER\_OUTPUT\_ALL\_DESIGN\_PROJECTIONS

Displays the DDL statements that define the design projections to standard output.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS ('design-name')
```

Parameters

### ***design-name***

Name of the target design.

## Privileges

Superuser or DBUSER

## Examples

The following example returns the design projection DDL statements for `vmart_design` :

```
=> SELECT DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS('vmart_design');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
(
customer_key ENCODING DELTAVAL,
customer_type ENCODING AUTO,
customer_name ENCODING AUTO,

customer_since ENCODING DELTAVAL,
deal_stage ENCODING AUTO,
deal_size ENCODING DELTARANGE_COMP,
last_deal_update ENCODING DELTARANGE_COMP
)
AS
SELECT customer_key,
 customer_type,
 customer_name,
 customer_gender,
 title,
 household_id,
 customer_address,
 customer_city,
 customer_state,
 customer_region,
 marital_status,
 customer_age,
 number_of_children,
 annual_income,
 occupation,
 largest_bill_amount,
 store_membership_card,
 customer_since,
 deal_stage,
 deal_size,
 last_deal_update
FROM public.customer_dimension
ORDER BY customer_gender,
 annual_income
UNSEGMENTED ALL NODES;
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/
(
...
```

See also

[DESIGNER\\_OUTPUT\\_DEPLOYMENT\\_SCRIPT](#)

DESIGNER\_OUTPUT\_DEPLOYMENT\_SCRIPT

Displays the deployment script for the specified design to standard output. If the design is already deployed, Vertica ignores this function.

To output only the **CREATE PROJECTION** commands in a design script, use [DESIGNER\\_OUTPUT\\_ALL\\_DESIGN\\_PROJECTIONS](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT ('design-name')
```

Parameters

**design-name**

Name of the target design.

Privileges

Non-superuser: design creator

Examples

The following example displays the deployment script for **VMART\_DESIGN** :

```
=> SELECT DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT('VMART_DESIGN');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
...
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/
...
select refresh('public.customer_dimension,
 public.product_dimension,
 public.promotion.dimension,
 public.date_dimension');
select make_ahm_now();
DROP PROJECTION public.customer_dimension_super CASCADE;
DROP PROJECTION public.product_dimension_super CASCADE;
...
```

See also

[DESIGNER\\_OUTPUT\\_ALL\\_DESIGN\\_PROJECTIONS](#)

[DESIGNER\\_RESET\\_DESIGN](#)

Discards all run-specific information of the previous Database Designer build or deployment of the specified design but keeps its configuration. You can make changes to the design as needed, for example, by changing parameters or adding additional tables and/or queries, before running the design again.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_RESET_DESIGN ('design-name')
```

Parameters

**design-name**

Name of the design to reset.

Privileges

Non-superuser: design creator

Examples

The following example resets the Database Designer design VMART\_DESIGN:

```
=> SELECT DESIGNER_RESET_DESIGN ('VMART_DESIGN');
```

[DESIGNER\\_RUN\\_POPULATE\\_DESIGN\\_AND\\_DEPLOY](#)

Populates the design and creates the design and deployment scripts. [DESIGNER\\_RUN\\_POPULATE\\_DESIGN\\_AND\\_DEPLOY](#) can also analyze statistics, deploy the design, and drop the workspace after the deployment.

The files output by this function have the permissions 666 or rw-rw-rw-, which allows any Linux user on the node to read or write to them. It is highly recommended that you keep the files in a secure directory.

### Caution

DESIGNER\_RUN\_POPULATE\_DESIGN\_AND\_DEPLOY does not create a backup copy of the current design before deploying the new design. Before running this function, back up the existing schema design with [EXPORT\\_CATALOG](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (
 'design-name',
 'output-design-file',
 'output-deployment-file'
 [, 'analyze-statistics']
 [, 'deploy']
 [, 'drop-design-workspace']
 [, 'continue-after-error']
)
```

Parameters

#### **design-name**

Name of the design to populate and deploy.

#### **output-design-filename**

Absolute path and name of the file to contain DDL statements that create design projections, on the local file system of the node where the session is connected, or [another file system or object store](#) that Vertica supports.

#### **output-deployment-filename**

Absolute path and name of the file to contain the deployment script, on the local file system of the node where the session is connected, or [another file system or object store](#) that Vertica supports.

#### **analyze-statistics**

Specifies whether to collect or refresh statistics for the tables before populating the design. If set to true, Vertica Invokes [ANALYZE\\_STATISTICS](#). Accurate statistics help Database Designer optimize compression and query performance. However, updating statistics requires time and resources.

**Default:** false

#### **deploy**

Specifies whether to deploy the Database Designer design using the deployment script created by this function.

**Default:** true

#### **drop-design-workspace**

Specifies whether to drop the design workspace after the design is deployed.

**Default:** true

#### **continue-after-error**

Specifies whether DESIGNER\_RUN\_POPULATE\_DESIGN\_AND\_DEPLOY continues to run after an error occurs. By default, an error causes this function to terminate.

**Default:** false

Privileges

Non-superuser: design creator with WRITE privileges on storage locations of design and deployment scripts

Requirements

Before calling this function, you must:

- Create a design, a logical schema with tables.

- Associate tables with the design.
- Load queries to the design.
- Set design properties (K-safety level, mode, and policy).

## Examples

The following example creates projections for and deploys the **VMART\_DESIGN** design, and analyzes statistics about the design tables.

```
=> SELECT DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (
 'VMART_DESIGN',
 '/tmp/examples/vmart_design_files/design_projections.sql',
 '/tmp/examples/vmart_design_files/design_deploy.sql',
 'true',
 'true',
 'false',
 'false'
);
```

See also

[Running Database Designer programmatically](#)

DESIGNER\_SET\_DESIGN\_KSAFETY

Sets [K-safety](#) for a comprehensive design and stores the K-safety value in the [DESIGNS](#) table. Database Designer ignores this function for incremental designs.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SET_DESIGN_KSAFETY ('design-name' [, k-level])
```

Parameters

### *design-name*

Name of the design for which you want to set the K-safety value, type VARCHAR.

### *k-level*

An integer between 0 and 2 that specifies the level of K-safety for the target design. This value must be compatible with the number of nodes in the database cluster:

- *k-level* = 0 :  $\geq 1$  nodes
- *k-level* = 1 :  $\geq 3$  nodes
- *k-level* = 2 :  $\geq 5$  nodes

If you omit this parameter, Vertica sets K-safety for this design to 0 or 1, according to the number of nodes: 1 if the cluster contains  $\geq 3$  nodes, otherwise 0.

If you are a DBADMIN user and *k-level* differs from system K-safety, Vertica changes system K-safety as follows:

- If *k-level* is less than system K-safety, Vertica changes system K-safety to the lower level after the design is deployed.
- If *k-level* is greater than system K-safety and is valid for the database cluster, Vertica creates the required number of buddy projections for the tables in this design. If the design applies to all database tables, or all tables in the database have the required number of buddy projections, Database Designer changes system K-safety to *k-level*.

If the design excludes some database tables and the number of their buddy projections is less than *k-level*, Database Designer leaves system K-safety unchanged. Instead, it returns a warning and indicates which tables need new buddy projections in order to adjust system K-safety.

If you are a DBDUSER, Vertica ignores this parameter.

Privileges

Non-superuser: design creator

Examples

The following example set K-safety for the VMART\_DESIGN design to 1:

```
=> SELECT DESIGNER_SET_DESIGN_KSAFETY('VMART_DESIGN', 1);
```

See also

## [Running Database Designer programmatically](#)

### DESIGNER\_SET\_DESIGN\_TYPE

Specifies whether Database Designer creates a comprehensive or incremental design. **DESIGNER\_SET\_DESIGN\_TYPE** stores the design mode in the [DESIGNS](#) table.

#### Important

If you do not explicitly set a design mode with this function, Database Designer creates a comprehensive design.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

#### Behavior type

##### [Volatile](#)

#### Syntax

```
DESIGNER_SET_DESIGN_TYPE ('design-name', 'mode')
```

#### Parameters

##### **design-name**

Name of the target design.

##### **mode**

Name of the mode that Database Designer should use when designing the database, one of the following:

- **COMPREHENSIVE** : Creates an initial or replacement design for all tables in the specified schemas. You typically create a comprehensive design for a new database.
- **INCREMENTAL** : Modifies an existing design with additional projection that are optimized for new or modified queries.

#### Note

Incremental designs always inherit the K-safety value of the database.

For more information, see [Design Types](#) .

#### Privileges

Non-superuser: design creator

#### Examples

The following examples show the two design mode options for the **VMART\_DESIGN** design:

```
=> SELECT DESIGNER_SET_DESIGN_TYPE(
 'VMART_DESIGN',
 'COMPREHENSIVE');
DESIGNER_SET_DESIGN_TYPE

 0
(1 row)
=> SELECT DESIGNER_SET_DESIGN_TYPE(
 'VMART_DESIGN',
 'INCREMENTAL');
DESIGNER_SET_DESIGN_TYPE

 0
(1 row)
```

#### See also

## [Running Database Designer programmatically](#)

### DESIGNER\_SET\_OPTIMIZATION\_OBJECTIVE

Valid only for comprehensive database designs, specifies the optimization objective Database Designer uses. Database Designer ignores this function for incremental designs.

**DESIGNER\_SET\_OPTIMIZATION\_OBJECTIVE** stores the optimization objective in the [DESIGNS](#) table.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SET_OPTIMIZATION_OBJECTIVE ('design-name', 'policy')
```

Parameters

**design-name**

Name of the target design.

**policy**

Specifies the design's optimization policy, one of the following:

- **QUERY** : Optimize for query performance. This can result in a larger database storage footprint because additional projections might be created.
- **LOAD** : Optimize for load performance so database size is minimized. This can result in slower query performance.
- **BALANCED** : Balance the design between query performance and database size.

Privileges

Non-superuser: design creator

Examples

The following example sets the optimization objective option for the **VMART\_DESIGN** design: to **QUERY** :

```
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE('VMART_DESIGN', 'QUERY');
DESIGNER_SET_OPTIMIZATION_OBJECTIVE

0
(1 row)
```

See also

[Running Database Designer programmatically](#)

DESIGNER\_SET\_PROPOSE\_UNSEGMENTED\_PROJECTIONS

Specifies whether a design can include [unsegmented projections](#). Vertica ignores this function on a one-node cluster, where all projections must be unsegmented.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS ('design-name', unsegmented)
```

Parameters

**design-name**

Name of the target design.

**unsegmented**

Boolean that specifies whether Database Designer can propose unsegmented projections for tables in this design. When you create a design, the **propose\_unsegmented\_projections** value in system table [DESIGNS](#) for this design is set to true. If

**DESIGNER\_SET\_PROPOSE\_UNSEGMENTED\_PROJECTIONS** sets this value to false, Database Designer proposes only segmented projections.

Privileges

Non-superuser: design creator

Examples

The following example specifies that Database Designer can propose only segmented projections for tables in the design **VMART\_DESIGN** :

```
=> SELECT DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS('VMART_DESIGN', false);
```

See also

[Running Database Designer programmatically](#)

DESIGNER\_SINGLE\_RUN

Evaluates all queries that completed execution within the specified timespan, and returns with a design that is ready for deployment. This design includes projections that are recommended for optimizing the evaluated queries. Unless you redirect output, DESIGNER\_SINGLE\_RUN returns the design to stdout.

**Tip**

Before running DESIGNER\_SINGLE\_RUN, collect statistics on the queried data by calling [ANALYZE\\_STATISTICS](#) and [ANALYZE\\_STATISTICS\\_PARTITION](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_SINGLE_RUN ('interval')
```

**interval**

Specifies an interval of time that precedes the meta-function call. Database Designer evaluates all queries that ran to completion over the specified interval.

Privileges

Superuser or DBUSER

Examples

```

-- SSBM dataset test

-- create ssbm schema
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_schema.sql' > /dev/null 2>&1
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_constraints.sql' > /dev/null 2>&1
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_funcdeps.sql' > /dev/null 2>&1

-- run these queries
\! $TARGET/bin/vsql -f 'sql/SSBM/SSBM_queries.sql' > /dev/null 2>&1
-- Run single API
select designer_single_run('1 minute');

...

## DESIGNER\_WAIT\_FOR\_DESIGN

Waits for completion of operations that are populating and deploying the design. Ctrl+C cancels this operation and returns control to the user.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
DESIGNER_WAIT_FOR_DESIGN ('design-name')
```

Parameters

***design-name***

Name of the running design.

Privileges

Superuser, or DBDUSER with USAGE privilege on the design schema

Examples

The following example requests to wait for the currently running design of VMART\_DESIGN to complete:

```
=> SELECT DESIGNER_WAIT_FOR_DESIGN ('VMART_DESIGN');
```

See also

- [DESIGNER\\_CANCEL\\_POPULATE\\_DESIGN](#)
- [DESIGNER\\_DROP\\_ALL\\_DESIGNS](#)
- [DESIGNER\\_DROP\\_DESIGN](#)

Directed queries functions

The following meta-functions let you batch export query plans as directed queries from one Vertica database, and import those directed queries to another database.

In this section

- [CLEAR\\_DIRECTED\\_QUERY\\_USAGE](#)
- [EXPORT\\_DIRECTED\\_QUERIES](#)
- [IMPORT\\_DIRECTED\\_QUERIES](#)
- [SAVE\\_PLANS](#)

#### CLEAR\_DIRECTED\_QUERY\_USAGE

Resets the counter in the [DIRECTED\\_QUERY\\_STATUS](#) table for a single query or for all queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_DIRECTED_QUERY_USAGE(['query-name'])
```

Arguments

**query-name**

The name of the directed query to reset. If omitted, the function resets counters for all queries.

Privileges

[Superuser](#)

Examples

In the following example, three directed queries have been used:

```
=> SELECT query_name, sum(hits) FROM DIRECTED_QUERY_STATUS GROUP BY 1;
 query_name | sum
-----+-----
findEmployeesCityJobTitle_OPT | 5
save_plans_nolabel_3_3 | 2
save_plans_nolabel_6_3 | 3
(3 rows)
```

After calling the function for one of the queries, its counter is reset to 0:

```
=> SELECT CLEAR_DIRECTED_QUERY_USAGE('findEmployeesCityJobTitle_OPT');
CLEAR_DIRECTED_QUERY_USAGE

Usage cleared.
(1 row)

=> SELECT query_name, sum(hits) FROM DIRECTED_QUERY_STATUS GROUP BY 1;
 query_name | sum
-----+-----
findEmployeesCityJobTitle_OPT | 0
save_plans_nolabel_3_3 | 2
save_plans_nolabel_6_3 | 3
(3 rows)
```

#### EXPORT\_DIRECTED\_QUERIES

Generates SQL for creating directed queries from a set of input queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXPORT_DIRECTED_QUERIES('input-file', '[output-file]')
```

## Arguments

### **input-file**

A SQL file that contains one or more input queries. See [Input Format](#) below for details on format requirements.

### **output-file**

Specifies where to write the generated SQL for creating directed queries. If **output-file** already exists, EXPORT\_DIRECTED\_QUERIES returns with an error. If you supply an empty string, Vertica writes the SQL to standard output. See [Output Format](#) below for details.

## Privileges

### [Superuser](#)

## Input format

The input file that you supply to EXPORT\_DIRECTED\_QUERIES contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- **DirQueryName** provides the directed query's unique identifier, a string that conforms to conventions described in [Identifiers](#).
- **DirQueryComment** specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```
--DirQueryName=query-name
--DirQueryComment='comment'
input-query
```

## Output format

**EXPORT\_DIRECTED\_QUERIES** generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```
/* Query: directed-query-name */
/* Comment: directed-query-comment */
SAVE QUERY input-query;
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'
COMMENT 'directed-query-comment'
OPTVER 'vertica-release-num'
PSDATE 'timestamp'
annotated-query
```

If a given input query omits **DirQueryName** and **DirQueryComment** fields, EXPORT\_DIRECTED\_QUERIES automatically generates the following output:

- **/\* Query: Autaname: *timestamp* . *n* \*/**, where *n* is a zero-based integer index that ensures uniqueness among auto-generated names with the same timestamp.
- **/\* Comment: Optimizer-generated directed query \*/**

## Error handling

If any errors or warnings occur during EXPORT\_DIRECTED\_QUERIES execution, it returns with a message like this one:

```
1 queries successfully exported.
1 warning message was generated.
Queries exported to /home/dbadmin/outputQueries.
See error report, /home/dbadmin/outputQueries.err for details.
```

EXPORT\_DIRECTED\_QUERIES writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

For example:

```

WARNING: Name field not supplied. Using auto-generated name: 'Autaname:2016-04-25 15:03:32.115317.0'
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.job_title FROM
public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
END WARNING
```

## Examples

See [Exporting directed queries](#).

See also

- [Batch query plan export](#)
- [IMPORT\\_DIRECTED\\_QUERIES](#)

## IMPORT\_DIRECTED\_QUERIES

Imports to the database catalog directed queries from a SQL file that was generated by [EXPORT\\_DIRECTED\\_QUERIES](#). If no directed queries are specified, Vertica lists all directed queries in the SQL file.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
IMPORT_DIRECTED_QUERIES('export-file', 'directed-query-name'[...])
```

Arguments

### **export-file**

A SQL file generated by [EXPORT\\_DIRECTED\\_QUERIES](#). When you run this file, Vertica creates the specified directed queries in the current database catalog.

### **directed-query-name**

The name of a directed query that is defined in *export-file*. You can specify multiple comma-delimited directed query names.

If you omit this parameter, Vertica lists the names of all directed queries in *export-file*.

Privileges

[Superuser](#)

Examples

See [Importing directed queries](#).

See also

[Batch query plan export](#)

SAVE\_PLANS

Creates [optimizer-generated](#) directed queries from the most frequently executed queries, up to the maximum specified. You can also limit the scope of SAVE\_PLANS to queries only issued after a specified date.

As SAVE\_PLANS iterates over past queries, it tests them against various restrictions. In general, directed queries support only SELECT statements as input. Within this broad requirement, input queries are subject to other [restrictions](#). After qualifying all candidate input queries, SAVE\_PLANS operates as follows:

1. Calls CREATE DIRECTED QUERY OPTIMIZER on all qualified input queries, which creates a directed query for each unique input query.
2. [Saves metadata](#) on the new set of directed queries to the system table [DIRECTED\\_QUERIES](#), where all directed queries of that set share the same integer identifier.

All directed queries created by SAVE\_PLANS are initially inactive. You can activate them individually; you can also use [SAVE\\_PLANS\\_VERSION](#) identifiers to [activate](#), [deactivate](#), and [drop](#) one or more sets of directed queries.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SAVE_PLANS(query-budget [, since-date] [, drop-old-plans[, 'comment']])
```

Arguments

### **query-budget**

Maximum number of input queries to save as directed queries, an integer between 1 and 100, inclusive.

### **since-date**

The earliest timestamp of input queries to save as directed queries.

### **drop-old-plans**

Boolean, specifies whether to drop all directed queries generated by earlier SAVE\_PLANS invocations. Only directed queries that were generated by the current Vertica version are dropped; directed queries generated by earlier Vertica versions are untouched. To drop older

directed queries, use [DROP DIRECTED QUERY](#).

### comment

String comment that is attached to all plans saved with this function call.

### Privileges

[Superuser](#)

### Generated metadata

For each set of directed queries that SAVE\_PLANS creates, Vertica updates the system table [DIRECTED\\_QUERIES](#) with metadata on each directed query in the set:

Column name	SAVE_PLANS-generated data
QUERY_NAME	Concatenated from the following strings: <div style="border: 1px solid black; padding: 2px; margin: 5px 0;"><code>save_plans_query-label_query-number_save-plans-version</code></div> where: <ul style="list-style-type: none"><li><code>query-label</code> is a <a href="#">LABEL</a> hint embedded in the input query associated with this directed query. If the input query contains no label, then this string is set to <code>nolabel</code>.</li><li><code>query-number</code> is an integer in a continuous sequence between 0 and <code>budget-query</code>, which uniquely identifies this directed query from others in the same SAVE_PLANS-generated set.</li><li><code>[save-plans-version]/(sql-reference/system-tables/v-catalog-schema/directed-queries.html#SAVE_PLANS_VERSION)</code> identifies the set of directed queries to which this directed query belongs.</li></ul>
SAVE_PLANS_VERSION	Identifies a set of directed queries that were generated by the same call to SAVE_PLANS. All directed queries of the set share the same <code>SAVE_PLANS_VERSION</code> integer, which increments by 1 the previous highest <code>SAVE_PLANS_VERSION</code> setting. Use this identifier to <a href="#">activate</a> , <a href="#">deactivate</a> , and <a href="#">drop</a> a set of directed queries.
USERNAME	User who invoked SAVE_PLANS to create this set of directed queries.
SINCE_DATE	The <code>since-date</code> timestamp supplied to SAVE_PLANS, which specified the earliest timestamp of input queries to evaluate as directed query candidates.
DIGEST	Hash of saved query plan data, used by the optimizer to map identical input queries to the same active directed query.

### Examples

See [Bulk-Creation of Directed Queries](#).

### Error-handling functions

Error-handling functions take a string and return the string when the query is executed.

In this section

- [THROW\\_ERROR](#)

#### THROW\_ERROR

Returns a user-defined error message.

In a multi-node cluster, race conditions might cause the order of error messages to differ.

#### Behavior type

[Immutable](#)

#### Syntax

```
THROW_ERROR (message)
```

#### Parameters

##### **message**

The VARCHAR string to return.

## Examples

Return an error message when a CASE statement is met:

```
=> CREATE TABLE pitcher_err (some_text varchar);
CREATE TABLE
=> COPY pitcher_err FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> big foo value
>> bigger foo other value
>> bar another foo value
>> \.
=> SELECT (CASE WHEN true THEN THROW_ERROR('Failure!!!') ELSE some_text END) FROM pitcher_err;
ERROR 7137: USER GENERATED ERROR: Failure!!!
```

Return an error message when a CASE statement using [REGEXP\\_LIKE](#) is met:

```
=> SELECT (CASE WHEN REGEXP_LIKE(some_text, 'other') THEN THROW_ERROR("Failure at " || some_text || ")") END) FROM pitcher_err;
ERROR 4566: USER GENERATED ERROR: Failure at "bar another foo value"
```

## Flex functions

This section contains helper functions for use in working with flex tables and flexible columns for complex types. You can use these functions with flex tables, their associated [flex\\_table\\_keys](#) tables and [flex\\_table\\_view](#) views, and flexible columns in external tables. These functions do not apply to other tables.

For more information about flex tables, see [Flex tables](#). For more information about flexible columns for complex types, see [Flexible complex types](#).

Flex functions allow you to manage and query flex tables. You can also use the map functions to query flexible complex-type columns in non-flex tables.

In this section

- [Flex data functions](#)
- [Flex extractor functions](#)
- [Flex map functions](#)

## Flex data functions

The flex table data helper functions supply information you need to directly query data in flex tables. After you compute keys and create views from the raw data, you can use field names directly in queries instead of using map functions to extract data. The data functions are:

- [COMPUTE\\_FLEXTABLE\\_KEYS](#): Computes map keys from the map data in a flex table and populates a keys table with the results. Use this function before building a view.
- [BUILD\\_FLEXTABLE\\_VIEW](#): Uses the keys in a table to create a view definition for the source table. Use this function after computing flex table keys.
- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#): Performs both of the preceding functions in one call.
- [MATERIALIZATE\\_FLEXTABLE\\_COLUMNS](#): Materializes a specified number of columns.
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#): Replaces the [flextable\\_data\\_keys](#) table and the [flextable\\_data\\_view](#) view, linking both the keys table and the view to the parent flex table.

## Flex table dependencies

Each flex table has two dependent objects, a keys table and a view. While both objects are dependent on their parent table, you can drop either object independently. Dropping the parent table removes both dependents, without a CASCADE option.

## Associating flex tables and views

The helper functions automatically use the dependent table and view if they are internally linked with the parent table. You create both when you create the flex table. You can drop either the keys table or the view and re-create objects of the same name. However, if you do so, the new objects are not internally linked with the parent flex table.

In this case, you can restore the internal links of these objects to the parent table. To do so, drop the keys table and the view before calling the [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#) function. Calling this function re-creates the keys table and view.

The remaining helper functions perform the tasks described in this section.

In this section

- [BUILD\\_FLEXTABLE\\_VIEW](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [MATERIALIZATE\\_FLEXTABLE\\_COLUMNS](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

## BUILD\_FLEXTABLE\_VIEW

Creates, or re-creates, a view for a default or user-defined keys table, ignoring any empty keys.

### Note

If the length of a key exceeds 65,000, Vertica truncates the key.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
BUILD_FLEXTABLE_VIEW ('[[database.]schema.]flex-table'
 [,['view-name'] [,'user-keys-table']])
```

Arguments

[ **database** .] **schema**

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

**flex-table**

The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated [flex\\_table\\_keys](#) table.

**view-name**

A custom view name. Use this option to build a new view for [flex-table](#) with the name you specify.

**user-keys-table**

Name of a keys table from which to create the view. Use this option if you created a custom keys table from the flex table map data, rather than from the default [flex\\_table\\_keys](#) table. The function builds a view from the keys in [user\\_keys](#), rather than from [flex\\_table\\_keys](#).

Examples

The following examples show how to call BUILD\_FLEXTABLE\_VIEW with 1, 2, or 3 arguments.

To create, or re-create, a default view:

1. Call the function with an input flex table:

```
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata');
 build_flextable_view

The view public.darkdata_view is ready for querying
(1 row)
```

The function creates a view with the default name ( [darkdata\\_view](#) ) from the [darkdata](#) \_keys table.

2. Query a key name from the new or updated view:

```

=> SELECT "user.id" FROM darkdata_view;
user.id

340857907
727774963
390498773
288187825
164464905
125434448
601328899
352494946
(12 rows)

```

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, `darkdata`, and the name of the view to create, `dd_view` :

```

=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view');
 build_flextable_view

The view public.dd_view is ready for querying
(1 row)

```

2. Query a key name ( `user.lang` ) from the new or updated view ( `dd_view` ):

```

=> SELECT "user.lang" FROM dd_view;
user.lang

tr
en
es
en
en
it
es
en
(12 rows)

```

To create a view from a custom keys table with `BUILD_FLEXTABLE_VIEW`, the custom table must have the same schema and table definition as the default table ( `darkdata_keys` ). Create a custom keys table, using any of these three approaches:

- Create a columnar table with all keys from the default keys table for a flex table ( `darkdata_keys` ):

```

=> CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys;
CREATE TABLE

```

- Create a columnar table without content ( `LIMIT 0` ) from the default keys table for a flex table ( `darkdata_keys` ):

```

=> CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys LIMIT 0;
CREATE TABLE
kdb=> SELECT * FROM new_darkdata_keys;
key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)

```

- Create a columnar table without content ( `LIMIT 0` ) from the default keys table, and insert two values ( ' `user.lang` ', ' `user.name` ' ) into the `key_name` column:

```

=> CREATE TABLE dd_keys AS SELECT * FROM darkdata_keys limit 0;
CREATE TABLE
=> INSERT INTO dd_keys (key_name) values ('user.lang');
OUTPUT

 1
(1 row)
=> INSERT INTO dd_keys (key_name) values ('user.name');
OUTPUT

 1
(1 row)
=> SELECT * FROM dd_keys;
key_name | frequency | data_type_guess
-----+-----+-----
user.lang | |
user.name | |
(2 rows)

```

After creating a custom keys table, call BUILD\_FLEXTABLE\_VIEW with all arguments (an input flex table, the new view name, the custom keys table):

```

=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');
 build_flextable_view

The view public.dd_view is ready for querying
(1 row)

```

Query the new view:

```

=> SELECT * FROM dd_view;

```

See also

- [COMPUTE\\_FLEXTABLE\\_KEYS](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [MATERIALIZE\\_FLEXTABLE\\_COLUMNS](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

## COMPUTE\_FLEXTABLE\_KEYS

Computes the virtual columns (keys and values) from flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

COMPUTE_FLEXTABLE_KEYS ('[[database.]schema.]flex-table')

```

Arguments

[ **database** .] **schema**

Database and [schema](#). The default schema is [public](#). If you specify a database, it must be the current database.

**flex-table**

Name of the flex table.

Output

The function stores its results in a table named [flex-table\\_keys](#). The table has the following columns:

Column	Description
KEY_NAME	The name of the virtual column (key). Keys larger than 65,000 bytes are truncated.

FREQUENCY	The number of times the key occurs in the VMap.
DATA_TYPE_GUESS	Estimate of the data type for the key based on the non-null values found in the VMap. The function determines the type of each non-string value, depending on the length of the key, and whether the key includes nested maps. If the <a href="#">EnableBetterFlexTypeGuessing</a> configuration parameter is 0 (OFF), this function instead treats all flex table keys as string types ([LONG] VARCHAR or [LONG] VARBINARY).

COMPUTE\_FLEXTABLE\_KEYS sets the column width for keys to the length of the largest value for each key multiplied by the [FlexTableDataTypeGuessMultiplier](#) factor.

#### Examples

In the following example, JSON data with consistent fields has been loaded into a flex table. Had the data been more varied, you would see different numbers of occurrences in the keys table:

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('reviews_flex');
 COMPUTE_FLEXTABLE_KEYS
```

Please see public.reviews\_flex\_keys for updated keys

(1 row)

```
SELECT * FROM reviews_flex_keys;
```

```
key_name | frequency | data_type_guess
```

```
-----+-----
user_id | 1000 | Varchar(44)
useful | 1000 | Integer
text | 1000 | Varchar(9878)
stars | 1000 | Numeric(5,2)
review_id | 1000 | Varchar(44)
funny | 1000 | Integer
date | 1000 | Timestamp
cool | 1000 | Integer
business_id | 1000 | Varchar(44)
```

(9 rows)

- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [MATERIALIZATE\\_FLEXTABLE\\_COLUMNS](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

#### COMPUTE\_FLEXTABLE\_KEYS\_AND\_BUILD\_VIEW

Combines the functionality of [BUILD\\_FLEXTABLE\\_VIEW](#) and [COMPUTE\\_FLEXTABLE\\_KEYS](#) to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

#### Note

If the length of a key exceeds 65,000, Vertica truncates the key.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW ('flex-table')
```

Arguments

**flex-table**

Name of a flex table

## Examples

This example shows how to call the function for the darkdata flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('darkdata');
 compute_flextable_keys_and_build_view
```

Please see `public.darkdata_keys` for updated keys

The view `public.darkdata_view` is ready for querying

(1 row)

See also

- [BUILD\\_FLEXTABLE\\_VIEW](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS](#)
- [MATERIALIZED\\_FLEXTABLE\\_COLUMNS](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

## MATERIALIZED\_FLEXTABLE\_COLUMNS

Materializes virtual columns listed as *key\_names* in the *flextable\_keys* table you compute using either [COMPUTE\\_FLEXTABLE\\_KEYS](#) or [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#).

### Note

Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the `AUDIT()` or `AUDIT_FLEX()` functions.

This is a meta-function. You must call meta-functions in a top-level `SELECT` statement.

Behavior type

[Volatile](#)

Syntax

```
MATERIALIZED_FLEXTABLE_COLUMNS ('[[database.]schema.]flex-table' [, n-columns [, keys-table-name]])
```

Arguments

[ *database* .] *schema*

Database and [schema](#). The default schema is `public`. If you specify a database, it must be the current database.

### *flex-table*

The name of the flex table with columns to materialize. The function:

- Skips any columns already materialized
- Ignores any empty keys

### *n-columns*

The number of columns to materialize, up to 9800. The function attempts to materialize the number of columns from the keys table, skipping any columns already materialized. It orders the materialized results by frequency, descending. If not specified, the default is a maximum of 50 columns.

### *keys-table-name*

The name of a keys from which to materialize columns. The function:

- Materializes *n-columns* columns from the keys table
- Skips any columns already materialized
- Orders the materialized results by frequency, descending

Examples

The following example shows how to call `MATERIALIZED_FLEXTABLE_COLUMNS` to materialize columns. First, load a sample file of tweets (`tweets_10000.json`) into the flex table `twitter_r`. After loading data and computing keys for the sample flex table, call `MATERIALIZED_FLEXTABLE_COLUMNS` to materialize the first four columns:

```
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
```

Rows Loaded

```

 10000
(1 row)
```

```
=> SELECT compute_flexable_keys ('twitter_r');
 compute_flexable_keys
```

```

Please see public.twitter_r_keys for updated keys
(1 row)
```

```
=> SELECT MATERIALIZE_FLEXTABLE_COLUMNS('twitter_r', 4);
 MATERIALIZE_FLEXTABLE_COLUMNS
```

```

The following columns were added to the table public.twitter_r:
```

```
 contributors
 entities.hashtags
 entities.urls
```

For more details, run the following query:

```
SELECT * FROM v_catalog.materialize_flexable_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';
```

```
(1 row)
```

The last message in the example recommends querying the [MATERIALIZE\\_FLEXTABLE\\_COLUMNS\\_RESULTS](#) system table for the results of materializing the columns, as shown:

```
=> SELECT * FROM v_catalog.materialize_flexable_columns_results WHERE table_schema = 'public' and table_name = 'twitter_r';
```

table_id	table_schema	table_name	creation_time	key_name	status	message
45035996273733172	public	twitter_r	2013-11-20 17:00:27.945484-05	contributors	ADDED	Added successfully
45035996273733172	public	twitter_r	2013-11-20 17:00:27.94551-05	entities.hashtags	ADDED	Added successfully
45035996273733172	public	twitter_r	2013-11-20 17:00:27.945519-05	entities.urls	ADDED	Added successfully
45035996273733172	public	twitter_r	2013-11-20 17:00:27.945532-05	created_at	EXISTS	Column of same name already

(4 rows)

See also

- [BUILD\\_FLEXTABLE\\_VIEW](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

### RESTORE\_FLEXTABLE\_DEFAULT\_KEYS\_TABLE\_AND\_VIEW

Restores the keys table and the view. The function also links the keys table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW ('flex-table')
```

Arguments

**flex-table**

Name of a flex table

Examples

This example shows how to invoke this function with an existing flex table, restoring both the keys table and view:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
 RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
```

-----

The keys table public.darkdata\_keys was restored successfully.

The view public.darkdata\_view was restored successfully.

(1 row)

This example illustrates that the function restored `darkdata_view`, but that `darkdata_keys` did not need restoring:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
 RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
```

-----

The keys table public.darkdata\_keys already exists and is linked to darkdata.

The view public.darkdata\_view was restored successfully.

(1 row)

After restoring the keys table, there is no content. To populate the flex keys, call the [COMPUTE\\_FLEXTABLE\\_KEYS](#) function.

```
=> SELECT * FROM darkdata_keys;
key_name | frequency | data_type_guess
```

-----

(0 rows)

See also

- [BUILD\\_FLEXTABLE\\_VIEW](#)

- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [MATERIALIZATE\\_FLEXTABLE\\_COLUMNS](#)

Flex extractor functions

The flex extractor scalar functions process polystructured data. Each function accepts input data that is any of:

- Existing database content
- A table
- Returned from an expression
- Entered directly

These functions do not parse data from an external file source. All functions return a single VMap value. The extractor functions can return data with NULL-specified columns.

In this section

- [MAPDELIMITEXTRACTOR](#)
- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

MAPDELIMITEXTRACTOR

Extracts data with a delimiter character and other optional arguments, returning a single VMap value.

Syntax

```
MAPDELIMITEXTRACTOR (record-value [USING PARAMETERS param=value[,...]])
```

Arguments

***record-value***

String containing a JSON or delimited format record on which to apply the expression.

Parameters

**delimiter**

Single delimiter character.

**Default:** |

**header\_names**

Delimiter-separated list of column header names.

**Default:** `ucol n`, where `n` is the column offset number, starting with `0` for the first column.

### trim

Boolean, trim white space from header names and field values.

**Default:** `true`

### treat\_empty\_val\_as\_null

Boolean, set empty fields to `NULL` rather than an empty string ( `"` ).

**Default:** `true`

### Examples

These examples use a short set of delimited data:

```
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|01
Eric|Burlington|BURLINGTON|MA|02
Jamie|cambridge|CAMBRIDGE|MA|08
```

To begin, save this data as `delim.dat`.

1. Create a flex table, `dflex` :

```
=> CREATE FLEX TABLE dflex();
CREATE TABLE
```

2. Use [COPY](#) to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the `header='false'` option:

```
=> COPY dflex FROM '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser(header='false');
```

Rows Loaded

```

 4
(1 row)
```

3. Create a columnar table, `dtab`, with an identity `id` column, a `delim` column, and a `vmap` column to hold a VMap:

```
=> CREATE TABLE dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));
CREATE TABLE
```

4. Use `COPY` to load the `delim.dat` file into the `dtab` table. `MAPDELIMITEDEXTRACTOR` uses the `header_names` parameter to specify a header row for the sample data, along with `delimiter '!' :`

```
=> COPY dtab(delim, vmap AS MAPDELIMITEDEXTRACTOR (delim
 USING PARAMETERS header_names='Name|CITY|New City|State|Zip')) FROM '/home/dbadmin/data/delim.dat'
DELIMITER '!';
```

Rows Loaded

```

 4
(1 row)
```

5. Use [MAPTOSTRING](#) for the flex table `dflex` to view the `__raw__` column contents. Notice the default header names in use ( `ucol0` – `ucol4` ), since you specified `header='false'` when you loaded the flex table:

```
=> SELECT MAPTOSTRING(__raw__) FROM dflex limit 10;
```

```
maptostring
```

```

{
 "ucol0" : "Jamie",
 "ucol1" : "cambridge",
 "ucol2" : "CAMBRIDGE",
 "ucol3" : "MA",
 "ucol4" : "08"
}
```

```
{
 "ucol0" : "Name",
 "ucol1" : "CITY",
 "ucol2" : "New city",
 "ucol3" : "State",
 "ucol4" : "zip"
}
```

```
{
 "ucol0" : "Tom",
 "ucol1" : "BOSTON",
 "ucol2" : "boston",
 "ucol3" : "MA",
 "ucol4" : "01"
}
```

```
{
 "ucol0" : "Eric",
 "ucol1" : "Burlington",
 "ucol2" : "BURLINGTON",
 "ucol3" : "MA",
 "ucol4" : "02"
}
```

```
(4 rows)
```

6. Use MAPTOSTRING again, this time with the `dtab` table's `vmap` column. Compare the results of this output to those for the flex table. Note that MAPTOSTRING returns the `header_name` parameter values you specified when you loaded the data:

```
=> SELECT MAPTOSTRING(vmap) FROM dtab;
 maptostring
```

```

{
 "CITY" : "CITY",
 "Name" : "Name",
 "New City" : "New city",
 "State" : "State",
 "Zip" : "zip"
}

{
 "CITY" : "BOSTON",
 "Name" : "Tom",
 "New City" : "boston",
 "State" : "MA",
 "Zip" : "02121"
}

{
 "CITY" : "Burlington",
 "Name" : "Eric",
 "New City" : "BURLINGTON",
 "State" : "MA",
 "Zip" : "02482"
}

{
 "CITY" : "cambridge",
 "Name" : "Jamie",
 "New City" : "CAMBRIDGE",
 "State" : "MA",
 "Zip" : "02811"
}
```

(4 rows)

7. Query the `delim` column to view the contents differently:

```
=> SELECT delim FROM dtab;
 delim
```

```

Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|02121
Eric|Burlington|BURLINGTON|MA|02482
Jamie|cambridge|CAMBRIDGE|MA|02811
```

(4 rows)

- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

## MAPJSONEXTRACTOR

Produces a VMap of key/value pairs from an input JSON string. You typically use this function with COPY to populate a VMap column from another string column containing the JSON.

Empty input does not generate warnings or errors.

### Syntax

```
MAPJSONEXTRACTOR (record-value [USING PARAMETERS param=value[,...]])
```

### Arguments

### **record-value**

String containing a JSON or delimited format record on which to apply the expression.

#### Parameters

#### **flatten\_maps (Boolean)**

If true, flatten sub-maps within the JSON data, separating map levels with periods ( . ).

**Default:** true

#### **flatten\_arrays (Boolean)**

If true, convert lists to sub-maps with integer keys. Lists are not flattened by default.

**Default value:** false

#### **reject\_on\_duplicate (Boolean)**

If true, reject duplicates. If false, ignore duplicate records. In either case, loading is unaffected.

**Default:** false

#### **reject\_on\_empty\_key (Boolean)**

If true, reject any row that contains a key without a value.

**Default:** false

#### **omit\_empty\_keys (Boolean)**

If true, omit any key from the data without a value.

**Default:** false

#### **start\_point (String)**

Name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the **start\_point** value. The parser processes data after the first instance, and up to the second, ignoring any remaining data.

**Default:** none

#### Examples

This example uses the following sample JSON data in a file named **bakery.json** :

```
{ "id": "5001", "type": "None" }
{ "id": "5002", "type": "Glazed" }
{ "id": "5005", "type": "Sugar" }
{ "id": "5007", "type": "Powdered Sugar" }
{ "id": "5004", "type": "Maple" }
```

In addition to loading this data as a string, you can load it as a VMap using this function:

```
=> CREATE TABLE bakery(id IDENTITY(1,1), json VARCHAR(128), vmap LONG VARBINARY(10000));
CREATE TABLE
=> COPY bakery (json, vmap AS MapJSONExtractor(json))
 FROM 'home/dbadmin/data/bakery.json';
Rows Loaded

 5
(1 row)
```

You can now use [MAPTOSTRING](#) to show the values from the VMap:

```

=> SELECT MAPTOSTRING(vmap) FROM bakery limit 5;
 maptostring

{"id": "5001",
 "type": "None"}

{"id": "5002",
 "type": "Glazed"}

{"id": "5004",
 "type": "Maple"}

{"id": "5005",
 "type": "Sugar"}

{"id": "5007",
 "type": "Powdered Sugar"}

(5 rows)

```

If you load the data into a flex table, you must qualify the filler column to disambiguate it from possible fields in the VMap. Use the following syntax to refer to a filler column when loading into a flex table:

```

=> CREATE FLEX TABLE bakery2(id IDENTITY(1,1), vmap LONG VARBINARY(10000));
CREATE TABLE

=> COPY bakery2 (json FILLER VARCHAR(128),
 vmap AS MapJSONExtractor("**FILLER**".json))
 FROM '/home/dbadmin/data/bakery.json';
Rows Loaded

 5
(1 row)

```

If you call MAPTOSTRING on the `__raw__` column in this flex table, the order of elements might be different from the previous example, but the output is otherwise the same.

- [MAPDELIMITEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

## MAPREGEXEXTRACTOR

Extracts data with a regular expression and returns results as a VMap.

Syntax

```
MAPREGEXEXTRACTOR (record-value [USING PARAMETERS param=value[,...]])
```

Arguments

### **record-value**

String containing a JSON or delimited format record on which to apply the regular expression.

Parameters

## pattern

Regular expression used to extract the desired data.

**Default:** Empty string ( " )

## use\_jit

Boolean, use just-in-time compiling when parsing the regular expression.

**Default:** false

## record\_terminator

Character used to separate input records.

**Default:** \n

## logline\_column

Destination column containing the full string that the regular expression matched.

**Default:** Empty string ( " )

## Examples

These examples use the following regular expression, which searches for information that includes the **timestamp** , **date** , **thread\_name** , and **thread\_id** strings.

### Caution

For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any **thread\_id** hex value, regardless of whether it has a **0x** prefix, (`<thread_id>(?:0x)?[0-9a-f]+`) .

```
^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+)
(?<thread_name>[A-Za-z]+):(?<thread_id>(?:0x)?[0-9a-f]+)
(?<transaction_id>[0-9a-f])?(?:[?<component>\w+])
<(?<level>\w+)\>)?(?:<(?<elevel>\w+)\> @[?<enode>\w+]]? :)?(?<text>.*)'
```

The following examples may include newline characters for display purposes.

1. Create a flex table, **flogs** :

```
=> CREATE FLEX TABLE flogs();
CREATE TABLE
```

2. Use [COPY](#) to load a sample log file ( **vertica.log** ), using the flex table **fregexparser** . Note that this example includes added line characters for displaying long text lines.

```
=> COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='
^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+)
(?<thread_name>[A-Za-z]+):
(?<thread_id>(?:0x)?[0-9a-f])-(?<transaction_id>[0-9a-f])?(?:[?<component>\w+])
\<(?<level>\w+)\>)?(?:<(?<elevel>\w+)\> @[?<enode>\w+]]? :)?(?<text>.*)';
Rows Loaded

81399
(1 row)
```

3. Use to return the results from calling MAPREGEXEXTRACTOR with a regular expression. The output returns the results of the function in string format.

```
=> SELECT MAPTOSTRING(MapregexExtractor(E'2014-04-02 04:02:51.011
TM Moveout:0x2aab9000f860-a000000002067 [Txn] <INFO>
Begin Txn: a000000002067 \Moveout: Tuple Mover\" using PARAMETERS
pattern=
```

```
{(?<time>[0-9]{4}-[0-9]{2}-[0-9]{2} [0-9]{2}:[0-9]{2}:[0-9]{3})
(?<thread_name>[A-Za-z]+).(?(thread_id)(?0x)?[0-9a-f]{+})
.(?(transaction_id)[0-9a-f]{+})(?(component)[w+])
.(?(level)[w+])?(?(?<level>[w+])> @[(?(?<enode>[w+])]?):
?(?<text>.*)
```

```
) FROM flogs where __identity__=13;
maptostring
```

```

{
"component" : "Txn",
"level" : "INFO",
"text" : "Begin Txn: a000000002067 'Moveout: Tuple Mover'",
"thread_id" : "0x2aab9000f860",
"thread_name" : "TM Moveout",
"time" : "2014-04-02 04:02:51.011",
"transaction_id" : "a000000002067"
}
(1 row)
```

Flex map functions

The flex map functions let you extract and manipulate nested map data.

The first argument of all flex map functions (except EMPTYMAP and MAPAGGREGATE ) takes a VMap. The VMap can originate from the `__raw__` column in a flex table or be returned from a map or extraction function.

All map functions (except EMPTYMAP and MAPAGGREGATE ) accept either a LONG VARBINARY or a LONG VARCHAR map argument.

In the following example, the outer MAPLOOKUP function operates on the VMap data returned from the inner MAPLOOKUP function:

```
=> MAPLOOKUP(MAPLOOKUP(ret_map, 'batch'), 'scripts')
```

You can use flex map functions exclusively with:

- Flex tables
- Their associated `_keys` tables and `_view` views
- Flexible complex-type columns

In this section

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPPUT](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## EMPTYMAP

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

### Syntax

```
EMPTYMAP()
```

### Examples

#### Create an Empty Map

```
=> SELECT EMPTYMAP();
 emptymap

\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
(1 row)
```

#### Create an Empty Map from an Existing Flex Table

If you create an empty map from an existing flex table, the new map has the same number of rows as the table from which it was created.

This example shows the result if you create an empty map from the [darkdata](#) table, which has 12 rows of JSON data:

```
=> SELECT EMPTYMAP() FROM darkdata;
 emptymap

\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000
(12 rows)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPAGGREGATE

Returns a LONG VARBINARY VMap with key and value pairs supplied from two VARCHAR input columns. This function requires an OVER clause.

### Syntax

```
MAPAGGREGATE (keys-column1, values-column2 [USING PARAMETERS param=value[...]])
```

### Arguments

**keys-column**

Table column with the keys for the key/value pairs of the returned **VMap** data. Keys with a NULL value are excluded. If there are duplicate keys, the duplicate key and value that appear first in the query result are used, while the other duplicates are omitted.

### values-column

Table column with the values for the key/value pairs of the returned **VMap** data.

### Parameters

#### max\_vmap\_length

Maximum length in bytes for the VMap result, an integer between 1-32000000 inclusive.

**Default:** 130000

#### on\_overflow

Overflow behavior for cases when the VMap result is larger than the **max\_vmap\_length** . The value must be one of the following strings:

- 'ERROR': Returns an error when overflow occurs.
- 'TRUNCATE': Stops aggregating key/value pairs if the result exceeds **max\_vmap\_length** . The query executes, but the resulting VMap does not have all key/value pairs. When the provided **max\_vmap\_length** is not large enough to store an empty VMap, the result returned is NULL.

Note that you need to specify order criteria in the OVER clause to get consistent results.

- 'RETURN\_NULL': Return NULL if overflow occurs.

**Default:** 'ERROR'

### Examples

The following examples use this input table:

```
=> SELECT * FROM inventory;
product | stock
-----+-----
Planes | 100
Trains | 50
Automobiles | 200
(3 rows)
```

Call MAPAGGREGATE as follows to return the **raw\_map** data of the resulting VMap:

```
=> SELECT raw_map FROM (SELECT MAPAGGREGATE(product, stock) OVER(ORDER BY product) FROM inventory) inventory;
raw_map

\001\000\000\000\030\000\000\000\003\000\000\000\020\000\000\000\023\000\000\000\026\000\000\000\00200\0050\003
\000\000\000\020\000\000\000\033\000\000\000\!000\000\000AutomobilesPlanesTrains
(1 row)
```

To transform the returned **raw\_map** data into string representation, use MAPAGGREGATE with **MAPTOSTRING**:

```
=> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(product, stock) OVER(ORDER BY product) FROM
inventory) inventory;
MAPTOSTRING

{
 "Automobiles": "200",
 "Planes": "100",
 "Trains": "50"
}
(1 row)
```

If you run the above query with **on\_overflow** left as default and a **max\_vmap\_length** less than the returned VMap size, the function returns with an error message indicating the need to increase VMap length:

```
=> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60)
OVER(ORDER BY product) FROM inventory) inventory;
```

```

ERROR 5861: Error calling processPartition() in User Function MapAggregate at [/data/jenkins/workspace
/RE-PrimaryBuilds/RE-Build-Master_2/server/udx/supported/flextable/Dict.cpp:1324], error code: 0, message:
Exception while finalizing map aggregation: Output VMap length is too small [60]. HINT: Set the parameter
max_vmap_length=71 and retry your query
```

Switching the value of `on_overflow` allows you to alter how MAPAGGREGATE behaves in the case of overflow. For example, changing `on_overflow` to 'RETURN\_NULL' causes the above query to execute and return NULL:

```
SELECT raw_map IS NULL FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60,
on_overflow='RETURN_NULL') OVER(ORDER BY product) FROM inventory) inventory;
?column?

t
(1 row)
```

If `on_overflow` is set to 'TRUNCATE', the resulting VMap has enough space for two of the key/value pairs, but must cut the third:

```
SELECT raw_map IS NULL FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60,
on_overflow='TRUNCATE') OVER(ORDER BY product) FROM inventory) inventory;
MAPTOSTRING

{
 "Automobiles": "200",
 "Planes": "100"
}
(1 row)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key). This scalar function returns true ( `t` ), if the virtual column exists, or false ( `f` ) if it does not. Determining that a key exists before calling `maplookup()` lets you distinguish between NULL returns. The `maplookup()` function uses for both a non-existent key and an existing key with a NULL value.

Syntax

```
MAPCONTAINSKEY (VMap-data, 'virtual-column-name')
```

Arguments

### **VMap-data**

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

### *virtual-column-name*

Name of the key to check.

### Examples

This example shows how to use the `mapcontainskey()` functions with `maplookup()`. View the results returned from both functions. Check whether the empty fields that `maplookup()` returns indicate a `NULL` value for the row (`t`) or no value (`f`):

You can use `mapcontainskey()` to determine that a key exists before calling `maplookup()`. The `maplookup()` function uses both `NULL` returns and existing keys with `NULL` values to indicate a non-existent key.

```
=> SELECT MAPLOOKUP(__row__, 'user.location'), MAPCONTAINSKEY(__row__, 'user.location')
```

```
FROM darkdata ORDER BY 1;
```

```
maplookup | mapcontainskey
```

```
-----+-----
```

```
 | t
 | t
 | t
 | t
Chile | t
Narnia | t
Uptown.. | t
chicago | t
 | f
 | f
 | f
 | f
```

```
(12 rows)
```

### See also

- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

### MAPCONTAINSVALUE

Determines whether a VMap contains a specific value. Use this scalar function to return true (`t`) if the value exists, or false (`f`) if it does not.

### Syntax

```
MAPCONTAINSVALUE (VMap-data, 'virtual-column-value'
```

### Arguments

#### ***VMap-data***

Any VMap data. The VMap can exist as:

- The `__row__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

#### ***virtual-column-value***

Value to confirm.

### Examples

This example shows how to use `mapcontainsvalue()` to determine whether or not a virtual column contains a particular value. Create a flex table ( `ftest` ), and populate it with some virtual columns and values. Name both virtual columns `one` :

```
=> CREATE FLEX TABLE ftest();
CREATE TABLE
=> copy ftest from stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one":1, "two":2}
>> {"one":"one", "2":"2"}
>> \.
```

Call `mapcontainsvalue()` on the `ftest` map data. The query returns false ( `f` ) for the first virtual column, and true ( `t` ) for the second , which contains the value `one` :

```
=> SELECT MAPCONTAINSVALUE(__row__, 'one') FROM ftest;
mapcontainsvalue

f
t
(2 rows)
```

- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPITEMS

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystructured values within the VMap data. This function requires an `over()` clause.

Syntax

```
MAPITEMS (VMap-data [, passthrough-arg[,...]])
```

Arguments

### **VMap-data**

Any VMap data. The VMap can exist as:

- The `__row__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

### **max\_key\_length**

In a `__row__` column, determines the maximum length of keys that the function can return. Keys that are longer than `max_key_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

### **max\_value\_length**

In a `__row__` column, determines the maximum length of values the function can return. Values that are larger than `max_value_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

### **passthrough-arg**

One or more arguments indicating keys within the map data in `VMap-data` .

Examples

The following examples illustrate using `MAPITEMS()` with the `over(PARTITION BEST)` clause.

This example determines the number of virtual columns in the map data using a flex table, labeled `darkmountain` . Query using the `count()` function to return the number of virtual columns in the map data:

```
=> SELECT COUNT(keys) FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM
darkmountain) AS a;
count

 19
(1 row)
```

The next example determines what items exist in the map data:

```
=> SELECT * FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
 keys | values
-----+-----
hike_safety | 50.6
name | Mt Washington
type | mountain
height | 17000
hike_safety | 12.2
name | Denali
type | mountain
height | 29029
hike_safety | 34.1
name | Everest
type | mountain
height | 14000
hike_safety | 22.8
name | Kilimanjaro
type | mountain
height | 29029
hike_safety | 15.4
name | Mt St Helens
type | volcano
(19 rows)
```

The following example shows how to restrict the length of returned values to 100000:

```
=> SELECT LENGTH(keys), LENGTH(values) FROM (SELECT MAPITEMS(__raw__ USING PARAMETERS max_value_length=100000) OVER() FROM t1)
x;
LENGTH | LENGTH
-----+-----
 9 | 98899
(1 row)
```

### Directly Query a Key Value in a VMap

Review the following JSON input file, `simple.json` . In particular, notice the array called `three_Array` , and its four values:

```
{
 "one": "one",
 "two": 2,
 "three_Array":
 [
 "three_One",
 "three_Two",
 3,
 "three_Four"
],
 "four": 4,
 "five_Map":
 {
 "five_One": 51,
 "five_Two": "Fifty-two",
 "five_Three": "fifty three",
 "five_Four": 54,
 "five_Five": "5 x 5"
 },
 "six": 6
}
```

1. Create a flex table, mapper:

```
=> CREATE FLEX TABLE mapper();
CREATE TABLE
```

Load [simple.json](#) into the flex table mapper:

```
=> COPY mapper FROM '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false,
flatten_maps=false);
Rows Loaded

 1
(1 row)
```

Call MAPKEYS on the flex table's `__raw__` column to see the flex table's keys, but not the key submaps. The return values indicate [three\\_Array](#) as one of the virtual columns:

```
=> SELECT MAPKEYS(__raw__) OVER() FROM mapper;
keys

five_Map
four
one
six
three_Array
two
(6 rows)
```

Call `mapitems` on flex table `mapper` with `three_Array` as a pass-through argument to the function. The call returns these array values:

```
=> SELECT __identity__, MAPITEMS(three_Array) OVER(PARTITION BY __identity__) FROM mapper;
__identity__ | keys | values
-----+-----+-----
 1 | 0 | three_One
 1 | 1 | three_Two
 1 | 2 | 3
 1 | 3 | three_Four
(4 rows)
```

- [MAPVERSION](#)

## MAPKEYS

Returns the virtual columns (and values) present in any VMap data. This transform function requires an **OVER(PARTITION BEST)** clause.

### Syntax

```
MAPKEYS (VMap-data)
```

### Arguments

#### **VMap-data**

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

#### **max\_key\_length**

In a `__raw__` column, specifies the maximum length of keys that the function can return. Keys that are longer than `max_key_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

### Examples

#### **Determine Number of Virtual Columns in Map Data**

This example shows how to create a query, using an **over(PARTITION BEST)** clause with a flex table, `darkdata` to find the number of virtual column in the map data. The table is populated with JSON tweet data.

```
=> SELECT COUNT(keys) FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
count

 550
(1 row)
```

#### **Query Ordered List of All Virtual Columns in the Map**

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
keys

contributors
coordinates
created_at
delete.status.id
delete.status.id_str
delete.status.user_id
delete.status.user_id_str
entities.hashtags
entities.media
entities.urls
entities.user_mentions
favorited
geo
id
.
.
.
user.statuses_count
user.time_zone
user.url
user.utc_offset
user.verified
(125 rows)
```

### Specify the Maximum Length of Keys that MAPKEYS Can Return

```
=> SELECT MAPKEYS(__raw__ USING PARAMETERS max_key_length=100000) OVER() FROM mapper;
keys

five_Map
four
one
six
three_Array
two
(6 rows)
```

See also

### MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an **OVER(PARTITION BEST)** clause.

Syntax

```
MAPKEYSINFO (VMap-data)
```

Arguments

***VMap-data***

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

### **max\_key\_length**

In a `__raw__` column, determines the maximum length of keys that the function can return. Keys that are longer than `max_key_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

Returns

This function is a superset of the [MAPKEYS\(\)](#) function. It returns the following information about each virtual column:

Column	Description
<code>keys</code>	The virtual column names in the raw data.
<code>length</code>	The data length of the key name, which can differ from the actual string length.
<code>type_oid</code>	The OID type into which the value should be converted. Currently, the type is always <code>116</code> for a <code>LONG VARCHAR</code> , or <code>199</code> for a nested map that is stored as a <code>LONG VARBINARY</code> .
<code>row_num</code>	The number of rows in which the key was found.
<code>field_num</code>	The field number in which the key exists.

Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYSINFO(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
 keys | length | type_oid | row_num | field_num
-----+-----+-----+-----+-----
contributors | 0 | 116 | 1 | 0
coordinates | 0 | 116 | 1 | 1
created_at | 30 | 116 | 1 | 2
entities.hashtags | 93 | 199 | 1 | 3
entities.media | 772 | 199 | 1 | 4
entities.urls | 16 | 199 | 1 | 5
entities.user_mentions | 16 | 199 | 1 | 6
favorited | 1 | 116 | 1 | 7
geo | 0 | 116 | 1 | 8
id | 18 | 116 | 1 | 9
id_str | 18 | 116 | 1 | 10
.
.
.
delete.status.id | 18 | 116 | 11 | 0
delete.status.id_str | 18 | 116 | 11 | 1
delete.status.user_id | 9 | 116 | 11 | 2
delete.status.user_id_str | 9 | 116 | 11 | 3
delete.status.id | 18 | 116 | 12 | 0
delete.status.id_str | 18 | 116 | 12 | 1
delete.status.user_id | 9 | 116 | 12 | 2
delete.status.user_id_str | 9 | 116 | 12 | 3
(550 rows)
```

### **Specify the Maximum Length of Keys that MAPKEYSINFO Can Return**

```
=> SELECT MAPKEYSINFO(__raw__ USING PARAMETERS max_key_length=100000) OVER() FROM mapper;
keys

five_Map
four
one
six
three_Array
two
(6 rows)
```

## MAPLOOKUP

Returns single-key values from VMAP data. This scalar function returns a **LONG VARCHAR** , with values, or **NULL** if the virtual column does not have a value.

Using `maplookup` is case insensitive to virtual column names. To avoid loading same-name values, set the `fjsonparser` parser `reject_on_duplicate` parameter to `true` when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the `fjsonparser` or `favroparser` parsers and its `flatten-arrays` argument. See [JSON data](#) and the [FJSONPARSER](#) reference.

For information about using `maplookup()` to access nested JSON data, see [Querying nested data](#) .

## Syntax

```
MAPLOOKUP (VMap-data, 'virtual-column-name' [USING PARAMETERS [case_sensitive={false | true}] [, buffer_size=n]])
```

## Parameters

### **VMap-data**

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

### **virtual-column-name**

The name of the virtual column whose values this function returns.

### **buffer\_size**

[Optional parameter] Specifies the maximum length (in bytes) of each value returned for `virtual-column-name` . To return all values for `virtual-column-name` , specify a `buffer_size` equal to or greater than ( `=>` ) the number of bytes for any returned value. Any returned values greater in length than `buffer_size` are rejected.

**Default:** 0 (No limit on `buffer_size` )

### **case\_sensitive**

[Optional parameter]

Specifies whether to return values for `virtual-column-name` if keys with different cases exist.

Example:

```
(... USING PARAMETERS case_sensitive=true)
```

**Default:** `false`

## Examples

This example returns the values of one virtual column, `user.location` :

```
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata ORDER BY 1;
maplookup

Chile
Nesnia
Uptown
.
.
chicago
(12 rows)
```

## Using maplookup buffer\_size

Use the `buffer_size=` parameter to indicate the maximum length of any value that maplookup returns for the virtual column you specify. If none of the returned key values can be greater than `n` bytes, use this parameter to allocate `n` bytes as the `buffer_size` .

For the next example, save this JSON data to a file, `simple_name.json` :

```
{
 "name": "sierra",
 "age": "63",
 "eyes": "brown",
 "weapon": "doggie"
}
{
 "name": "janis",
 "age": "10",
 "eyes": "blue",
 "weapon": "humor"
}
{
 "name": "ben",
 "age": "43",
 "eyes": "blue",
 "weapon": "sword"
}
{
 "name": "jen",
 "age": "38",
 "eyes": "green",
 "weapon": "shopping"
}
```

1. Create a flex table, `logs` .
2. Load the `simple_name.json` data into `logs` , using the `fjsonparser` . Specify the `flatten_arrays` option as `True` :

```
=> COPY logs FROM '/home/dbadmin/data/simple_name.json'
PARSER fjsonparser(flatten_arrays=True);
```

3. Use `maplookup` with `buffer_size=0` for the `logs` table `name` key. This query returns all of the values:

```
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=0) FROM logs;
MapLookup

sierra
ben
janis
jen
(4 rows)
```

4. Next, call `maplookup()` three times, specifying the `buffer_size` parameter as 3, 5, and 6, respectively. Now, `maplookup()` returns values with a byte length less than or equal to (`<=`) `buffer_size` :

```
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=3) FROM logs;
MapLookup

ben

jen
(4 rows)
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=5) FROM logs;
MapLookup

janis
jen
ben
(4 rows)
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=6) FROM logs;
MapLookup

sierra
janis
jen
ben
(4 rows)
```

### Disambiguate Empty Output Rows

This example shows how to interpret empty rows. Using `maplookup` without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a `user.location` key has:

- A non-NULL value
- A `NULL` value
- No value

```
=> SELECT MAPLOOKUP(__row__, 'user.location') FROM darkdata;
maplookup

(12 rows)
```

To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a `NULL` or other value, or `f` for no value.

The following example output using both functions lists rows with `NULL` or a name value as `t`, and rows with no value as `f`:

```
=> SELECT MAPLOOKUP(__row__, 'user.location'), MAPCONTAINSKEY(__row__, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
-----+-----
 | t
 | t
 | t
 | t
Chile | t
Nesnia | t
Uptown | t
chicago | t
 | f >>>>>>>>>No value
 | f >>>>>>>>>No value
 | f >>>>>>>>>No value
 | f >>>>>>>>>No value
(12 rows)
```

### Check for Case-Sensitive Virtual Columns

You can use `maplookup()` with the `case_sensitive` parameter to return results when key names with different cases exist.

1. Save the following sample content as a JSON file. This example saves the file as `repeated_key_name.json`:

```
{
 "test": "lower1"
}
{
 "TEST": "upper1"
}
{
 "TEst": "half1"
}
{
 "test": "lower2",
 "TEst": "half2"
}
{
 "TEST": "upper2",
 "TEst": "half3"
}
{
 "test": "lower3",
 "TEST": "upper3"
}
{
 "TEst": "half4",
 "test": "lower4",
 "TEST": "upper4"
}
{
 "TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTesttest": "1",
 "TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTesttestTest12345": "2"
}
```

2. Create a flex table, `dupe`, and load the JSON file:

```

=> CREATE FLEX TABLE dupe();
CREATE TABLE
dbt=> COPY dupe FROM '/home/release/KData/repeated_key_name.json' parser fjsonparser();
Rows Loaded

 8
(1 row)

```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPPUT

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added. Keys must be set using the auxiliary function [SetMapKeys\(\)](#) , and can only be constant strings. If the VMap has any of the new input keys, then the original values are replaced by the new ones.

Syntax

```
MAPPUT (VMap-data, value[...]) USING PARAMETERS keys=SetMapKeys('key[,...]')
```

Arguments

### **VMap-data**

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#).
- Other database content

### **value [...]**

One or more values to add to the VMap specified in **VMap-data** .

Parameters

### **keys**

The result of [SetMapKeys\(\)](#) . [SetMapKeys\(\)](#) takes one or more constant string arguments.

The following example shows how to create a flex table and use COPY to enter some basic JSON data. After creating a second flex table, insert the new VMap results from [mapput\(\)](#) , with additional key/value pairs.

1. Create sample table:

```

=> CREATE FLEX TABLE vmapdata1();
CREATE TABLE

```

2. Load sample JSON data from STDIN:

```

=> COPY vmapdata1 FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"aaa": 1, "bbb": 2, "ccc": 3}
>> \.

```

3. Create another flex table and use the function to insert data into it: `=> CREATE FLEX TABLE vmapdata2(); => INSERT INTO vmapdata2 SELECT MAPPUT(__raw__, '7','8','9' using parameters keys=SetMapKeys('xxx','yyy','zzz')) from vmapdata1;`
4. View the difference between the original and the new flex tables:

```

=> SELECT MAPTOSTRING(__raw__) FROM vmapdata1;
 maptostring

{
 "aaa" : "1",
 "bbb" : "2",
 "ccc" : "3"
}
(1 row)

=> SELECT MAPTOSTRING(__raw__) from vmapdata2;
 maptostring

{
 "mapput" : {
 "aaa" : "1",
 "bbb" : "2",
 "ccc" : "3",
 "xxx" : "7",
 "yyy" : "8",
 "zzz" : "9"
 }
}

```

- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

### Syntax

```
MAPSIZE (VMap-data)
```

### Arguments

#### **VMap-data**

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

### Examples

This example shows the returned sizes from the number of keys in the flex table `darkmountain` :

```
=> SELECT MAPSIZE(__raw__) FROM darkmountain;
mapsize

 3
 4
 4
 4
 4
(5 rows)
```

See also

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPTOSTRING

Recursively builds a string representation of VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a LONG VARCHAR format. You can use MAPTOSTRING to see how map data is nested before querying virtual columns with [MAPVALUES](#).

Syntax

```
MAPTOSTRING (VMap-data [USING PARAMETERS param=value])
```

Arguments

### ***VMap-data***

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

Parameters

### **canonical\_json**

Boolean, whether to produce canonical JSON format, using the first instance of any duplicate keys in the map data. If false, the function returns duplicate keys and their values.

**Default:** true

Examples

The following example uses this table definition and sample data:

```
=> CREATE FLEX TABLE darkdata();
CREATE TABLE

=> COPY darkdata FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa\bbb"}
>> \.
```

Calling MAPTOSTRING with the default value of `canonical_json` returns only the first instance of the duplicate key:

```
=> SELECT MAPTOSTRING (__raw__) FROM darkdata;
 maptostring
```

```

{
 "AAA" : "3",
 "aaa" : "1",
 "bbb" : "aaa\"bbb"
}
(1 row)
```

With `canonical_json` set to false, the function returns all of the keys, including duplicates:

```
=> SELECT MAPTOSTRING(__raw__ using parameters canonical_json=false) FROM darkdata;
 maptostring
```

```

{
 "aaa": "1",
 "aaa": "2",
 "AAA": "3",
 "bbb": "aaa\"bbb"
}
(1 row)
```

See also

- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPVALUES

Returns a string representation of the top-level values from a VMap. This transform function requires an `OVER()` clause.

Syntax

```
MAPVALUES (VMap-data)
```

Arguments

### ***VMap-data***

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table
- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

### ***max\_value\_length***

In a `__raw__` column, specifies the maximum length of values the function can return. Values that are larger than `max_value_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K.

Examples

The following example shows how to query a `darkmountain` flex table, using an `over()` clause (in this case, the `over(PARTITION BEST)` clause) with `mapvalues()` .

```
=> SELECT * FROM (SELECT MAPVALUES(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
 values

29029
34.1
Everest
mountain
29029
15.4
Mt St Helens
volcano
17000
12.2
Denali
mountain
14000
22.8
Kilimanjaro
mountain
50.6
Mt Washington
mountain
(19 rows)
```

### Specify the Maximum Length of Values that MAPVALUES Can Return

```
=> SELECT MAPVALUES(__raw__ USING PARAMETERS max_value_length=100000) OVER() FROM mapper;
 keys

five_Map
four
one
six
three_Array
two
(6 rows)
```

See also

- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVERSION](#)

### MAPVERSION

Returns the version or invalidity of any map data. This scalar function returns the map version (such as **1** ) or **-1** , if the map data is invalid.

Syntax

```
MAPVERSION (VMap-data)
```

Arguments

#### **VMap-data**

Any VMap data. The VMap can exist as:

- The `__raw__` column of a flex table

- Data returned from a map function such as [MAPLOOKUP](#)
- Other database content

## Examples

The following example shows how to use `mapversion()` with the `darkmountain` flex table, returning `mapversion 1` for the flex table map data:

```
=> SELECT MAPVERSION(__raw__) FROM darkmountain;
mapversion

 1
 1
 1
 1
 1
(5 rows)
```

## See also

## Formatting functions

Formatting functions provide a powerful tool set for converting various data types (DATE/TIME, INTEGER, FLOATING POINT) to formatted strings and for converting from formatted strings to specific data types.

### In this section

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)
- [TO\\_BITSTRING](#)
- [TO\\_CHAR](#)
- [TO\\_DATE](#)
- [TO\\_HEX](#)
- [TO\\_NUMBER](#)
- [TO\\_TIMESTAMP](#)
- [TO\\_TIMESTAMP\\_TZ](#)

### Template patterns for date/time formatting

In an output template string (for `TO_CHAR`), certain patterns are recognized and replaced with appropriately formatted data from the value to format. Any text that is not a template pattern is copied verbatim. Similarly, in an input template string (for anything other than `TO_CHAR`), template patterns identify the parts of the input data string to look at and the values to find there.

#### Note

Vertica uses the ISO 8601:2004 style for date/time fields in Vertica log files. For example:

```
2020-03-25 05:04:22.372 Init Session:0x7f8fcefec700-a000000013dcd4 [Txn] <INFO> Begin Txn: a000000013dcd4 'read role info'
```

Pattern	Description
---------	-------------

HH	Hour of day (00-23)
HH12	Hour of day (01-12)
HH24	Hour of day (00-23)
MI	Minute (00-59)
SS	Second (00-59)
MS	Millisecond (000-999)
US	Microsecond (000000-999999)
SSSS	Seconds past midnight (0-86399)
AM A.M. PM P.M.	Meridian indicator (uppercase)
am a.m. pm p.m.	Meridian indicator (lowercase)
Y YYYY	Year (4 and more digits) with comma
YYYY	Year (4 and more digits)
YYY	Last 3 digits of year
YY	Last 2 digits of year
Y	Last digit of year
IYYYY	ISO year (4 and more digits)
IYY	Last 3 digits of ISO year
IY	Last 2 digits of ISO year
I	Last digits of ISO year
BC B.C. AD A.D.	Era indicator (uppercase)
bc b.c. ad a.d.	Era indicator (lowercase)
MONTH	Full uppercase month name (blank-padded to 9 chars)
Month	Full mixed-case month name (blank-padded to 9 chars)
month	Full lowercase month name (blank-padded to 9 chars)
MON	Abbreviated uppercase month name (3 chars)
Mon	Abbreviated mixed-case month name (3 chars)
mon	Abbreviated lowercase month name (3 chars)
MM	Month number (01-12)
DAY	Full uppercase day name (blank-padded to 9 chars)

Day	Full mixed-case day name (blank-padded to 9 chars)
day	full lowercase day name (blank-padded to 9 chars)
DY	Abbreviated uppercase day name (3 chars)
Dy	Abbreviated mixed-case day name (3 chars)
dy	Abbreviated lowercase day name (3 chars)
DDD	Day of year (001-366)
DD	Day of month (01-31) for TIMESTAMP  <div style="background-color: #e1f5fe; padding: 5px;"> <p><b>Note</b> For INTERVAL, DD is day of year (001-366) because day of month is undefined.</p> </div>
D	Day of week (1-7; Sunday is 1)
W	Week of month (1-5) (The first week starts on the first day of the month.)
WW	Week number of year (1-53) (The first week starts on the first day of the year.)
IW	ISO week number of year (The first Thursday of the new year is in week 1.)
CC	Century (2 digits)
J	Julian Day (days since January 1, 4712 BC)
Q	Quarter
RM	Month in Roman numerals (I-XII; I=January) (uppercase)
rm	Month in Roman numerals (i-xii; i=January) (lowercase)
TZ	Time-zone name (uppercase)
tz	Time-zone name (lowercase)

#### Template pattern modifiers

Certain modifiers can be applied to any date/time template pattern to alter its behavior. For example, **FMMonth** is the **Month** pattern with the **FM** modifier.

Modifier	Description
<b>AM</b>	Time is before 12:00
<b>AT</b>	Ignored
<b>JULIAN</b> , <b>JD</b> , <b>J</b>	Next field is Julian Day

<b>FM prefix</b>	Fill mode (suppress padding blanks and zeros)  For example: <b>FMMonth</b>  <b>Note:</b> The FM modifier suppresses leading zeros and trailing blanks that would otherwise be added to make the output of a pattern fixed width.
<b>FX prefix</b>	Fixed format global option  For example : <b>FX Month DD Day</b>
<b>ON</b>	Ignored
<b>PM</b>	Time is on or after 12:00
<b>T</b>	Next field is time
<b>TH suffix</b>	Uppercase ordinal number suffix  For example: <b>DDTH</b>
<b>th suffix</b>	Lowercase ordinal number suffix  For example: <b>DDth</b>
<b>TM prefix</b>	Translation mode (print localized day and month names based on lc_messages). For example: <b>TMMonth</b>

#### Examples

Use TO\_TIMESTAMP to convert an expression using the pattern '**YYY MON**' :

```
=> SELECT TO_TIMESTAMP('2017 JUN', 'YYYY MON');
 TO_TIMESTAMP

2017-06-01 00:00:00
(1 row)
```

Use TO\_DATE to convert an expression using the pattern '**YYY-MMDD**' :

```
=> SELECT TO_DATE('2017-1231', 'YYYY-MMDD');
 TO_DATE

2017-12-31
(1 row)
```

#### Template patterns for numeric formatting

Pattern	Description
<b>9</b>	Value with the specified number of digits
<b>0</b>	Value with leading zeros
<b>.</b>	Decimal point
<b>,</b>	Group (thousand) separator
<b>PR</b>	Negative value in angle brackets

<b>S</b>	Sign anchored to number (uses locale)
<b>L</b>	Currency symbol (uses locale)
<b>D</b>	Decimal point (uses locale)
<b>G</b>	Group separator (uses locale)
<b>MI</b>	Minus sign in specified position (if number < 0)
<b>PL</b>	Plus sign in specified position (if number > 0)
<b>SG</b>	Plus/minus sign in specified position
<b>RN</b>	Roman numeral (input between 1 and 3999)
<b>TH/th</b>	Ordinal number suffix
<b>V</b>	Shift specified number of digits
<b>EEEE</b>	Scientific notation (not implemented yet)

#### Usage

- A sign formatted using SG, PL, or MI is not anchored to the number. For example:

```
=> SELECT to_char(-12, 'S9999'), to_char(-12, 'MI9999');
```

```
to_char | to_char
```

```
-----+-----
```

```
-12 | - 12
```

```
(1 row)
```

- TO\_CHAR(-12, 'S9999') produces '-12'
- TO\_CHAR(-12, 'MI9999') produces '- 12'
- 9 results in a value with the same number of digits as there are 9s. If a digit is not available it outputs a space.
- TH does not convert values less than zero and does not convert fractional numbers.
- V effectively multiplies the input values by  $10^n$ , where  $n$  is the number of digits following V. TO\_CHAR does not support the use of V combined with a decimal point—for example: **99.9V99** .

#### TO\_BITSTRING

Returns a VARCHAR that represents the given VARBINARY value in bitstring format. This function is the inverse of [BITSTRING\\_TO\\_BINARY](#).

#### Behavior type

[Immutable](#)

#### Syntax

```
TO_BITSTRING (expression)
```

#### Arguments

##### **expression**

The VARCHAR string to process.

#### Examples

```
=> SELECT TO_BITSTRING('ab'::BINARY(2));
```

```
to_bitstring
```

```

0110000101100010
```

```
(1 row)
```

```
=> SELECT TO_BITSTRING(HEX_TO_BINARY('0x10'));
```

```
to_bitstring
```

```

00010000
```

```
(1 row)
```

```
=> SELECT TO_BITSTRING(HEX_TO_BINARY('0xF0'));
```

```
to_bitstring
```

```

11110000
```

```
(1 row)
```

See also

[BITCOUNT](#)

[TO\\_CHAR](#)

Converts date/time and numeric values into text strings.

Behavior type

[Stable](#)

Syntax

```
TO_CHAR (expression [, pattern])
```

Parameters

**expression**

Specifies the value to convert, one of the following data types:

- [DOUBLE PRECISION](#)
- [INTEGER](#)
- [INTERVAL](#)
- [TIME/TIMETZ](#)
- [TIMESTAMP/TIMESTAMPTZ](#)

The following restrictions apply:

- TO\_CHAR does not support binary data types BINARY and VARBINARY
- TO\_CHAR does not support the use of V combined with a decimal point—for example, **99.9V99**

**pattern**

A CHAR or VARCHAR that specifies an output pattern string. See [Template patterns for date/time formatting](#).

Notes

- Vertica pads TO\_CHAR output with a leading space, so positive and negative values have the same length. To suppress padding, use the [FM prefix](#).
- TO\_CHAR accepts TIME and TIMETZ data types as inputs if you explicitly cast TIME to TIMESTAMP and TIMETZ to TIMESTAMPTZ.

```
=> SELECT TO_CHAR(TIME '14:34:06.4','HH12:MI am'), TO_CHAR(TIMETZ '14:34:06.4+6','HH12:MI am');
```

```
TO_CHAR | TO_CHAR
```

```
-----+-----
02:34 pm | 04:34 am
```

```
(1 row)
```

- You can extract the timezone hour from TIMETZ:

```
=> SELECT EXTRACT(timezone_hour FROM TIMETZ '10:30+13:30');
```

```
date_part
```

```

13
```

```
(1 row)
```

- Ordinary text is allowed in TO\_CHAR templates and is output literally. You can put a substring in double quotes to force it to be interpreted as literal text even if it contains pattern key words. In the following example, **YYYY** is replaced by the year data, but the Y in **Year** is not:

```
=> SELECT to_char(CURRENT_TIMESTAMP, 'Hello Year " YYYY');
```

```
to_char
```

```

Hello Year 2021
```

```
(1 row)
```

- TO\_CHAR uses different day-of-the-week numbering (see the [D](#) template pattern) than [EXTRACT](#).
- Given an INTERVAL type, TO\_CHAR formats **HH** and **HH12** as hours in a single day, while **HH24** can output hours exceeding a single day—for example, **>24** .
- To include a double quote ( " ) character in output, precede it with a double backslash ( \ ). This is necessary because the backslash already has a special meaning in a string constant. For example: `\\"YYYY Month\\"`
- When rounding, the last digit of the rounded representation is selected to be even if the number is exactly half way between the two.

#### Examples

TO_CHAR expression and pattern argument	Output
CURRENT_TIMESTAMP, 'Day, DD HH12:MI:SS'	Tuesday , 06 05:39:18
CURRENT_TIMESTAMP, 'FMDay, FMDD HH12:MI:SS'	Tuesday, 6 05:39:18
TIMETZ '14:34:06.4+6','HH12:MI am'	04:34 am
-0.1, '99.99'	-.10
-0.1, 'FM9.99'	-.1
0.1, '0.9'	0.1

'1999-12-25 11:31 EST'::TIMESTAMPPTZ	1999-12-25 11:31:00-05
'3 days 1000.333 secs'::INTERVAL	3 days 00:16:40.333

See also

[DATE\\_PART](#)

[TO\\_DATE](#)

Converts a string value to a DATE type.

Behavior type

[Stable](#)

Syntax

`TO_DATE ( expression , pattern )`

Parameters

***expression***

Specifies the string value to convert, either **CHAR** or **VARCHAR** .

***pattern***

A **CHAR** or **VARCHAR** that specifies an output pattern string. See:

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)

Input value considerations

**TO\_DATE** requires a **CHAR** or **VARCHAR** expression. For other input types, use **TO\_CHAR** to perform an explicit cast to a **CHAR** or **VARCHAR** before using this function.

Notes

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: `"\\\"YYYY Month\\\""`
- **TO\_TIMESTAMP** , **TO\_TIMESTAMP\_TZ** , and **TO\_DATE** skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
  - **TO\_TIMESTAMP**('2000 JUN', 'YYYY MON') is correct.
  - **TO\_TIMESTAMP**('2000 JUN', 'FXYYYY MON') returns an error, because **TO\_TIMESTAMP** expects one space only.
- The **YYYY** conversion from string to **TIMESTAMP** or **DATE** has a restriction if you use a year with more than four digits. You must use a non-digit character or template after **YYYY** , otherwise the year is always interpreted as four digits. For example, given the following arguments, **TO\_DATE** interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131','YYYYMMDD');
TO_DATE

2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
TO_DATE

20000-12-01
(1 row)
```

- In conversions from string to **TIMESTAMP** or **DATE** , the CC field is ignored if there is a **YYY**, **YYYY** or **Y,YYY** field. If **CC** is used with **YY** or **Y**, then the year is computed as  $(CC-1)*100+YY$ .

Examples

```
=> SELECT TO_DATE('13 Feb 2000', 'DD Mon YYYY');
to_date

2000-02-13
(1 row)
```

See also

[Date/time functions](#)

**TO\_HEX**

Returns a **VARCHAR** or **VARBINARY** representing the hexadecimal equivalent of a number. This function is the inverse of [HEX\\_TO\\_BINARY](#).

Behavior type

[Immutable](#)

Syntax

```
TO_HEX (number)
```

Arguments

**number**

An [INTEGER](#) or [VARBINARY](#) value to convert to hexadecimal. If you supply a **VARBINARY** argument, the function's return value is not preceded by **0x** .

Examples

```
=> SELECT TO_HEX(123456789);
TO_HEX

75bcd15
(1 row)
```

For VARBINARY inputs, the returned value is not preceded by 0x . For example:

```
=> SELECT TO_HEX('ab'::binary(2));
TO_HEX

6162
(1 row)
```

## TO\_NUMBER

Converts a string value to DOUBLE PRECISION.

Behavior type

[Stable](#)

Syntax

```
TO_NUMBER (expression, [pattern])
```

Parameters

### *expression*

Specifies the string value to convert, either CHAR or VARCHAR.

### *pattern*

A string value, either CHAR or VARCHAR, that specifies an output pattern string using one of the supported [Template patterns for numeric formatting](#). If you omit this parameter, **TO\_NUMBER** returns a floating point.

Notes

To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: `"\\\"YYYY Month\\\""`

### Note

To convert a date string to a numeric value, use the appropriate [date/time function](#), such as [EXTRACT](#).

Examples

```
=> SELECT TO_NUMBER('MCML', 'rn');
TO_NUMBER

1950
(1 row)
```

It the *pattern* parameter is omitted, the function returns a floating point. For example:

```
=> SELECT TO_NUMBER('-123.456e-01');
TO_NUMBER

-12.3456
```

## TO\_TIMESTAMP

Converts a string value or a UNIX/POSIX epoch value to a **TIMESTAMP** type.

Behavior type

[Stable](#)

Syntax

```
TO_TIMESTAMP ({ expression, pattern } | unix-epoch)
```

Parameters

### *expression*

Specifies the string value to convert, of type CHAR or VARCHAR.

### *pattern*

A CHAR or VARCHAR that specifies an output pattern string. See:

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)

### unix-epoch

DOUBLE PRECISION value that specifies some number of seconds elapsed since midnight UTC of January 1, 1970, excluding leap seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.

### Notes

- Millisecond (MS) and microsecond (US) values in a conversion from string to **TIMESTAMP** are used as part of the seconds after the decimal point. For example **TO\_TIMESTAMP('12:3', 'SS:MS')** is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format **SS:MS**, the input values **12:3**, **12:30**, and **12:300** specify the same number of milliseconds. To get three milliseconds, use **12:003**, which the conversion counts as **12 + 0.003 = 12.003** seconds.

Here is a more complex example: **TO\_TIMESTAMP('15:12:02.020.001230', 'HH:MI:SS.MS.US')** is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: **"\\\"YYYY Month\\\""**
- **TO\_TIMESTAMP**, **TO\_TIMESTAMP\_TZ**, and **TO\_DATE** skip multiple blank spaces in the input string if the **FX** option is not used. **FX** must be specified as the first item in the template. For example:
  - **TO\_TIMESTAMP('2000 JUN', 'YYYY MON')** is correct.
  - **TO\_TIMESTAMP('2000 JUN', 'FXYYYY MON')** returns an error, because **TO\_TIMESTAMP** expects one space only.
- The **YYYY** conversion from string to **TIMESTAMP** or **DATE** has a restriction if you use a year with more than four digits. You must use a non-digit character or template after **YYYY**, otherwise the year is always interpreted as four digits. For example, given the following arguments, **TO\_DATE** interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131','YYYYMMDD');
TO_DATE

2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
TO_DATE

20000-12-01
(1 row)
```

- In conversions from string to **TIMESTAMP** or **DATE**, the **CC** field is ignored if there is a **YYY**, **YYYY** or **Y,YYY** field. If **CC** is used with **YY** or **Y**, then the year is computed as  $(CC-1)*100+YY$ .

### Examples

```
=> SELECT TO_TIMESTAMP('13 Feb 2009', 'DD Mon YYYY');
TO_TIMESTAMP

1200-02-13 00:00:00
(1 row)
=> SELECT TO_TIMESTAMP(200120400);
TO_TIMESTAMP

1976-05-05 01:00:00
(1 row)
```

See also

[Date/time functions](#)

**TO\_TIMESTAMP\_TZ**

Converts a string value or a UNIX/POSIX epoch value to a **TIMESTAMP WITH TIME ZONE** type.

Behavior type

[Immutable](#) if single argument form, [Stable](#) otherwise.

Syntax

TO\_TIMESTAMP\_TZ ( { *expression, pattern* } | *unix-epoch* )

## Parameters

### *expression*

Specifies the string value to convert, of type CHAR or VARCHAR.

### *pattern*

A CHAR or VARCHAR that specifies an output pattern string. See:

- [Template patterns for date/time formatting](#)
- [Template patterns for numeric formatting](#)

### *unix-epoch*

A DOUBLE PRECISION value that specifies some number of seconds elapsed since midnight UTC of January 1, 1970, excluding leap seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.

## Notes

- Millisecond (MS) and microsecond (US) values in a conversion from string to **TIMESTAMP** are used as part of the seconds after the decimal point. For example **TO\_TIMESTAMP('12:3', 'SS:MS')** is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format **SS:MS**, the input values **12:3**, **12:30**, and **12:300** specify the same number of milliseconds. To get three milliseconds, use **12:003**, which the conversion counts as **12 + 0.003 = 12.003** seconds. Here is a more complex example: **TO\_TIMESTAMP('15:12:02.020.001230', 'HH:MI:SS.MS.US')** is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.
- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: **"\\\"YYYY Month\\\""**
- **TO\_TIMESTAMP**, **TO\_TIMESTAMP\_TZ**, and **TO\_DATE** skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
  - **TO\_TIMESTAMP('2000 JUN', 'YYYY MON')** is correct.
  - **TO\_TIMESTAMP('2000 JUN', 'FXYYYY MON')** returns an error, because **TO\_TIMESTAMP** expects one space only.
- The **YYYY** conversion from string to **TIMESTAMP** or **DATE** has a restriction if you use a year with more than four digits. You must use a non-digit character or template after **YYYY**, otherwise the year is always interpreted as four digits. For example, given the following arguments, **TO\_DATE** interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131','YYYYMMDD');
TO_DATE

2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
TO_DATE

20000-12-01
(1 row)
```

- In conversions from string to **TIMESTAMP** or **DATE**, the CC field is ignored if there is a **YYY**, **YYYY** or **Y,YYY** field. If **CC** is used with **YY** or **Y**, then the year is computed as  $(CC-1)*100+YY$ .

## Examples

```
=> SELECT TO_TIMESTAMP_TZ('13 Feb 2009', 'DD Mon YYYY');
TO_TIMESTAMP_TZ

1200-02-13 00:00:00-05
(1 row)

=> SELECT TO_TIMESTAMP_TZ(200120400);
TO_TIMESTAMP_TZ

1976-05-05 01:00:00-04
(1 row)
```

## [Date/time functions](#)

### Geospatial functions

Geospatial functions manipulate complex two-dimensional spatial objects and store them in a database according to the Open Geospatial Consortium (OGC) standards.

#### Function naming conventions

The geospatial functions use the following naming conventions:

- Most ST\_ *function-name* functions are compliant with the latest OGC standard OGC SFA-SQL version 1.2.1 (reference number is OGC 06-104r4, date: 2010-08-04). Currently, some ST\_ *function-name* functions may not support all data types. Each function page contains details about the supported data types.

#### Note

Some functions, such as ST\_GeomFromText, are based on previous versions of the standard.

- The STV\_ *function-name* functions are unique to Vertica and not compliant with OGC standards. Each function page explains its functionality in detail.

#### Verifying spatial objects validity

Many spatial functions do not validate their parameters. If you pass an invalid spatial object to an ST\_ or STV\_ function, the function might return an error or produce incorrect results.

To avoid this issue, Vertica recommends that you first run ST\_IsValid on all spatial objects to validate the parameters. If your object is not valid, run STV\_IsValidReason to get information about the location of the invalidity.

## ST\_Area

Calculates the area of a spatial object.

The units are:

- GEOMETRY objects: spatial reference system identifier (SRID) units
- GEOGRAPHY objects: square meters

Behavior type

[Immutable](#)

Syntax

```
ST_Area(g)
```

Arguments

***g***

Spatial object for which you want to calculate the area, type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

### Examples

The following examples show how to use ST\_Area.

Calculate the area of a polygon:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((0 0,1 0,1 1,0 1,0 0))');
ST_Area

 1
(1 row)
```

Calculate the area of a multipolygon:

```
=> SELECT ST_Area(ST_GeomFromText('MultiPolygon(((0 0,1 0,1 1,0 1,0 0)),
((2 2,2 3,4 6,3 3,2 2))))');
ST_Area

 3
(1 row)
```

Suppose the polygon has a hole, as in the following figure.

Calculate the area, excluding the area of the hole:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((2 2,5 5,8 2,2 2),
(4 3,5 4,6 3,4 3))))');
ST_Area

 8
(1 row)
```

Calculate the area of a geometry collection:

```
=> SELECT ST_Area(ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((20.5 20.45,
20.51 20.52,20.69 20.32,20.5 20.45)),POLYGON((10 20,30 40,25 50,10 20))))');
ST_Area

150.0073
(1 row)
```

Calculate the area of a geography object:

```
=> SELECT ST_Area(ST_GeographyFromText('POLYGON((20.5 20.45,20.51 20.52,
20.69 20.32,20.5 20.45))'));
ST_Area

84627437.116037
(1 row)
```

## ST\_AsBinary

Creates the Well-Known Binary (WKB) representation of a spatial object. Use this function when you need to convert an object to binary form for porting spatial data to or from other applications.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_AsBinary(g)
```

Arguments

**g**

Spatial object for which you want the WKB, type GEOMETRY or GEOGRAPHY

Returns

LONG VARBINARY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following example shows how to use ST\_AsBinary.

Retrieve WKB and WKT representations:

```

=> CREATE TABLE locations (id INTEGER, name VARCHAR(100), geom1 GEOMETRY(800), geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
 (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG VARCHAR (800),
 geom2 AS ST_GeographyFromText(geom2x))
 FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(2 3)|
>> 2|LINESTRING(2 4,1 5)|
>> 3||POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09 45.25,-70.96 43.27))
>> \.
=> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;
id | ST_AsText | ST_AsText
-----+-----
 1 | POINT (2 3) |
 2 | LINESTRING (2 4, 1 5) |
 3 | | POLYGON ((-70.96 43.27, -70.67 42.95, -66.9 44.74, -67.81 46.08, -67.81 47.2, -69.22 47.43, -71.09 45.25, -70.96 43.27))
=> SELECT id, ST_AsBinary(geom1),ST_AsBinary(geom2) FROM locations ORDER BY id ASC;
.
.
.
(3 rows)

```

Calculate the length of a WKB using the Vertica SQL function [LENGTH](#):

```

=> SELECT LENGTH(ST_AsBinary(St_GeomFromText('POLYGON ((-1 2, 0 3, 1 2,
 0 1, -1 2)))));
LENGTH

 93
(1 row)

```

See also

[ST\\_AsText](#)

ST\_AsText

Creates the Well-Known Text (WKT) representation of a spatial object. Use this function when you need to specify a spatial object in ASCII form.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT string in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_AsText(g)
```

Arguments

***g***

Spatial object for which you want the WKT string, type GEOMETRY or GEOGRAPHY

Returns

LONG VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes

Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

## Examples

The following example shows how to use ST\_AsText.

Retrieve WKB and WKT representations:

```
=> CREATE TABLE locations (id INTEGER, name VARCHAR(100), geom1 GEOMETRY(800),
 geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
 (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG VARCHAR (800),
 geom2 AS ST_GeographyFromText(geom2x))
 FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(2 3)|
>> 2|LINESTRING(2 4,1 5)|
>> 3||POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09 45.25,-70.96 43.27))
>> \.
=> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;
id | ST_AsText | ST_AsText
-----+-----+-----
 1 | POINT (2 3) |
 2 | LINESTRING (2 4, 1 5) |
 3 | | POLYGON ((-70.96 43.27, -70.67 42.95, -66.9 44.74, -67.81 46.08, -67.81 47.2, -69.22 47.43, -71.09 45.25, -70.96 43.27))
(3 rows)
```

Calculate the length of a WKT using the Vertica SQL function [LENGTH](#):

```
=> SELECT LENGTH(ST_AsText(ST_GeomFromText('POLYGON ((-1 2, 0 3, 1 2,
 0 1, -1 2)))));
LENGTH

 37
(1 row)
```

See also

- [ST\\_AsBinary](#)

## ST\_Boundary

Calculates the boundary of the specified GEOMETRY object. An object's boundary is the set of points that define the limit of the object.

For a linestring, the boundary is the start and end points. For a polygon, the boundary is a linestring that begins and ends at the same point.

Behavior type

[Immutable](#)

Syntax

```
ST_Boundary(g)
```

Arguments

**g**

Spatial object for which you want the boundary, type GEOMETRY

Returns

## GEOMETRY

### Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

### Examples

The following examples show how to use ST\_Boundary.

Returns a linestring that represents the boundary:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((-1 -1,2 2,
 0 1,-1 -1)'))));
ST_AsText

LINESTRING(-1 -1, 2 2, 0 1, -1 -1)
(1 row)
```

Returns a multilinestring that contains the boundaries of both polygons:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((2 2,5 5,8 2,2 2),
 (4 3,5 4,6 3,4 3)'))));
ST_AsText

MULTILINESTRING ((2 2, 5 5, 8 2, 2 2), (4 3, 5 4, 6 3, 4 3))
(1 row)
```

The boundary of a linestring is its start and end points:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText(
 'LINESTRING(1 1,2 2,3 3,4 4)'));
ST_AsText

MULTIPOINT (1 1, 4 4)
(1 row)
```

A closed linestring has no boundary because it has no start and end points:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText(
 'LINESTRING(1 1,2 2,3 3,4 4,1 1)'));
ST_AsText

MULTIPOINT EMPTY
(1 row)
```

### ST\_Buffer

Creates a GEOMETRY object greater than or equal to a specified distance from the boundary of a spatial object. The distance is measured in Cartesian coordinate units. ST\_Buffer does not accept a distance size greater than +1e15 or less than -1e15.

Behavior type

[Immutable](#)

Syntax

```
ST_Buffer(g, d)
```

Arguments

***g***

Spatial object for which you want to calculate the buffer, type GEOMETRY

***d***

Distance from the object in Cartesian coordinate units, type FLOAT

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Usage tips

- If you specify a positive distance, ST\_Buffer returns a polygon that represents the points within or equal to the distance outside the object. If you specify a negative distance, ST\_Buffer returns a polygon that represents the points within or equal to the distance inside the object.
- For points, multipoints, linestrings, and multilinestrings, if you specify a negative distance, ST\_Buffer returns an empty polygon.
- The Vertica Place version of ST\_Buffer returns the buffer as a polygon, so the buffer object has corners at its vertices. It does not contain rounded corners.

Examples

The following example shows how to use ST\_Buffer.

Returns a GEOMETRY object:

```
=> SELECT ST_AsText(ST_Buffer(ST_GeomFromText('POLYGON((0 1,1 4,4 3,0 1)'),1));
 ST_AsText

POLYGON ((-0.188847498856 -0.159920845081, -1.12155598386 0.649012935089, 0.290814745534 4.76344136152,
0.814758063466 5.02541302048, 4.95372324225 3.68665254814, 5.04124517538 2.45512549204, -0.188847498856 -0.159920845081))
(1 row)
```

ST\_Centroid

Calculates the geometric center—the centroid—of a spatial object. If points or linestrings or both are present in a geometry with polygons, only the polygons contribute to the calculation of the centroid. Similarly, if points are present with linestrings, the points do not contribute to the calculation of the centroid.

To calculate the centroid of a GEOGRAPHY object, see the examples for [STV\\_Geometry](#) and [STV\\_Geography](#).

Behavior type

[Immutable](#)

Syntax

ST\_Centroid( g )

Arguments

**g**

Spatial object for which you want to calculate the centroid, type GEOMETRY

Returns

GEOMETRY (POINT only)

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST\_Centroid.

Calculate the centroid for a polygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('POLYGON((-1 -1,2 2,-1 2,-1 -1))'));
 ST_AsText

POINT (-0 1)
(1 row)
```

Calculate the centroid for a multipolygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('MULTIPOLYGON(((1 0,2 1,2 0,1 0)),((-1 -1,2 2,-1 2,-1 -1))')));
 ST_AsText

POINT (0.166666666667 0.933333333333)
(1 row)
```

This figure shows the centroid for the multipolygon.

ST\_Contains

Determines if a spatial object is entirely inside another spatial object without existing only on its boundary. Both arguments must be the same spatial data type. Either specify two GEOMETRY objects or two GEOGRAPHY objects.

If an object such as a point or linestring only exists along a spatial object's boundary, then ST\_Contains returns false. The interior of a linestring is all the points on the linestring except the start and end points.

ST\_Contains( *g1* , *g2* ) is functionally equivalent to ST\_Within( *g2* , *g1* ) .

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Contains(g1 , g2
 [USING PARAMETERS spheroid={true | false}])
```

Arguments

***g1***

Spatial object, type GEOMETRY or GEOGRAPHY

***g2***

Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

**spheroid = {true | false}**

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

**Default** : False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	No	No
Linestring	Yes	Yes	No
Multilinestring	Yes	No	No
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	No
Linestring-Point	Yes	No
Polygon-Point	Yes	Yes
Multipolygon-Point	Yes	No

Examples

The following examples show how to use ST\_Contains.

The first polygon does not completely contain the second polygon:

```
=> SELECT ST_Contains(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2)'),
 ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3)'));
ST_Contains
```

```

f
(1 row)
```

If a point is on a linestring, but not on an end point:

```
=> SELECT ST_Contains(ST_GeomFromText('LINESTRING(20 20,30 30)'),
 ST_GeomFromText('POINT(25 25)');
ST_Contains
```

```

t
(1 row)
```

If a point is on the boundary of a polygon:

```
=> SELECT ST_Contains(ST_GeographyFromText('POLYGON((20 20,30 30,30 25,20 20)'),
 ST_GeographyFromText('POINT(20 20)');
ST_Contains
```

```

f
(1 row)
```

Two spatially equivalent polygons:

```
=> SELECT ST_Contains (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2)'),
 ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3)'));
ST_Contains
```

```

t
(1 row)
```

See also

- [ST\\_Overlaps](#)
- [ST\\_Within](#)

ST\_ConvexHull

Calculates the smallest convex GEOMETRY object that contains a GEOMETRY object.

Behavior type

[Immutable](#)

Syntax

```
ST_ConvexHull(g)
```

Arguments

***g***  
Spatial object for which you want the convex hull, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST\_ConvexHull.

For a pair of points in a geometry collection:

```
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(
POINT(1 1),POINT(0 0)'))));
ST_AsText

LINESTRING (1 1, 0 0)
(1 row)
```

For a geometry collection:

```
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(
 LINestring(2.5 3,-2 1.5), POLYGON((0 1,1 3,1 -2,0 1))))));
 ST_AsText
```

```
POLYGON ((1 -2, -2 1.5, 1 3, 2.5 3, 1 -2))
(1 row)
```

The solid lines represent the original geometry collection and the dashed lines represent the convex hull.

## ST\_Crosses

Determines if one GEOMETRY object spatially crosses another GEOMETRY object. If two objects touch only at a border, ST\_Crosses returns FALSE.

Two objects spatially cross when both of the following are true:

- The two objects have some, but not all, interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

Behavior type

[Immutable](#)

Syntax

```
ST_Crosses(g1, g2)
```

Arguments

***g1***

Spatial object, type GEOMETRY

***g2***

Spatial object, type GEOMETRY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST\_Crosses.

```
=> SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 3,1 4)'),
 ST_GeomFromText('LINESTRING(-1 4,1 3)'));
ST_Crosses

t
(1 row)
```

```
=> SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 1,1 2)'),
 ST_GeomFromText('POLYGON((1 1,0 -1,3 -1,2 1,1 1)'));
ST_Crosses

f
(1 row)
```

```
=> SELECT ST_Crosses(ST_GeomFromText('POINT(-1 4)'),
 ST_GeomFromText('LINESTRING(-1 4,1 3)'));
ST_Crosses

f
(1 row)
```

### ST\_Difference

Calculates the part of a spatial object that does not intersect with another spatial object.

Behavior type

[Immutable](#)

Syntax

```
ST_Difference(g1, g2)
```

Arguments

***g1***

Spatial object, type GEOMETRY

***g2***

Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST\_Difference.

Two overlapping linestrings:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 2)'),
 ST_GeomFromText('LINESTRING(0 1,0 2)'));
 ST_AsText

LINESTRING (0 0, 0 1)
(1 row)
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 3)'),
 ST_GeomFromText('LINESTRING(0 1,0 2)'));
 ST_AsText

MULTILINESTRING ((0 0, 0 1), (0 2, 0 3))
(1 row)
```

Two overlapping polygons:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((0 1,0 3,2 3,2 1,0 1))'),
 ST_GeomFromText('POLYGON((0 0,0 2,2 2,2 0,0 0)')));
 ST_AsText

POLYGON ((0 2, 0 3, 2 3, 2 2, 0 2))
(1 row)
```

Two non-intersecting polygons:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((1 1,1 3,3 3,3 1,
 1 1)'),ST_GeomFromText('POLYGON((1 5,1 7,-1 7,-1 5,1 5)'))));
 ST_AsText
```

```

POLYGON ((1 1, 1 3, 3 3, 3 1, 1 1))
(1 row)
```

## ST\_Disjoint

Determines if two GEOMETRY objects do not intersect or touch.

If ST\_Disjoint returns TRUE for a pair of GEOMETRY objects, ST\_Intersects returns FALSE for the same two objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Disjoint(g1, g2
 [USING PARAMETERS spheroid={true | false}])
```

Arguments

**g1**

Spatial object, type GEOMETRY

**g2**

Spatial object, type GEOMETRY

Parameters

**spheroid = {true | false}**

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

**Default** : False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

### Data Type

GEOGRAPHY (WGS84)

### Point-Point

No

### Linestring-Point

No

## Polygon-Point

Yes

## Multipolygon-Point

No

## Examples

The following examples show how to use ST\_Disjoint.

Two non-intersecting or touching polygons:

```
=> SELECT ST_Disjoint(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
 ST_GeomFromText('POLYGON((1 0, 1 1, 2 2, 1 0)'));
ST_Disjoint

t
(1 row)
```

Two intersecting linestrings:

```
=> SELECT ST_Disjoint(ST_GeomFromText('LINESTRING(-1 2,0 3)'),
 ST_GeomFromText('LINESTRING(0 2,-1 3)'));
ST_Disjoint

f
(1 row)
```

Two polygons touching at a single point:

```
=> SELECT ST_Disjoint(ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2)'),
 ST_GeomFromText('POLYGON((0 2, 1 1, 1 2, 0 2)'));
ST_Disjoint

f
(1 row)
```

See also

- [ST\\_Intersects](#)

## ST\_Distance

Calculates the shortest distance between two spatial objects. For GEOMETRY objects, the distance is measured in Cartesian coordinate units. For GEOGRAPHY objects, the distance is measured in meters.

Parameters **g1** and **g2** must be both GEOMETRY objects or both GEOGRAPHY objects.

Behavior type

[Immutable](#)

Syntax

```
ST_Distance(g1, g2)
 [USING PARAMETERS spheroid={ true | false }])
```

Arguments

**g1**

Spatial object, type GEOMETRY or GEOGRAPHY

**g2**

Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

**spheroid = { true | false }**

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

**Default** : False

Returns

## FLOAT

### Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	No
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

### Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	Yes
Linestring-Point	Yes	Yes
Multilinestring-Point	Yes	Yes
Polygon-Point	Yes	No
Multipoint-Point	Yes	Yes
Multipoint-Multilinestring	Yes	No
Multipolygon-Point	Yes	No

### Recommendations

Vertica recommends pruning invalid data before using ST\_Distance. Invalid geography values could return non-guaranteed results.

### Examples

The following examples show how to use ST\_Distance.

Distance between two polygons:

```
=> SELECT ST_Distance(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
 ST_GeomFromText('POLYGON((5 2,7 4,5 5,5 2)'));
ST_Distance

 3
(1 row)
```

Distance between a point and a linestring in meters:

```
=> SELECT ST_Distance(ST_GeographyFromText('POINT(31.75 31.25)'),
 ST_GeographyFromText('LINESTRING(32 32,32 35,40.5 35,32 35,32 32)'));
ST_Distance

86690.3950562969
(1 row)
```

## ST\_Envelope

Calculates the minimum bounding rectangle that contains the specified GEOMETRY object.

Behavior type

[Immutable](#)

Syntax

```
ST_Envelope(g)
```

Arguments

***g***

Spatial object for which you want to find the minimum bounding rectangle, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following example shows how to use ST\_Envelope.

Returns the minimum bounding rectangle:

```
=> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('POLYGON((0 0,1 1,2,2,2,2,3 0,1.5 -1.5,0 0)'))));
 ST_AsText
```

```
POLYGON ((0 -1.5, 3 -1.5, 3 2, 0 2, 0 -1.5))
```

```
(1 row)
```

## ST\_Equals

Determines if two spatial objects are spatially equivalent. The coordinates of the two objects and their WKT/WKB representations must match exactly for ST\_Equals to return TRUE.

The order of the points do not matter in determining spatial equivalence:

- LINESTRING(1 2, 4 3) equals LINESTRING(4 3, 1 2).
- POLYGON ((0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0)) equals POLYGON((1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0, 1 1)).

- MULTILINESTRING((1 2, 4 3),(0 0, -1 -4)) equals MULTILINESTRING((0 0, -1 -4),(1 2, 4 3)).

Coordinates are stored as FLOAT types. Thus, rounding errors are expected when importing Well-Known Text (WKT) values because the limitations of floating-point number representation.

**g1** and **g2** must both be GEOMETRY objects or both be GEOGRAPHY objects. Also, **g1** and **g2** cannot both be of type GeometryCollection.

Behavior type

[Immutable](#)

Syntax

```
ST_Equals(g1, g2)
```

Arguments

**g1**  
Spatial object to compare to **g2** , type GEOMETRY or GEOGRAPHY

**g2**  
Spatial object to compare to **g1** , type GEOMETRY or GEOGRAPHY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST\_Equals.

Two linestrings:

```
=> SELECT ST_Equals (ST_GeomFromText('LINESTRING(-1 2, 0 3)'),
 ST_GeomFromText('LINESTRING(0 3, -1 2)'));
ST_Equals

t
(1 row)
```

Two polygons:

```
=> SELECT ST_Equals (ST_GeographyFromText('POLYGON((43.22 42.21,40.3 39.88,
 42.1 50.03,43.22 42.21))'),ST_GeographyFromText('POLYGON((43.22 42.21,
 40.3 39.88,42.1 50.31,43.22 42.21))'));
ST_Equals

f
(1 row)
```

ST\_GeographyFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOGRAPHY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOGRAPHY object is a spatial object with coordinates (longitude, latitude) defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKT to ST\_GeographyFromText, the result is a spatial object whose size is greater than 10 MB, ST\_GeographyFromText returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT string in Section 7 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_GeographyFromText(wkt [USING PARAMETERS ignore_errors={'y'|'n'}])
```

Arguments

**wkt**

Well-Known Text (WKT) string of a GEOGRAPHY object, type LONG VARCHAR

**ignore\_errors**

(Optional) ST\_GeographyFromText returns the following, based on the parameters supplied:

- NULL—If **wkt** is invalid and **ignore\_errors = 'y'**.
- Error—If **wkt** is invalid and **ignore\_errors = 'n'** or is unspecified.

Returns

GEOGRAPHY

Supported data types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Examples

The following example shows how to use ST\_GeographyFromText.

Convert WKT into a GEOGRAPHY object:

```
=> CREATE TABLE wkt_ex (g GEOGRAPHY);
CREATE TABLE
=> INSERT INTO wkt_ex VALUES(ST_GeographyFromText('POLYGON((1 2,3 4,2 3,1 2))'));
OUTPUT

 1
(1 row)
```

ST\_GeographyFromWKB

Converts a Well-Known Binary (WKB) value into its corresponding GEOGRAPHY object. Use this function to convert a WKB into the format expected by Vertica Place functions.

A GEOGRAPHY object is a spatial object defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth. All calculations are in meters.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKB to ST\_GeographyFromWKB that results in a spatial object whose size is greater than 10 MB, ST\_GeographyFromWKB returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in Section 8 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_GeographyFromWKB(wkb [USING PARAMETERS ignore_errors='{y'|'n'}])
```

Arguments

**wkb**

Well-Known Binary (WKB) value of a GEOGRAPHY object, type LONG VARBINARY

**ignore\_errors**

(Optional) ST\_GeographyFromWKB returns the following, based on the parameters supplied:

- NULL—If **wkb** is invalid and **ignore\_errors** = 'y' .
- Error—If **wkb** is invalid and **ignore\_errors** = 'n' or is unspecified.

Returns

GEOGRAPHY

Supported data types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Examples

The following example shows how to use ST\_GeographyFromWKB.

Convert WKB into a GEOGRAPHY object:

```
=> CREATE TABLE wkb_ex (g GEOGRAPHY);
CREATE TABLE
=> INSERT INTO wkb_ex VALUES(ST_GeographyFromWKB(X'0103000000010000000 ...));
OUTPUT

 1
(1 row)
```

ST\_GeoHash

Returns a GeoHash in the shape of the specified geometry.

Behavior type

[Immutable](#)

Syntax

```
ST_GeoHash(SpatialObject [USING PARAMETERS numchars=n])
```

#### Arguments

##### **Spatial object**

A GEOMETRY or GEOGRAPHY spatial object. Inputs must be in polar coordinates ( $-180 \leq x \leq 180$  and  $-90 \leq y \leq 90$ ) for all points inside the given geometry.

##### ***n***

Specifies the length, in characters, of the returned GeoHash.

#### Returns

GEOHASH

#### Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

#### Examples

The following examples show how to use ST\_PointFromGeoHash.

Generate a full precision GeoHash for the specified geometry:

```
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'));
ST_GeoHash

kpf0rkn3zmcswks75010
(1 row)
```

Generate a GeoHash based on the first five characters of the specified geometry:

```
=> select ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)')USING PARAMETERS numchars=5);
ST_GeoHash

kpf0r
(1 row)
```

#### ST\_GeometryN

Returns the *n*<sup>th</sup> geometry within a geometry object.

If *n* is out of range of the index, then NULL is returned.

#### Behavior type

[Immutable](#)

#### Syntax

```
ST_GeometryN(g , n)
```

#### Arguments

##### ***g***

Spatial object of type GEOMETRY.

**n**

The geometry's index number, 1-based.

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST\_GeometryN.

Return the second geometry in a multipolygon:

```
=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT gid, ST_AsText(ST_GeometryN(geom, 2)) FROM multipolygon_geom;
gid | ST_AsText
-----+-----
 9 | POLYGON ((0 0, 0 5, 1 0, 0 0))
(1 row)
```

Return all the geometries within a multipolygon:

```

=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> CREATE TABLE series_numbers (numbs int);
CREATE TABLE
=> COPY series_numbers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> 4
>> 5
>> \.
=> SELECT numbs, ST_AsText(ST_GeometryN(geom, numbs))
 FROM multipolygon_geom, series_numbers
 WHERE ST_AsText(ST_GeometryN(geom, numbs)) IS NOT NULL
 ORDER BY numbs ASC;
numbs | ST_AsText
-----+-----
 1 | POLYGON ((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
 2 | POLYGON ((0 0, 0 5, 1 0, 0 0))
 3 | POLYGON ((0 2, 2 5, 4 5, 0 2))
(3 rows)

```

See also

[ST\\_NumGeometries](#)

[ST\\_GeometryType](#)

Determines the class of a spatial object.

Behavior type

[Immutable](#)

Syntax

```
ST_GeometryType(g)
```

Arguments

***g***

Spatial object for which you want the class, type GEOMETRY or GEOGRAPHY

Returns

VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes

Multipolygon	Yes	Yes
GeometryCollection	Yes	No

### Examples

The following example shows how to use ST\_GeometryType.

Returns spatial class:

```
=> SELECT ST_GeometryType(ST_GeomFromText('GEOMETRYCOLLECTION(LINESTRING(1 1,
 2 2), POLYGON((1 3,4 5,2 2,1 3)))));
 ST_GeometryType

ST_GeometryCollection
(1 row)
```

### ST\_GeomFromGeoHash

Returns a polygon in the shape of the specified GeoHash.

Behavior type

[Immutable](#)

Syntax

```
ST_GeomFromGeoHash(GeoHash)
```

Arguments

#### **GeoHash**

A valid GeoHash string of arbitrary length.

Returns

GEOGRAPHY

Examples

The following examples show how to use ST\_GeomFromGeoHash.

Converts a GeoHash string to a Geography object and back to a GeoHash

```
=> SELECT ST_GeoHash(ST_GeomFromGeoHash('vert1c9'));
 ST_GeoHash

vert1c9
(1 row)
```

Returns a polygon of the specified GeoHash and uses [ST\\_AsText](#) to convert the polygon, rectangle map tile, into Well-Known Text:

```
=> SELECT ST_AsText(ST_GeomFromGeoHash('drt3jj9n4dpcbcdef'));
 ST_AsText

POLYGON((-71.1459699298 42.3945346513, -71.1459699297 42.3945346513, -71.1459699297 42.3945346513, -71.1459699298 42.3945346513, -71.1459699298 42.3945346513))
(1 row)
```

Returns multiple polygons and their areas for the specified GeoHashes. The polygon for the high level GeoHash (1234) has a significant area, while the low level GeoHash (1234567890bcdefghjkmn) has an area of zero.

```
=> SELECT ST_Area(short) short_area, ST_AsText(short) short_WKT, ST_Area(long) long_area, ST_AsText(long) long_WKT from (SELECT
ST_GeomFromGeoHash('1234') short, ST_GeomFromGeoHash('1234567890bcdefhijkmn') long) as foo;
-[RECORD 1]-----
short_area | 24609762.8991076
short_WKT | POLYGON ((-122.34375 -88.2421875, -121.9921875 -88.2421875, -121.9921875 -88.06640625, -122.34375 -88.06640625, -122.34375 -
88.2421875))
long_area | 0
long_WKT | POLYGON ((-122.196077187 -88.2297377551, -122.196077187 -88.2297377551, -122.196077187 -88.2297377551, -122.196077187 -
88.2297377551, -122.196077187 -88.2297377551))
```

## ST\_GeomFromGeoJSON

Converts the geometry portion of a GeoJSON record in the [standard format](#) into a GEOMETRY object. This function returns an error when you provide a GeoJSON Feature or FeatureCollection object.

Behavior type

[Immutable](#)

Syntax

```
ST_GeomFromGeoJSON(geojson [, srid] [USING PARAMETERS param=value[,...]]);
```

Arguments

### **geojson**

String containing a GeoJSON GEOMETRY object, type LONG VARCHAR.

Vertica accepts the following GeoJSON key values:

- type
- coordinates
- geometries

Other key values are ignored.

### **srid**

Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER.

The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.

This argument is optional when not performing operations.

Parameters

### **ignore\_3d**

(Optional) Boolean, whether to silently remove 3D and higher-dimensional data from the returned GEOMETRY object or return an error, based on the following values:

- true: Removes 3D and higher-dimensional data from the returned GEOMETRY object.
- false (default): Returns an error when the GeoJSON contains 3D or higher-dimensional data.

### **ignore\_errors**

(Optional) Boolean, whether to ignore errors on invalid GeoJSON objects or return an error, based on the following values:

- true: Ignores errors during GeoJSON parsing and returns NULL.
- false (default): Returns an error if GeoJSON parsing fails.

#### Note

The **ignore\_errors** setting takes precedence over the **ignore\_3d** setting. For example, if **ignore\_errors** is set to true and **ignore\_3d** is set to false, the function returns NULL if a GeoJSON object contains 3D and higher-dimensional data.

Returns

GEOMETRY

Supported data types

- Point
- Multipoint
- Linestring

- Multilinestring
- Polygon
- Multipolygon
- GeometryCollection

## Examples

The following example shows how to use ST\_GeomFromGeoJSON.

### Validating a single record

The following example validates a ST\_GeomFromGeoJSON statement with [ST\\_IsValid](#). The statement includes the SRID 4326 to indicate that the point data type represents latitude and longitude coordinates, and sets `ignore_3d` to true to ignore the last value that represents the altitude:

```
=> SELECT ST_IsValid(ST_GeomFromGeoJSON('{"type":"Point","coordinates":[35.3606, 138.7274, 29032]}', 4326 USING PARAMETERS ignore_3d=true));
ST_IsValid

t
(1 row)
```

### Loading data into a table

The following example processes GeoJSON types from STDIN and stores them in a GEOMETRY data type table column:

1. Create a table named polygons that stores GEOMETRY spatial types:

```
=> CREATE TABLE polygons(geom GEOMETRY(1000));
CREATE TABLE
```

2. Use COPY to read supported GEOMETRY data types from STDIN and store them in an object named geom :

```
=> COPY polygons(geojson filler VARCHAR(1000), geom as ST_GeomFromGeoJSON(geojson)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> { "type": "Polygon", "coordinates": [[[100.0, 0.0], [101.0, 0.0], [101.0, 1.0], [100.0, 1.0], [100.0, 0.0]]] }
>> { "type": "Point", "coordinates": [1, 2] }
>> { "type": "Polygon", "coordinates": [[[1, 3], [3, 2], [1, 1], [3, 0], [1, 0], [1, 3]]] }
>> \.
```

3. Query the polygons table. The following example uses [ST\\_AsText](#) to return the geom object in its [Well-known text \(WKT\)](#) representation, and uses [ST\\_IsValid](#) to validate each object:

```
=> SELECT ST_AsText(geom), ST_IsValid(geom) FROM polygons;
 ST_AsText | ST_IsValid
-----+-----
POINT (1 2) | t
POLYGON ((1 3, 3 2, 1 1, 3 0, 1 0, 1 3)) | f
POLYGON ((100 0, 101 0, 101 1, 100 1, 100 0)) | t
(3 rows)
```

## ST\_GeomFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOMETRY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOMETRY object is a spatial object defined by the coordinates of a plane. Coordinates are expressed as points on a Cartesian plane ( $x, y$ ). SRID values of 0 to  $2^{32}-1$  are valid. SRID values outside of this range will generate an error.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKT to ST\_GeomFromText and the result is a spatial object whose size is greater than 10 MB, [ST\\_GeomFromText](#) returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT representation. See section 7 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

### Behavior type

[Immutable](#)

### Syntax

```
ST_GeomFromText(wkt [, srid] [USING PARAMETERS ignore_errors={'y'|'n'}])
```

### Arguments

**wkt**

Well-Known Text (WKT) string of a GEOMETRY object, type LONG VARCHAR.

**srid**

(Optional when not performing operations)

Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER.

The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.

**ignore\_errors**

(Optional) ST\_GeomFromText returns the following, based on parameters supplied:

- NULL—If **wkt** is invalid and **ignore\_errors** = 'y'.
- Error—If **wkt** is invalid and **ignore\_errors** = 'n' or is unspecified.

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Examples

The following example shows how to use ST\_GeomFromText.

Convert WKT into a GEOMETRY object:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((1 1,2 3,3 5,0 5,1 -2,0 0,1 1))));
ST_Area

 6
(1 row)
```

**ST\_GeomFromWKB**

Converts the Well-Known Binary (WKB) value to its corresponding GEOMETRY object. Use this function to convert a WKB into the format expected by many of the Vertica Place functions.

A GEOMETRY object is a spatial object with coordinates ( *x* , *y* ) defined in the Cartesian plane.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKB to **ST\_GeomFromWKB** and the result is a spatial object whose size is greater than 10 MB, **ST\_GeomFromWKB** returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in section 8 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior type

[Immutable](#)

Syntax

```
ST_GeomFromWKB(wkb[, srid] [USING PARAMETERS ignore_errors={ 'y'|'n' }])
```

## Arguments

### **wkb**

Well-Known Binary (WKB) value of a GEOMETRY object, type LONG VARBINARY

### **srid**

(Optional) Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER.

The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.

### **ignore\_errors**

(Optional) `ST_GeomFromWKB` returns the following, based on the parameters supplied:

- **NULL**—If `wkb` is invalid and `ignore_errors = 'y'` .
- **Error**—If `wkb` is invalid and `ignore_errors = 'n'` or is unspecified.

## Returns

GEOMETRY

## Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

## Examples

The following example shows how to use `ST_GeomFromWKB`.

Convert GEOMETRY into WKT:

```
=> CREATE TABLE t(g GEOMETRY);
CREATE TABLE
=> INSERT INTO t VALUES(
ST_GeomFromWKB(X'0103000000010000000400f
03f000000000000000f64ae1c7022db5440000000000f03f000000000000000000000000000000');
OUTPUT

1
(1 row)
=> SELECT ST_AsText(g) from t;
ST_AsText

POLYGON ((0 0, 1 0, 1e+23 1, 0 0))
(1 row)
```

## ST\_Intersection

Calculates the set of points shared by two GEOMETRY objects.

### Behavior type

[Immutable](#)

### Syntax

```
ST_Intersection(g1, g2)
```

## Arguments

**g1**

Spatial object, type GEOMETRY

**g2**

Spatial object, type GEOMETRY

## Returns

GEOMETRY

## Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

## Examples

The following examples show how to use ST\_Intersection.

Two polygons intersect at a single point:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,
 0 2))'),ST_GeomFromText('POLYGON((-1 2,0 0,-2 0,-1 2)'))));
 ST_AsText

POINT(0 0)
(1 row)
```

Two polygons:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((1 2,1 5,4 5,
 4 2,1 2)'), ST_GeomFromText('POLYGON((3 1,3 3,5 3,5 1,3 1)'))));
ST_AsText

POLYGON ((4 3, 4 2, 3 2, 3 3, 4 3))
(1 row)
```

Two non-intersecting linestrings:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('LINESTRING(1 1,1 3,3 3)'),
 ST_GeomFromText('LINESTRING(1 5,1 7,-1 7)'));
ST_AsText

GEOMETRYCOLLECTION EMPTY
(1 row)
```

## ST\_Intersects

Determines if two GEOMETRY or GEOGRAPHY objects intersect or touch at a single point. If ST\_Disjoint returns TRUE, ST\_Intersects returns FALSE for the same GEOMETRY or GEOGRAPHY objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Intersects(g1, g2
 [USING PARAMETERS bbox={true | false}, spheroid={true | false}])
```

Arguments

***g1***

Spatial object, type GEOMETRY

***g2***

Spatial object, type GEOMETRY

Parameters

**bbox = {true | false}**

Boolean. Intersects the bounding box of ***g1*** and ***g2*** .

**Default:** False

**spheroid = {true | false}**

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

**Default :** False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
-----------	----------	-------------------

<b>Point</b>	Yes	Yes
<b>Multipoint</b>	Yes	No
<b>Linestring</b>	Yes	No
<b>Multilinestring</b>	Yes	No
<b>Polygon</b>	Yes	Yes
<b>Multipolygon</b>	Yes	No
<b>GeometryCollection</b>	Yes	No

Compatible GEOGRAPHY pairs:

<b>Data Type</b>	<b>GEOGRAPHY (WGS84)</b>
Point-Point	No
Linestring-Point	No
Polygon-Point	Yes
Multipolygon-Point	No

Examples

The following examples show how to use ST\_Intersects.

Two polygons do not intersect or touch:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
 ST_GeomFromText('POLYGON((1 0,1 2,2 1 0)'));
ST_Intersects

f
(1 row)
```

Two polygons touch at a single point:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
 ST_GeomFromText('POLYGON((1 0,1 1,0 1,1 0)'));
ST_Intersects

t
(1 row)
```

Two polygons intersect:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2)'),
 ST_GeomFromText('POLYGON((0 2, -1 3, -2 0, 0 2)'));
ST_Intersects

t
(1 row)
```

See also

[ST\\_Disjoint](#)

[ST\\_IsEmpty](#)

Determines if a spatial object represents the empty set. An empty object has no dimension.

Behavior type

[Immutable](#)

Syntax

```
ST_IsEmpty(g)
```

Arguments

***g***  
Spatial object, type GEOMETRY or GEOGRAPHY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following example shows how to use ST\_IsEmpty.

An empty polygon:

```
=> SELECT ST_IsEmpty(ST_GeomFromText('GeometryCollection EMPTY'));
ST_IsEmpty

t
(1 row)
```

### ST\_IsSimple

Determines if a spatial object does not intersect itself or touch its own boundary at any point.

Behavior type

[Immutable](#)

Syntax

```
ST_IsSimple(g)
```

Arguments

***g***

Spatial object, type GEOMETRY or GEOGRAPHY

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	Yes
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Examples

The following examples show how to use ST\_IsSimple.

Polygon does not intersect itself:

```
=> SELECT ST_IsSimple(ST_GeomFromText('POLYGON((-1 2,0 3,1 2,1 -2,-1 2))));
```

```
ST_IsSimple
```

```

```

```
t
```

```
(1 row)
```

Linestring intersects itself.:

```
=> SELECT ST_IsSimple(ST_GeographyFromText('LINESTRING(10 10,25 25,26 34.5,10 30,10 20,20 10)'));
```

```
St_IsSimple
```

```

```

```
f
```

```
(1 row)
```

Linestring touches its interior at one or more locations:

```
=> SELECT ST_IsSimple(ST_GeomFromText('LINESTRING(0 0,0 1,1 0,2 1,2 0,0 0)'));
```

```
ST_IsSimple
```

```

```

```
f
```

```
(1 row)
```

### ST\_IsValid

Determines if a spatial object is well formed or valid. If the object is valid, ST\_IsValid returns TRUE; otherwise, it returns FALSE. Use STV\_IsValidReason to identify the location of the invalidity.

Spatial validity applies only to polygons and multipolygons. A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior do not touch the boundary of the exterior polygon except at a vertex.

The [Open Geospatial Consortium \(OGC\)](#) defines the validity of a polygon in section 6.1.11.1 of the [Simple Feature Access Part 1 - Common Architecture](#) specification.

If you are not sure if a polygon is valid, run ST\_IsValid first. If you pass an invalid spatial object to a Vertica Place function, the function fails or returns incorrect results.

Behavior type

## Immutable

### Syntax

```
ST_IsValid(g)
```

### Arguments

***g***

Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84).

### Returns

BOOLEAN

### Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	Yes
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

### Examples

The following examples show how to use ST\_IsValid.

Valid polygon:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,1 3,3 3,3 1,1 1))));
```

```
ST_IsValid
```

```

```

```
t
```

```
(1 row)
```

Invalid polygon:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 3,3 2,1 1,3 0,1 0,1 3))));
```

```
ST_IsValid
```

```

```

```
f
```

```
(1 row)
```

Invalid polygon:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((0 0,2 2,0 2,2 0,0 0))));
```

```
ST_IsValid
```

```

```

```
f
```

```
(1 row)
```

Invalid multipolygon:

```
=> SELECT ST_IsValid(ST_GeomFromText('MULTIPOLYGON(((0 0, 0 1, 1 1, 0 0)),
((0.5 0.5, 0.7 0.5, 0.7 0.7, 0.5 0.7, 0.5 0.5))));
```

```
ST_IsValid
```

```

```

```
t
```

```
(1 row)
```

Valid polygon with hole:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,3 3,6 -1,0.5 -1,1 1),
(1 1,3 1,2 0,1 1))));
```

```
ST_IsValid
```

```

```

```
t
```

```
(1 row)
```

Invalid polygon with hole:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,3 3,6 -1,0.5 -1,1 1),
(1 1,4.5 1,2 0,1 1))));
```

```
ST_IsValid
```

```

```

```
f
```

```
(1 row)
```

ST\_Length

Calculates the length of a spatial object. For GEOMETRY objects, the length is measured in Cartesian coordinate units. For GEOGRAPHY objects, the length is measured in meters.

Calculates the length as follows:

- The length of a point or multipoint object is 0.
- The length of a linestring is the sum of the lengths of each line segment. The length of a line segment is the distance from the start point to the end point.
- The length of a polygon is the sum of the lengths of the exterior boundary and any interior boundaries.
- The length of a multilinestring, multipolygon, or geometrycollection is the sum of the lengths of all the objects it contains.

#### Note

ST\_Length does not calculate the length of WKTs or WKBs. To calculate the lengths of those objects, use the Vertica [LENGTH](#) SQL function with ST\_AsBinary or ST\_AsText.

Behavior type

[Immutable](#)

Syntax

```
ST_Length(g)
```

Arguments

***g***

Spatial object for which you want to calculate the length, type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes

Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

#### Examples

The following examples show how to use ST\_Length.

Returns length in Cartesian coordinate units:

```
=> SELECT ST_Length(ST_GeomFromText('LINESTRING(-1 -1,2 2,4 5,6 7)'));
 ST_Length

10.6766190873295
(1 row)
```

Returns length in meters:

```
=> SELECT ST_Length(ST_GeographyFromText('LINESTRING(-56.12 38.26,-57.51 39.78,
-56.37 45.24)'));
 ST_Length

821580.025733461
(1 row)
```

#### ST\_NumGeometries

Returns the number of geometries contained within a spatial object. Single GEOMETRY or GEOGRAPHY objects return 1 and empty objects return NULL.

Behavior type

[Immutable](#)

Syntax

```
ST_NumGeometries(g)
```

Arguments

***g***

Spatial object of type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

#### Examples

The following example shows how to use ST\_NumGeometries.

Return the number of geometries:

```
=> SELECT ST_NumGeometries(ST_GeomFromText('MULTILINESTRING ((1 5, 2 4, 5 3, 6 6), (3 5, 3 7))'));
ST_NumGeometries

 2
(1 row)
```

See also

[ST\\_GeometryN](#)

[ST\\_NumPoints](#)

Calculates the number of vertices of a spatial object, empty objects return NULL.

The first and last vertex of polygons and multipolygons are counted separately.

Behavior type

[Immutable](#)

Syntax

```
ST_NumPoints(g)
```

Arguments

***g***

Spatial object for which you want to count the vertices, type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST\_NumPoints.

Returns the number of vertices in a linestring:

```
=> SELECT ST_NumPoints(ST_GeomFromText('LINESTRING(1.33 1.56,2.31 3.4,2.78 5.82,
3.76 3.9,4.11 3.27,5.85 4.34,6.9 4.231,7.61 5.77)'));
ST_NumPoints

 8
(1 row)
```

Use ST\_Boundary and ST\_NumPoints to return the number of vertices of a polygon:

```
=> SELECT ST_NumPoints(ST_Boundary(ST_GeomFromText('POLYGON((1 2,1 4,
 2 5,3 6,4 6,5 5,4 4,3 3,1 2)))));
ST_NumPoints

 9
(1 row)
```

## ST\_Overlaps

Determines if a GEOMETRY object shares space with another GEOMETRY object, but is not completely contained within that object. They must overlap at their interiors. If two objects touch at a single point or intersect only along a boundary, they do not overlap. Both parameters must have the same dimension; otherwise, ST\_Overlaps returns FALSE.

### Behavior type

[Immutable](#)

### Syntax

```
ST_Overlaps (g1, g2)
```

### Arguments

#### ***g1***

Spatial object, type GEOMETRY

#### ***g2***

Spatial object, type GEOMETRY

### Returns

BOOLEAN

### Supported data types

#### **Data Type**

GEOMETRY

#### **Point**

Yes

#### **Multipoint**

Yes

#### **Linestring**

Yes

#### **Multilinestring**

Yes

#### **Polygon**

Yes

#### **Multipolygon**

Yes

#### **GeometryCollection**

Yes

### Examples

The following examples show how to use ST\_Overlaps.

Polygon\_1 overlaps but does not completely contain Polygon\_2:

```
=> SELECT ST_Overlaps(ST_GeomFromText('POLYGON((0 0, 0 1, 1 1, 0 0))'),
 ST_GeomFromText('POLYGON((0.5 0.5, 0.7 0.5, 0.7 0.7, 0.5 0.7, 0.5 0.5))'));
ST_Overlaps

t
(1 row)
```

Two objects with different dimensions:

```
=> SELECT ST_Overlaps(ST_GeomFromText('LINESTRING(2 2,4 4)'),
 ST_GeomFromText('POINT(3 3)'));
ST_Overlaps

f
(1 row)
```

## ST\_PointFromGeoHash

Returns the center point of the specified GeoHash.

Behavior type

[Immutable](#)

Syntax

```
ST_PointFromGeoHash(GeoHash)
```

Arguments

### **GeoHash**

A valid GeoHash string of arbitrary length.

Returns

GEOGRAPHY POINT

Examples

The following examples show how to use ST\_PointFromGeoHash.

Returns the geography point of a high-level GeoHash and uses [ST\\_AsText](#) to convert that point into Well-Known Text:

```
=> SELECT ST_AsText(ST_PointFromGeoHash('dr'));
ST_AsText

POINT (-73.125 42.1875)
(1 row)
```

Returns the geography point of a detailed GeoHash and uses ST\_AsText to convert that point into Well-Known Text:

```
=> SELECT ST_AsText(ST_PointFromGeoHash('1234567890bcdefhjkmn'));
ST_AsText

POINT (-122.196077187 -88.2297377551)
(1 row)
```

## ST\_PointN

Finds the  $n^{\text{th}}$  point of a spatial object. If you pass a negative number, zero, or a number larger than the total number of points on the linestring, ST\_PointN returns NULL.

The vertex order is based on the Well-Known Text (WKT) representation of the spatial object.

Behavior type

[Immutable](#)

Syntax

```
ST_PointN(g, n)
```

Arguments

**g**  
Spatial object to search, type GEOMETRY or GEOGRAPHY

**n**  
Point in the spatial object to be returned. The index is one-based, type INTEGER

Returns

GEOMETRY or GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST\_PointN.

Returns the fifth point:

```
=> SELECT ST_AsText(ST_PointN(ST_GeomFromText('
 POLYGON((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))', 5));
 ST_AsText

POINT (4 6)
(1 row)
```

Returns the second point:

```
=> SELECT ST_AsText(ST_PointN(ST_GeographyFromText('
 LINESTRING(23.41 24.93,34.2 32.98,40.7 41.19)', 2));
 ST_AsText

POINT (34.2 32.98)
(1 row)
```

ST\_Relate

Determines if a given GEOMETRY object is spatially related to another GEOMETRY object, based on the specified DE-9IM pattern matrix string.

The DE-9IM standard identifies how two objects are spatially related to each other.

Behavior type

[Immutable](#)

Syntax

```
ST_Relate(g1, g2, matrix)
```

Arguments

**g1**

Spatial object, type GEOMETRY

**g2**

Spatial object, type GEOMETRY

**matrix**

DE-9IM pattern matrix string, type CHAR(9). This string represents a 3 x 3 matrix of restrictions on the dimensions of the respective intersections of the interior, boundary, and exterior of the two geometries. Must contain exactly 9 of the following characters:

- T
- F
- 0
- 1
- 2
- \*

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST\_Relate.

The DE-9IM pattern for "equals" is 'T\*F\*\*FFF2' :

```
=> SELECT ST_Relate(ST_GeomFromText('LINESTRING(0 1,2 2)'),
 ST_GeomFromText('LINESTRING(2 2,0 1)'), 'T*F**FFF2');
ST_Relate

t
(1 row)
```

The DE-9IM pattern for "overlaps" is 'T\*T\*\*\*T\*\*' :

```
=> SELECT ST_Relate(ST_GeomFromText('POLYGON((-1 -1,0 1,2 2,-1 -1))'),
 ST_GeomFromText('POLYGON((0 1,1 -1,1 1,0 1))'), 'T*T***T**');
ST_Relate

t
(1 row)
```

## ST\_SRID

Identifies the spatial reference system identifier (SRID) stored with a spatial object.

The SRID of a GEOMETRY object can only be determined when passing an SRID to either ST\_GeomFromText or ST\_GeomFromWKB. ST\_SRID returns this stored value. SRID values of 0 to  $2^{32}-1$  are valid.

Behavior type

[Immutable](#)

Syntax

```
ST_SRID(g)
```

Arguments

**g**

Spatial object for which you want the SRID, type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following examples show how to use ST\_SRID.

The default SRID of a GEOMETRY object is 0:

```
=> SELECT ST_SRID(ST_GeomFromText(
 'POLYGON((-1 -1,2 2,0 1,-1 -1))');
ST_SRID

0
(1 row)
```

The default SRID of a GEOGRAPHY object is 4326:

```
=> SELECT ST_SRID(ST_GeographyFromText(
 'POLYGON((22 35,24 35,26 32,22 35))');
ST_SRID

4326
(1 row)
```

## ST\_SymDifference

Calculates all the points in two GEOMETRY objects except for the points they have in common, but including the boundaries of both objects.

This result is called the symmetric difference and is represented mathematically as:  $\text{Closure}(g1 - g2) \dot{\cup} \text{Closure}(g2 - g1)$

Behavior type

[Immutable](#)

Syntax

```
ST_SymDifference(g1, g2)
```

Arguments

***g1***

Spatial object, type GEOMETRY

***g2***

Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST\_SymDifference.

Returns the two linestrings:

```
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('LINESTRING(30 40,
 30 55)'),ST_GeomFromText('LINESTRING(30 32.5,30 47.5)'));
 ST_AsText

MULTILINESTRING ((30 47.5, 30 55),(30 32.5,30 40))
(1 row)
```

Returns four squares:

```
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('POLYGON((2 1,2 4,3 4,
 3 1,2 1)'),ST_GeomFromText('POLYGON((1 2,1 3,4 3,4 2,1 2)'))));
 ST_AsText
```

```

MULTIPOLYGON (((2 1, 2 2, 3 2, 3 1, 2 1)), ((1 2, 1 3, 2 3, 2 2, 1 2)),
((2 3, 2 4, 3 4, 3 3, 2 3)), ((3 2, 3 3, 4 3, 4 2, 3 2))
(1 row)
```

**ST\_Touches**

Determines if two GEOMETRY objects touch at a single point or along a boundary, but do not have interiors that intersect.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior type

[Immutable](#)

Syntax

```
ST_Touches(g1, g2
 [USING PARAMETERS spheroid={true | false}])
```

Arguments

**g1**  
Spatial object, value of type GEOMETRY

**g2**  
Spatial object, value of type GEOMETRY

Parameters

**spheroid = {true | false}**

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

**Default :** False

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No

GeometryCollection	Yes	No
--------------------	-----	----

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (WGS84)
Point-Point	No
Linestring-Point	No
Polygon-Point	Yes
Multipolygon-Point	No

### Examples

The following examples show how to use ST\_Touches.

Two polygons touch at a single point:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
 ST_GeomFromText('POLYGON((1 3,0 3,1 2,1 3))'));
ST_Touches

t
(1 row)
```

Two polygons touch only along part of the boundary:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
 ST_GeomFromText('POLYGON((1 2,0 3,0 1,1 2))'));
ST_Touches

t
(1 row)
```

Two polygons do not touch at any point:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
 ST_GeomFromText('POLYGON((0 2,-1 3,-2 0,0 2))'));
ST_Touches

f
(1 row)
```

### ST\_Transform

Returns a new GEOMETRY with its coordinates converted to the spatial reference system identifier (SRID) used by the `srid` argument.

This function supports the following transformations:

- EPSG 4326 (WGS84) to EPSG 3857 (Web Mercator)
- EPSG 3857 (Web Mercator) to EPSG 4326 (WGS84)

For EPSG 4326 (WGS84), unless the coordinates fall within the following ranges, conversion results in failure:

- Longitude limits: -572 to +572
- Latitude limits: -89.9999999 to +89.9999999

### Behavior type

[Immutable](#)

### Syntax

```
ST_Transform(g1, srid)
```

## Arguments

### ***g1***

Spatial object of type GEOMETRY.

### ***srid***

Spatial reference system identifier (SRID) to which you want to convert your spatial object, of type INTEGER.

## Returns

GEOMETRY

## Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	No
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

## Examples

The following example shows how you can transform data from Web Mercator (3857) to WGS84 (4326):

```
=> SELECT ST_AsText(ST_Transform(STV_GeometryPoint(7910240.56433, 5215074.23966, 3857), 4326));
 ST_AsText

POINT (71.0589 42.3601)
(1 row)
```

The following example shows how you can transform linestring data in a table from WGS84 (4326) to Web Mercator (3857):

```
=> CREATE TABLE transform_line_example (g GEOMETRY);
CREATE TABLE
=> COPY transform_line_example (gx FILLER LONG VARCHAR, g AS ST_GeomFromText(gx, 4326)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> LINESTRING(0 0, 1 1, 2 2, 3 4)
>> \.
=> SELECT ST_AsText(ST_Transform(g, 3857)) FROM transform_line_example;
 ST_AsText

LINESTRING (0 -7.08115455161e-10, 111319.490793 111325.142866, 222638.981587 222684.208506, 333958.47238 445640.109656)
(1 row)
```

The following example shows how you can transform point data in a table from WGS84 (4326) to Web Mercator (3857):

```

=> CREATE TABLE transform_example (x FLOAT, y FLOAT, srid INT);
CREATE TABLE
=> COPY transform_example FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42.3601|71.0589|4326
>> 122.4194|37.7749|4326
>> 94.5786|39.0997|4326
>> \.
=> SELECT ST_AsText(ST_Transform(STV_GeometryPoint(x, y, srid), 3857)) FROM transform_example;
 ST_AsText

POINT (4715504.76195 11422441.5961)
POINT (13627665.2712 4547675.35434)
POINT (10528441.5919 4735962.8206)
(3 rows)

```

## ST\_Union

Calculates the union of all points in two spatial objects.

This result is represented mathematically by:  $g1 \cup g2$

Behavior type

[Immutable](#)

Syntax

```
ST_Union(g1, g2)
```

Arguments

***g1***

Spatial object, type GEOMETRY

***g2***

Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following example shows how to use ST\_Union.

Returns a polygon that represents all the points contained in these two polygons:

```
=> SELECT ST_AsText(ST_Union(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,-1 1,0 2)'),
 ST_GeomFromText('POLYGON((-1 2, 0 0, -2 0, -1 2)'))));
 ST_AsText

POLYGON ((0 2, 1 1, 0 -1, -0.5 0, -2 0, -1 2, -0.666666666667 1.333333333333, 0 2))
(1 row)
```

### ST\_Within

If spatial object **g1** is completely inside of spatial object **g2**, then ST\_Within returns true. Both parameters must be the same spatial data type. Either specify two GEOMETRY objects or two GEOGRAPHY objects.

If an object such as a point or linestring only exists along a polygon's boundary, then ST\_Within returns false. The interior of a linestring is all the points along the linestring except the start and end points.

ST\_Within(**g`g**) is functionally equivalent to ST\_Contains(**g`g**).

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

### Behavior type

[Immutable](#)

### Syntax

```
ST_Within(g1, g2
 [USING PARAMETERS spheroid={true | false}])
```

### Arguments

#### **g1**

Spatial object, type GEOMETRY or GEOGRAPHY

#### **g2**

Spatial object, type GEOMETRY or GEOGRAPHY

### Parameters

#### **spheroid = {true | false}**

(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84.

**Default** : False

### Returns

BOOLEAN

### Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	No	No
Linestring	Yes	Yes	No
Multilinestring	Yes	No	No

Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	No
Point-Linestring	Yes	No
Point-Polygon	Yes	Yes
Point-Multipolygon	Yes	No

### Examples

The following examples show how to use ST\_Within.

The first polygon is completely contained within the second polygon:

```
=> SELECT ST_Within(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
 ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))');
ST_Within

t
(1 row)
```

The point is on a vertex of the polygon, but not in its interior:

```
=> SELECT ST_Within (ST_GeographyFromText('POINT(30 25)'),
 ST_GeographyFromText('POLYGON((25 25,25 35,32.2 35,30 25,25 25))'));
ST_Within

f
(1 row)
```

Two polygons are spatially equivalent:

```
=> SELECT ST_Within (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
 ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3))');
ST_Within

t
(1 row)
```

See also

- [ST\\_Contains](#)
- [ST\\_Overlaps](#)

### ST\_X

Determines the *x* - coordinate for a GEOMETRY point or the longitude value for a GEOGRAPHY point.

Behavior type

[Immutable](#)

Syntax

```
ST_X(g)
```

Arguments

**g**

Point of type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use ST\_X.

Returns the *x*-coordinate:

```
=> SELECT ST_X(ST_GeomFromText('POINT(3.4 1.25)'));
ST_X

3.4
(1 row)
```

Returns the longitude value:

```
=> SELECT ST_X(ST_GeographyFromText('POINT(25.34 45.67)'));
ST_X

25.34
(1 row)
```

ST\_XMax

Returns the maximum *x*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum longitude of the great circle arc from (MAX(longitude), ST\_YMin(GEOGRAPHY)) to (MAX(longitude), ST\_YMax(GEOGRAPHY)). In this case, MAX(longitude) is the maximum longitude value of the geography object.

If either latitude or longitude is out of range, ST\_XMax returns the maximum plain value of the geography object.

Behavior type

[Immutable](#)

Syntax

ST\_XMax( *g* )

Arguments

**g**Spatial object for which you want to find the maximum *x*-coordinate, type GEOMETRY or GEOGRAPHY.

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST\_XMax.

Returns the maximum *x*-coordinate within a rectangle:

```
=> SELECT ST_XMax(ST_GeomFromText('POLYGON((0 1,0 2,1 2,1 1,0 1))');
 ST_XMax

 1
(1 row)
```

Returns the maximum longitude value within a rectangle:

```
=> SELECT ST_XMax(ST_GeographyFromText(
 'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
 ST_XMax

 -71
(1 row)
```

ST\_XMin

Returns the minimum *x*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum longitude of the great circle arc from (MIN(longitude), ST\_YMin(GEOGRAPHY)) to (MIN(longitude), ST\_YMax(GEOGRAPHY)). In this case, MIN(longitude) represents the minimum longitude value of the geography object

If either latitude or longitude is out of range, ST\_XMin returns the minimum plain value of the geography object.

Behavior type

[Immutable](#)

Syntax

```
ST_XMin(g)
```

Arguments

***g***

Spatial object for which you want to find the minimum *x*-coordinate, type GEOMETRY or GEOGRAPHY.

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

## Examples

The following examples show how to use ST\_XMin.

Returns the minimum *x*-coordinate within a rectangle:

```
=> SELECT ST_XMin(ST_GeomFromText('POLYGON((0 1,0 2,1 2,1 1,0 1))');
 ST_XMin

 0
(1 row)
```

Returns the minimum longitude value within a rectangle:

```
=> SELECT ST_XMin(ST_GeographyFromText(
 'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
 ST_XMin

 -71.5
(1 row)
```

## ST\_Y

Determines the *y*-coordinate for a GEOMETRY point or the latitude value for a GEOGRAPHY point.

Behavior type

[Immutable](#)

Syntax

```
ST_Y(g)
```

Arguments

***g***  
Point of type GEOMETRY or GEOGRAPHY

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	No	No	No
Linestring	No	No	No

Multilinestring	No	No	No
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

## Examples

The following examples show how to use ST\_Y.

Returns the *y*-coordinate:

```
=> SELECT ST_Y(ST_GeomFromText('POINT(3 5.25)'));
ST_Y

5.25
(1 row)
```

Returns the latitude value:

```
=> SELECT ST_Y(ST_GeographyFromText('POINT(35.44 51.04)'));
ST_Y

51.04
(1 row)
```

## ST\_YMax

Returns the maximum *y*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum latitude of the great circle arc from (ST\_XMin(GEOGRAPHY), MAX(latitude)) to (ST\_XMax(GEOGRAPHY), MAX(latitude)). In this case, MAX(latitude) is the maximum latitude value of the geography object.

If either latitude or longitude is out of range, ST\_YMax returns the maximum plain value of the geography object.

Behavior type

[Immutable](#)

Syntax

```
ST_YMax(g)
```

Arguments

**g**

Spatial object for which you want to find the maximum *y*-coordinate, type GEOMETRY or GEOGRAPHY.

Returns

FLOAT

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes

Multipolygon	Yes	Yes
GeometryCollection	Yes	No

## Examples

The following examples show how to use ST\_YMax.

Returns the maximum *y*-coordinate within a rectangle:

```
=> SELECT ST_YMax(ST_GeomFromText('POLYGON((0 1,0 4,1 4,1 1,0 1))'));
ST_YMax

4
(1 row)
```

Returns the maximum latitude value within a rectangle:

```
=> SELECT ST_YMax(ST_GeographyFromText(
'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
ST_YMax

42.3802715689979
(1 row)
```

## ST\_YMin

Returns the minimum *y*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum latitude of the great circle arc from (ST\_XMin(GEOGRAPHY), MIN(latitude)) to (ST\_XMax(GEOGRAPHY), MIN(latitude)). In this case, MIN(latitude) represents the minimum latitude value of the geography object.

If either latitude or longitude is out of range, ST\_YMin returns the minimum plain value of the geography object.

## Behavior type

[Immutable](#)

## Syntax

```
ST_YMin(g)
```

## Arguments

### *g*

Spatial object for which you want to find the minimum *y*-coordinate, type GEOMETRY or GEOGRAPHY.

## Returns

FLOAT

## Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes

<b>GeometryCollection</b>	Yes	No
---------------------------	-----	----

## Examples

The following examples show how to use ST\_YMin.

Returns the minimum *y*-coordinate within a rectangle:

```
=> SELECT ST_YMin(ST_GeomFromText('POLYGON((0 1,0 4,1 4,1 1,0 1))'));
ST_YMin

1
(1 row)
```

Returns the minimum latitude value within a rectangle:

```
=> SELECT ST_YMin(ST_GeographyFromText(
'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
ST_YMin

42.35
(1 row)
```

## STV\_AsGeoJSON

Returns the geometry or geography argument as a Geometry Javascript Object Notation (GeoJSON) object.

Behavior type

[Immutable](#)

Syntax

```
STV_AsGeoJSON(g, [USING PARAMETERS maxdecimals=dec_value])
```

Arguments

***g***

Spatial object of type GEOMETRY or GEOGRAPHY

**maxdecimals = *dec\_value***

(Optional) Integer value. Determines the maximum number of digits to output after the decimal of floating point coordinates.

**Valid values** **\*\*:\*\*** Between 0 and 15.

**Default** **\*\* value\*\*\*\*:\*\*** 6

Returns

LONG VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

## Examples

The following examples show how you can use STV\_AsGeoJSON.

Convert a geometry polygon to GeoJSON:

```
=> SELECT STV_AsGeoJSON(ST_GeomFromText('POLYGON((3 2, 4 3, 5 1, 3 2), (3.5 2, 4 2.5, 4.5 1.5, 3.5 2))));
 STV_AsGeoJSON

{"type":"Polygon","coordinates":[[[3,2],[4,3],[5,1],[3,2]],[[3.5,2],[4,2.5],[4.5,1.5],[3.5,2]]]}
(1 row)
```

Convert a geography point to GeoJSON:

```
=> SELECT STV_AsGeoJSON(ST_GeographyFromText('POINT(42.36011 71.05899)') USING PARAMETERS maxdecimals=4);
 STV_AsGeoJSON

{"type":"Point","coordinates":[42.3601,71.059]}
(1 row)
```

## STV\_Create\_Index

Creates a spatial index on a set of polygons to speed up spatial intersection with a set of points.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

### Important

You cannot access spatial indexes on newly added nodes without rebalancing your cluster. For more information, see [REBALANCE\\_CLUSTER](#).

### Behavior type

[Immutable](#)

#### Note

Indexes are not connected to any specific table. Subsequent DML commands on the underlying table or tables of the input data source do not modify the index.

## Syntax

```
STV_Create_Index(gid, g
 USING PARAMETERS index='index_name'
 [, overwrite={ true | false }]
 [, max_mem_mb=maxmem_value]
 [, skip_nonindexable_polygons={true | false }])
OVER()
[AS (polygons, srid, min_x, min_y, max_x, max_y, info)]
```

### Arguments

#### *gid*

Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.

#### *g*

Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.

### Parameters

#### **index = 'index\_name'**

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

#### **overwrite = [ true | false ]**

Boolean, whether to overwrite the index, if an index exists. This parameter cannot be NULL.

**Default:** False

**max\_mem\_mb = maxmem\_value**

A positive integer that assigns a limit to the amount of memory in megabytes that `STV_Create_Index` can allocate during index construction. On a multi-node database this is the memory limit per node. The default value is 256. Do not assign a value higher than the amount of memory in the GENERAL resource pool. For more information about this pool, see [Monitoring resource pools](#).

Setting a value for `max_mem_mb` that is at or near the maximum memory available on the node can negatively affect your system's performance. For example, it could cause other queries to time out waiting for memory resources during index construction.

**skip\_nonindexable\_polygons = [ true | false ]**

(Optional) BOOLEAN

In rare cases, intricate polygons (for instance, with too high resolution or anomalous spikes) cannot be indexed. These polygons are considered non-indexable. When set to False, non-indexable polygons cause the index creation to fail. When set to True, index creation can succeed by excluding non-indexable polygons from the index.

To review the polygons that were not able to be indexed, use `STV_Describe_Index` with the parameter `list_polygon`.

Default: False

Returns

**polygons**

Number of polygons indexed.

**SRID**

Spatial reference system identifier.

**min\_x, min\_y, max\_x, max\_y**

Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. ( `min_x` , `min_y` ) are the south-west coordinates, and ( `max_x` , `max_y` ) are the north-east coordinates.

**info**

Lists the number of excluded spatial objects as well as their type that were excluded from the index.

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	No	No
Multipoint	No	No
Linestring	No	No
Multilinestring	No	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Privileges

Any user with access to the `STV_*_Index` functions can describe, rename, or drop indexes created by any other user.

Recommendations

- Segment large polygon tables across multiple nodes. Table segmentation causes index creation to run in parallel, leveraging the Massively Parallel Processing (MPP) architecture in Vertica. This significantly reduces execution time on large tables. Vertica recommends that you segment the table from which you are building the index when the total number of polygons is large.
- `STV_Create_Index` can consume large amounts of processing time and memory. Vertica recommends that when indexing new data for the first time, you monitor memory usage to be sure it stays within safe limits. Memory usage depends on number of polygons, number of vertices, and the amount of overlap among polygons.

- STV\_Create\_Index tries to allocate memory before it starts creating the index. If it cannot allocate enough memory, the function fails. If not enough memory is available, try the following:
  - Create the index at a time of less load on the system.
  - Avoid concurrent index creation.
  - Try segmenting the input table across the nodes of the cluster.
- Ensure that all of the polygons you plan to index are valid polygons. STV\_Create\_Index and STV\_Refresh\_Index do not check polygon validity when building an index.

For more information, see [Ensuring polygon validity before creating or refreshing an index](#).

#### Limitations

- Any indexes created prior to 24.3.x need to re-created.
- Index creation fails if there are WGS84 polygons with vertices on the International Date Line (IDL) or the North and South Poles.
- The backslash or tab characters are not allowed in index names.
- Indexes cannot have names greater than 110 characters.
- The following geometries are excluded from the index:
  - Non-polygons
  - Geometries with NULL identifiers
  - NULL (multi) polygon
  - EMPTY (multi) polygon
  - Invalid (multi) polygon
- The following geographies are excluded from the index:
  - Polygons with holes
  - Polygons crossing the International Date Line
  - Polygons covering the north or south pole
  - Antipodal polygons

#### Usage tips

- To cancel an STV\_Create\_Index run, use **Ctrl + C**.
- If there are no valid polygons in the geom column, STV\_Create\_Index reports an error in vertica.log and stops index creation.
- If index creation uses a large amount of memory, consider segmenting your data to utilize parallel index creation.

#### Examples

The following examples show how to use STV\_Create\_Index.

Create an index with a single literal argument:

```
=> SELECT STV_Create_Index(1, ST_GeomFromText('POLYGON((0 0,0 15.2,3.9 15.2,3.9 0,0 0))')
 USING PARAMETERS index='my_polygon') OVER();
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
 1 | 0 | 0 | 0 | 3.9 | 15.2 |
(1 row)
```

Create an index from a table:

```

=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((10 20,15 60,20 45,46 15,10 20))
>> 4|POLYGON((5 20,9 30,20 45,36 35,5 20))
>> 5|POLYGON((12 23,9 30,20 45,36 35,37 67,45 80,50 20,12 23))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
 max_mem_mb=256) OVER() FROM pols;
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
 5 | 0 | -38 | 13 | 50 | 80 |
(1 row)

```

Create an index in parallel from a partitioned table:

```

=> CREATE TABLE pols (p INT, gid INT, geom GEOMETRY(1000)) SEGMENTED BY HASH(p) ALL NODES;
CREATE TABLE
=> COPY pols (p, gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|10|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 1|11|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|12|POLYGON((-12 42,-12 42,27 48,14 26,-12 42))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true,
 max_mem_mb=256) OVER() FROM pols;
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
 3 | 0 | -38 | 13 | 27 | 74 |
(1 row)

```

See also

- [STV\\_Rename\\_Index](#)
- [Ensuring polygon validity before creating or refreshing an index](#)

STV\_Describe\_Index

Retrieves information about an index that contains a set of polygons. If you do not pass any parameters, STV\_Describe\_Index returns all of the defined indexes.

The OVER() clause must be empty.

Behavior type

[Immutable](#)

Syntax

```

STV_Describe_Index ([USING PARAMETERS [index='index_name']
 [, list_polygons={true | false }]]) OVER ()

```

Arguments

**index = 'index\_name'**

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

## list\_polygon

(Optional) BOOLEAN that specifies whether to list the polygons in the index. The index argument must be used with this argument.

Returns

### **polygons**

Number of polygons indexed.

### **SRID**

Spatial reference system identifier.

### **min\_x , min\_y , max\_x , max\_y**

Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. ( min\_x , min\_y ) are the south-west coordinates, and ( max\_x , max\_y ) are the north-east coordinates.

### **name**

The name of the spatial index(es).

### **gid**

Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.

### **state**

The spatial object's state in the index. Possible values are:

- INDEXED - The spatial object was successfully indexed.
- SELF\_INTERSECT - (WGS84 Only) The spatial object was not indexed because one of its edges intersects with another of its edges.
- EDGE\_CROSS\_IDL - (WGS84 Only) The spatial object was not indexed because one of its edges crosses the International Date Line.
- EDGE\_HALF\_CIRCLE - (WGS84 Only) The spatial object was not indexed because it contains two adjacent vertices that are antipodal.
- NON\_INDEXABLE - The spatial object was not able to be indexed.

### **geography**

The Well-Known Binary (WKB) representation of the spatial object.

### **geometry**

The Well-Known Binary (WKB) representation of the spatial object.

Privileges

Any user with access to the STV\_\*\_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

Some functionality will require the index to be rebuilt if the index was created with 24.3.x or earlier.

Examples

The following examples show how to use STV\_Describe\_Index.

Retrieve information about the index:

```
=> SELECT STV_Describe_Index (USING PARAMETERS index='my_polygons') OVER ();
```

type	polygons	SRID	min_x	min_y	max_x	max_y
GEOMETRY	4	0	-1	-1	12	12

(1 row)

Return the names of all the defined indexes:

```
=> SELECT STV_Describe_Index() OVER ();
```

name
MA_counties_index
my_polygons
NY_counties_index
US_States_Index

(4 rows)

Return the polygons included in an index:

```
=> SELECT STV_Describe_Index(USING PARAMETERS index='my_polygons', list_polygons=TRUE) OVER ();
gid | state | geometry
-----+-----+-----
 12 | INDEXED | \260\000\000\000\000\000\000\ ...
 14 | INDEXED | \200\000\000\000\000\000\000\ ...
 10 | NON_INDEXABLE | \274\000\000\000\000\000\000\ ...
 11 | INDEXED | \260\000\000\000\000\000\000\ ...
(4 rows)
```

See also

- [Spatial joins with ST\\_Intersects and STV\\_Intersect](#)
- [STV\\_Intersect scalar function](#)
- [STV\\_Intersect transform function](#)
- [STV\\_Drop\\_Index](#)
- [STV\\_Rename\\_Index](#)

STV\_Drop\_Index

Deletes a spatial index. If STV\_Drop\_Index cannot find the specified spatial index, it returns an error.

The OVER clause must be empty.

Behavior type

[Immutable](#)

Syntax

```
STV_Drop_Index(USING PARAMETERS index = 'index_name') OVER ()
```

Arguments

**index = '*index\_name*'**

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

Examples

The following example shows how to use STV\_Drop\_Index.

Drop an index:

```
=> SELECT STV_Drop_Index(USING PARAMETERS index ='my_polygons') OVER ();
drop_index

Index dropped
(1 row)
```

See also

- [Spatial joins with ST\\_Intersects and STV\\_Intersect](#)
- [STV\\_Create\\_Index](#)
- [STV\\_Describe\\_Index](#)
- [STV\\_Rename\\_Index](#)
- [STV\\_Intersect scalar function](#)
- [STV\\_Intersect transform function](#)

STV\_DWithin

Determines if the shortest distance from the boundary of one spatial object to the boundary of another object is within a specified distance.

Parameters *g1* and *g2* must be both GEOMETRY objects or both GEOGRAPHY objects.

Behavior type

[Immutable](#)

Syntax

```
STV_DWithin(g1, g2, d)
```

Arguments

**g1**

Spatial object of type GEOMETRY or GEOGRAPHY

**g2**

Spatial object of type GEOMETRY or GEOGRAPHY

**d**

Value of type FLOAT indicating a distance. For GEOMETRY objects, the distance is measured in Cartesian coordinate units. For GEOGRAPHY objects, the distance is measured in meters.

Returns

BOOLEAN

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

**Data Type**

GEOGRAPHY (Perfect Sphere)

**Point-Point**

Yes

**Point-Linestring**

Yes

**Point-Polygon**

Yes

**Point-Multilinestring**

Yes

**Point-Multipolygon**

Yes

Examples

The following examples show how to use STV\_DWithin.

Two geometries are one Cartesian coordinate unit from each other at their closest points:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
 ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3)'),1);
STV_DWithin

t
(1 row)
```

If you reduce the distance to 0.99 units:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
 ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3)'),0.99);
STV_DWithin

f
(1 row)
```

The first polygon touches the second polygon:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
 ST_GeomFromText('POLYGON((1 1,2 3,4 5,1 1)'),0.00001);
STV_DWithin

t
(1 row)
```

The first polygon is not within 1000 meters from the second polygon:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((45.2 40,50.65 51.29,
 55.67 47.6,50 47.6,45.2 40)'),ST_GeomFromText('POLYGON((25 25,25 30,
 30 30,30 25,25 25)'), 1000);
STV_DWithin

t
(1 row)
```

## STV\_Export2Shapefile

Exports GEOGRAPHY or GEOMETRY data from a database table or a subquery to a shapefile. Output is written to the directory set with [STV\\_SetExportShapefileDirectory](#).

Behavior type

[Immutable](#)

Syntax

```
STV_Export2Shapefile(columns USING PARAMETERS shapefile = 'filename'
 [, overwrite = boolean]
 [, shape = 'spatial-class'])
OVER()
```

Arguments

### **columns**

The columns to export to the shapefile.

A value of asterisk (\*) is the equivalent to listing all columns of the FROM clause.

Parameters

### **shapefile**

Prefix of the component names of the shapefile. The following requirements apply:

- Must end with the file extension **.shp** .
- Limited to 128 octets in length—for example, **city-data.shp** .

To save the shapefile to a subdirectory, concatenate the subdirectory to **shapefile-name** —for example, **visualizations/city-data.shp** . The subdirectory must exist; this function does not create it.

### **overwrite**

Boolean, whether to overwrite the index, if an index exists. This parameter cannot be NULL.

**Default:** False

### **shape**

One of the following spatial classes:

- Point
- Polygon
- Linestring

- Multipoint
- Multipolygon
- Multilinestring

Polygons and multipolygons always have a clockwise orientation.

**Default:** Polygon

Returns

Three files in the shapefile export directory with the extensions `.shp` , `.shx` , and `.dbf` .

Limitations

- If a multipolygon, multilinestring, or multipoint contains only one element, then it is written as a polygon, line, or point, respectively.
- Column names longer than 10 characters are truncated.
- Empty POINTS cannot be exported.
- All rows with NULL geometry or geography data are skipped.
- Unsupported or invalid dates are replaced with NULLs.
- Numeric values may lose precision when they are exported. This loss occurs because the target field in the `.dbf` file is a 64-bit FLOAT column, which can only represent about 15 significant digits.
- Shapefiles cannot exceed 4GB in size. If your shapefile is too large, try splitting the data and exporting to multiple shapefiles.

Examples

The following example shows how you can use `STV_Export2Shapefile` to export all columns from the table `geo_data` to a shapefile named `city-data.shp`:

```
=> SELECT STV_Export2Shapefile(*
 USING PARAMETERS shapefile = 'visualizations/city-data.shp',
 overwrite = true, shape = 'Point')
 OVER()
 FROM geo_data
 WHERE REVENUE > 25000;
Rows Exported | File Path
-----+-----
6442892 | v_geo-db_node0001: /home/geo/temp/visualizations/city-data.shp
(1 row)
```

`STV_Extent`

Returns a bounding box containing all of the input data.

Use `STV_Extent` inside of a nested query for best results. The `OVER` clause must be empty.

Important

`STV_Extent` does not return a valid polygon when the input is a single point.

Behavior type

[Immutable](#)

Syntax

```
STV_Extent(g)
```

Arguments

***g***

Spatial object, type GEOMETRY.

Returns

GEOMETRY

Supported data types

Data Type	GEOMETRY
Point	Yes

Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

## Examples

The following examples show how you can use STV\_Extent.

Return the bounding box of a linestring, and verify that it is a valid polygon:

```
=> SELECT ST_AsText(geom) AS bounding_box, ST_IsValid(geom)
FROM (SELECT STV_Extent(ST_GeomFromText('LineString(0 0, 1 1)')) OVER() AS geom) AS g;
 bounding_box | ST_IsValid
-----+-----
POLYGON ((0 0, 1 0, 1 1, 0 1, 0 0)) | t
(1 row)
```

Return the bounding box of spatial objects in a table:

```
=> CREATE TABLE misc_geo_shapes (id IDENTITY, geom GEOMETRY);
CREATE TABLE
=> COPY misc_geo_shapes (gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> POINT(-71.03 42.37)
>> LINESTRING(-71.058849 42.367501, -71.062240 42.371276, -71.067938 42.371246)
>> POLYGON((-71.066030 42.380617, -71.055827 42.376734, -71.060811 42.376011, -71.066030 42.380617))
>> \.
=> SELECT ST_AsText(geom_col) AS bounding_box
FROM (SELECT STV_Extent(geom) OVER() AS geom_col FROM misc_geo_shapes) AS g;
 bounding_box

POLYGON ((-71.067938 42.367501, -71.03 42.367501, -71.03 42.380617, -71.067938 42.380617, -71.067938 42.367501))
(1 row)
```

## STV\_ForceLHR

Alters the order of the vertices of a spatial object to follow the left-hand-rule.

Behavior type

[Immutable](#)

Syntax

```
STV_ForceLHR(g, [USING PARAMETERS skip_nonreorientable_polygons={true | false}])
```

Arguments

***g***

Spatial object, type GEOGRAPHY.

**skip\_nonreorientable\_polygons = { true | false }**

(Optional) Boolean

When set to False, non-orientable polygons generate an error. For example, if you use STV\_ForceLHR or STV\_Reverse with [skip\\_nonorientable\\_polygons](#) set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.

This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.

Vertica Place considers these polygons non-orientable:

- Polygons with a hole
- Multipolygons
- Multipolygons with a hole

**Default value** : False

Returns

GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	Yes	Yes
Multipolygon	No	Yes	Yes
GeometryCollection	No	No	No

Examples

The following example shows how you can use STV\_ForceLHR.

Re-orient a geography polygon to left-hand orientation:

```
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1)'))));
 ST_AsText

POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

Reverse the orientation of a geography polygon by forcing left-hand orientation:

```
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1)'))));
 ST_AsText

POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

See also

[STV\\_Reverse](#)

STV\_Geography

Casts a GEOMETRY object into a GEOGRAPHY object. The SRID value does not affect the results of Vertica Place queries.

When STV\_Geography converts a GEOMETRY object to a GEOGRAPHY object, it sets its SRID to 4326.

Behavior type

[Immutable](#)

Syntax

```
STV_Geography(geom)
```

Arguments

***geom***

Spatial object that you want to cast into a GEOGRAPHY object, type GEOMETRY

Returns

GEOGRAPHY

Supported data types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Examples

The following example shows how to use STV\_Geography.

To calculate the centroid of the GEOGRAPHY object, convert it to a GEOMETRY object, then convert it back to a GEOGRAPHY object:

```
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> MULTIPOINT(-108.619726 45.000284,-107.866813 45.00107,-106.363711 44.994223,-70.847746 41.205814)
>> \.
=> SELECT ST_AsText(STV_Geography(ST_Centroid(STV_Geometry(g)))) FROM geogs;
 ST_AsText

POINT (-98.424499 44.05034775)
(1 row)
```

STV\_GeographyPoint

Returns a GEOGRAPHY point based on the input values.

This is the optimal way to convert raw coordinates to GEOGRAPHY points.

Behavior type

[Immutable](#)

Syntax

```
STV_GeographyPoint(x, y)
```

Arguments

**x**  
x-coordinate or longitude, FLOAT.

**y**  
y-coordinate or latitude, FLOAT.

Returns

GEOGRAPHY

Examples

The following examples show how to use STV\_GeographyPoint.

Return a GEOGRAPHY point:

```
=> SELECT ST_AsText(STV_GeographyPoint(-114.101588, 47.909677));
 ST_AsText

POINT (-114.101588 47.909677)
(1 row)
```

Return GEOGRAPHY points using two columns:

```
=> CREATE TABLE geog_data (id IDENTITY, x FLOAT, y FLOAT);
CREATE TABLE
=> COPY geog_data FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> -114.101588|47.909677
>> -111.532377|46.430753
>> \.
=> SELECT id, ST_AsText(STV_GeographyPoint(x, y)) FROM geog_data;
id | ST_AsText
-----+-----
 1 | POINT (-114.101588 47.909677)
 2 | POINT (-111.532377 46.430753)
(2 rows)
```

Create GEOGRAPHY points by manipulating data source columns during load:

```
=> CREATE TABLE geog_data_load (id IDENTITY, geog GEOGRAPHY);
CREATE TABLE
=> COPY geog_data_load (lon FILLER FLOAT,
 lat FILLER FLOAT,
 geog AS STV_GeographyPoint(lon, lat))
FROM 'test_coords.csv' DELIMITER ',';
Rows Loaded

 2
(1 row)
=> SELECT id, ST_AsText(geog) FROM geog_data_load;
id | ST_AsText
-----+-----
 1 | POINT (-75.101654451 43.363830536)
 2 | POINT (-75.106444487 43.367093798)
(2 rows)
```

See also

[STV\\_GeometryPoint](#)

STV\_Geometry

Casts a GEOGRAPHY object into a GEOMETRY object.

The SRID value does not affect the results of Vertica Place queries.

Behavior type

[Immutable](#)

Syntax

```
STV_Geometry(geog)
```

Arguments

***geog***

Spatial object that you want to cast into a GEOMETRY object, type GEOGRAPHY

Returns

## GEOMETRY

### Supported data types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

### Examples

The following example shows how to use STV\_Geometry.

Convert the GEOGRAPHY values to GEOMETRY values, then convert the result back to a GEOGRAPHY type:

```
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> MULTIPOINT(-108.619726 45.000284,-107.866813 45.00107,-106.363711 44.994223,-70.847746 41.205814)
>> \.
=> SELECT ST_AsText(STV_Geography(ST_Centroid(STV_Geometry(g)))) FROM geogs;
 ST_AsText

POINT (-98.424499 44.05034775)
```

### STV\_GeometryPoint

Returns a GEOMETRY point, based on the input values.

This approach is the most-optimal way to convert raw coordinates to GEOMETRY points.

### Behavior type

[Immutable](#)

### Syntax

```
STV_GeometryPoint(x, y [, srid])
```

### Arguments

**x**

x-coordinate or longitude, FLOAT.

**y**

y-coordinate or latitude, FLOAT.

**srid**

(Optional) Spatial Reference Identifier (SRID) assigned to the point, INTEGER.

### Returns

GEOMETRY

### Examples

The following examples show how to use STV\_GeometryPoint.

Return a GEOMETRY point with an SRID:

```
=> SELECT ST_AsText(STV_GeometryPoint(71.148562, 42.989374, 4326));
 ST_AsText

POINT (-71.148562 42.989374)
(1 row)
```

Return GEOMETRY points using two columns:

```
=> CREATE TABLE geom_data (id IDENTITY, x FLOAT, y FLOAT, SRID int);
CREATE TABLE
=> COPY geom_data FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42.36383053600048|-71.10165445099966|4326
>> 42.3670937980005|-71.10644448699964|4326
>> \.
=> SELECT id, ST_AsText(STV_GeometryPoint(x, y, SRID)) FROM geom_data;
id | ST_AsText
-----+-----
 1 | POINT (-71.101654451 42.363830536)
 2 | POINT (-71.106444487 42.367093798)
(2 rows)
```

Create GEOMETRY points by manipulating data source columns during load:

```
=> CREATE TABLE geom_data_load (id IDENTITY, geom GEOMETRY);
CREATE TABLE
=> COPY geom_data_load (lon FILLER FLOAT,
 lat FILLER FLOAT,
 geom AS STV_GeometryPoint(lon, lat))
FROM 'test_coords.csv' DELIMITER ',';
Rows Loaded

 2
(1 row)
=> SELECT id, ST_AsText(geom) FROM geom_data_load;
id | ST_AsText
-----+-----
 1 | POINT (-75.101654451 43.363830536)
 2 | POINT (-75.106444487 43.367093798)
(2 rows)
```

See also

[STV\\_GeographyPoint](#)

[STV\\_GetExportShapefileDirectory](#)

Returns the path of the export directory.

Behavior type

[Immutable](#)

Syntax

```
STV_GetExportShapefileDirectory()
```

Returns

The path of the shapefile export directory.

Examples

The following example shows how you can use `STV_GetExportShapefileDirectory` to query the path of the shapefile export directory:

```
=> SELECT STV_GetExportShapefileDirectory();
 STV_GetExportShapefileDirectory
```

```
Shapefile export directory: [/home/user/temp]
```

```
(1 row)
```

## STV\_Intersect scalar function

Spatially intersects a point or points with a set of polygons. The STV\_Intersect scalar function returns the identifier associated with an intersecting polygon.

### Behavior type

[Immutable](#)

### Syntax

```
STV_Intersect({ g | x, y }
 USING PARAMETERS index= 'index_name')
```

### Arguments

#### **g**

A geometry or geography (WGS84) column that contains points. The g column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV\_Intersect terminates with an error.

#### **x**

x-coordinate or longitude, FLOAT.

#### **y**

y-coordinate or latitude, FLOAT.

### Parameters

#### **index = ' index\_name '**

Name of the spatial index, of type VARCHAR.

### Returns

The identifier of a matching polygon. If the point does not intersect any of the index's polygons, then the STV\_Intersect scalar function returns NULL.

### Examples

The following examples show how you can use STV\_Intersect scalar.

Using two floats, return the gid of a matching polygon or NULL:

```
=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((31 74,8 70,8 50,36 53,31 74))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
 max_mem_mb=256) OVER() FROM pols;
 type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+
GEOMETRY | 1 | 0 | 8 | 50 | 36 | 74 |
(1 row)

=> SELECT STV_Intersect(12.5683, 55.6761 USING PARAMETERS index = 'my_polygons_1');
STV_Intersect

1
(1 row)
```

Using a GEOMETRY column, return the gid of a matching polygon or NULL:

```

=> CREATE TABLE polygons (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((-18 42,-10 65,27 48,14 26,-18 42))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true,
 max_mem_mb=256) OVER() FROM polygons;
 type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 3 | 0 | -38 | 13 | 27 | 74 |
(1 row)

=> CREATE TABLE points (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 100|POINT(-1 52)
>> 101|POINT(-20 0)
>> 102|POINT(-8 25)
>> 103|POINT(0 0)
>> 104|POINT(1 5)
>> 105|POINT(20 45)
>> 106|POINT(-20 5)
>> 107|POINT(-20 1)
>> \.
=> SELECT gid AS pt_gid, STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
 FROM points ORDER BY pt_gid;
 pt_gid | pol_gid
-----+-----
 100 | 1
 101 |
 102 | 2
 103 |
 104 |
 105 | 3
 106 |
 107 |
(8 rows)

```

- [STV\\_Intersect transform function](#)
- [STV\\_Create\\_Index](#)

STV\_Intersect transform function

Spatially intersects points and polygons. The STV\_Intersect transform function returns a tuple with matching point/polygon pairs. For every point, Vertica returns either one or many matching polygons.

You can improve performance when you parallelize the computation of the STV\_Intersect transform function over multiple nodes. To parallelize the computation, use an OVER(PARTITION BEST) clause.

Behavior type

[Immutable](#)

Syntax

```
STV_Intersect ({ gid | i }, { g | x , y }
 USING PARAMETERS index='index_name')
OVER() AS (pt_gid, pol_gid)
```

#### Arguments

**gid | i**  
An integer column or integer that uniquely identifies the spatial object(s) of *g* or *x* and *y*.

**g**  
A geometry or geography (WGS84) column that contains points. The *g* column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV\_Intersect terminates with an error.

**x**  
x-coordinate or longitude, FLOAT.

**y**  
y-coordinate or latitude, FLOAT.

#### Parameters

**index = 'index\_name'**  
Name of the spatial index, of type VARCHAR.

#### Returns

**pt\_gid**  
Unique identifier of the point geometry or geography, of type INTEGER.

**pol\_gid**  
Unique identifier of the polygon geometry or geography, of type INTEGER.

#### Examples

The following examples show how you can use STV\_Intersect transform.

Using two floats, return the matching point-polygon pairs.

```
=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((31 74,8 70,8 50,36 53,31 74))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
 max_mem_mb=256) OVER() FROM pols;
 type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 1 | 0 | 8 | 50 | 36 | 74 |
(1 row)

=> SELECT STV_Intersect(56, 12.5683, 55.6761 USING PARAMETERS index = 'my_polygons_1') OVER();
pt_gid | pol_gid
-----+-----
56 | 1
(1 row)
```

Using a GEOMETRY column, return the matching point-polygon pairs.

```

=> CREATE TABLE polygons (gid int, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 10|POLYGON((5 5, 5 10, 10 10, 10 5, 5 5))
>> 11|POLYGON((0 0, 0 2, 2 2, 2 0, 0 0))
>> 12|POLYGON((1 1, 1 3, 3 3, 3 1, 1 1))
>> 14|POLYGON((-1 -1, -1 12, 12 12, 12 -1, -1 -1))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true, max_mem_mb=256)
 OVER() FROM polygons;
 type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 4 | 0 | -1 | -1 | 12 | 12 |
(1 row)

```

```

=> CREATE TABLE points (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(9 9)
>> 2|POINT(0 1)
>> 3|POINT(2.5 2.5)
>> 4|POINT(0 0)
>> 5|POINT(1 5)
>> 6|POINT(1.5 1.5)
>> \.
=> SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons') OVER (PARTITION BEST)
 AS (point_id, polygon_gid)
 FROM points;
 point_id | polygon_gid
-----+-----
 5 | 14
 1 | 14
 1 | 10
 4 | 14
 4 | 11
 6 | 12
 6 | 14
 6 | 11
 2 | 14
 2 | 11
 3 | 12
 3 | 14
(12 rows)

```

You can improve query performance by using the STV\_Intersect transform function in a WHERE clause. Performance improves because this syntax eliminates all points that do not intersect polygons in the index.

Return the count of points that intersect with the polygon, where gid = 14:

```

=> SELECT COUNT(pt_id) FROM
 (SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons')
 OVER (PARTITION BEST) AS (pt_id, pol_id) FROM points)
 AS T WHERE pol_id = 14;
COUNT

 6
(1 row)

```

- [STV\\_Create\\_Index](#)
- [STV\\_Intersect scalar function](#)

## STV\_IsValidReason

Determines if a spatial object is well formed or valid. If the object is not valid, STV\_IsValidReason returns a string that explains where the invalidity occurs.

A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior that do not have more than one point touching the boundary of the exterior polygon.

If you pass an invalid object to a Vertica Place function, the function fails or returns incorrect results. To determine if a polygon is valid, first run ST\_IsValid. ST\_IsValid returns TRUE if the polygon is valid, FALSE otherwise.

### Note

If you pass a valid polygon to STV\_IsValidReason, it returns NULL.

Behavior type

[Immutable](#)

Syntax

```
STV_IsValidReason(g)
```

Arguments

**g**

Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84).

Returns

LONG VARCHAR

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	Yes
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

Examples

The following example shows how to use STV\_IsValidReason.

Returns a string describing where the polygon is invalid:

```
=> SELECT STV_IsValidReason(ST_GeomFromText('POLYGON((1 3,3 2,1 1,
3 0,1 0,1 3))'));
 STV_IsValidReason
```

```

Ring Self-intersection at or near POINT (1 1)
(1 row)
```

See also

[ST\\_IsValid](#)

STV\_LineStringPoint

Retrieves the vertices of a linestring or multilinestring. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object's type. GEOMETRY points inherit the SRID of the input object.

STV\_LineStringPoint is an analytic function. For more information, see [Analytic functions](#).

Behavior type

[Immutable](#)

Syntax

```
STV_LineStringPoint(g)
OVER([PARTITION NODES]) AS
```

Arguments

***g***

Linestring or multilinestring, value of type GEOMETRY or GEOGRAPHY

Returns

GEOMETRY or GEOGRAPHY

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use STV\_LineStringPoint.

Returns the vertices of the geometry linestring and their SRID:

```
=> SELECT ST_AsText(Point), ST_SRID(Point)
FROM (SELECT STV_LineStringPoint(
 ST_GeomFromText('MULTILINESTRING((1 2, 2 3, 3 1, 4 2),
 (10 20, 20 30, 30 10, 40 20))', 4269)) OVER () AS Point) AS foo;
ST_AsText | ST_SRID
-----+-----
POINT (1 2) | 4269
POINT (2 3) | 4269
POINT (3 1) | 4269
POINT (4 2) | 4269
POINT (10 20) | 4269
POINT (20 30) | 4269
POINT (30 10) | 4269
POINT (40 20) | 4269
(8 rows)
```

Returns the vertices of the geography linestring:

```
=> SELECT ST_AsText(g)
FROM (SELECT STV_LineStringPoint(
 ST_GeographyFromText('MULTILINESTRING ((42.1 71.0, 41.4 70.0, 41.3 72.9),
 (42.99 71.46, 44.47 73.21)', 4269)) OVER () AS g) AS line_geog_points;
ST_AsText

POINT (42.1 71.0)
POINT (41.4 70.0)
POINT (41.3 72.9)
POINT (42.99 71.46)
POINT (44.47 73.21)
(5 rows)
```

See also

[STV\\_PolygonPoint](#)

STV\_MemSize

Returns the length of the spatial object in bytes as an INTEGER.

Use this function to determine the optimal column width for your spatial data.

Behavior type

[Immutable](#)

Syntax

```
STV_MemSize(g)
```

Arguments

***g***  
 Spatial object, value of type GEOMETRY or GEOGRAPHY

Returns

INTEGER

Examples

The following example shows how you can optimize your table by sizing the GEOMETRY or GEOGRAPHY column to the maximum value returned by STV\_MemSize:

```

=> CREATE TABLE mem_size_table (id int, geom geometry(800));
CREATE TABLE
=> COPY mem_size_table (id, gx filler LONG VARCHAR, geom as ST_GeomFromText(gx)) FROM STDIN DELIMITER '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POINT(3 5)
>>2|MULTILINESTRING(((1 5, 2 4, 5 3, 6 6),(3 5, 3 7))
>>3|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT max(STV_MemSize(geom)) FROM mem_size_table;
max

336
(1 row)

=> CREATE TABLE production_table(id int, geom geometry(336));
CREATE TABLE
=> INSERT INTO production_table SELECT * FROM mem_size_table;
OUTPUT

3
(1 row)
=> DROP mem_size_table;
DROP TABLE

```

## STV\_NN

Calculates the distance of spatial objects from a reference object and returns (object, distance) pairs in ascending order by distance from the reference object.

Parameters **g1** and **g2** must be both GEOMETRY objects or both GEOGRAPHY objects.

STV\_NN is an analytic function. For more information, see [Analytic functions](#).

Behavior type

[Immutable](#)

Syntax

```
STV_NN(g, ref_obj, k) OVER()
```

Arguments

**g**  
Spatial object, value of type GEOMETRY or GEOGRAPHY

**ref\_obj**  
Reference object, type GEOMETRY or GEOGRAPHY

**k**  
Number of rows to return, type INTEGER

Returns

(Object, distance) pairs, in ascending order by distance. If a parameter is EMPTY or NULL, then 0 rows are returned.

Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes

Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

## Examples

The following example shows how to use STV\_NN.

Create a table and insert nine GEOGRAPHY points:

```
=> CREATE TABLE points (g geography);
CREATE TABLE
=> COPY points (gx filler LONG VARCHAR, g AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> POINT (21.5 18.4)
>> POINT (21.5 19.2)
>> POINT (21.5 20.7)
>> POINT (22.5 16.4)
>> POINT (22.5 17.15)
>> POINT (22.5 18.33)
>> POINT (23.5 13.68)
>> POINT (23.5 15.9)
>> POINT (23.5 18.4)
>> \.
```

Calculate the distances (in meters) of objects in table `points` from the GEOGRAPHY point (23.5, 20).

Returns the five objects that are closest to that point:

```
=> SELECT ST_AsText(nn), dist FROM (SELECT STV_NN(g,
 ST_GeographyFromText('POINT(23.5 20)'),5) OVER() AS (nn,dist) FROM points) AS example;
 ST_AsText | dist
-----+-----
POINT (23.5 18.4) | 177912.12757541
POINT (22.5 18.33) | 213339.210738322
POINT (21.5 20.7) | 222561.43679943
POINT (21.5 19.2) | 227604.371833335
POINT (21.5 18.4) | 275239.416790128
(5 rows)
```

## STV\_PolygonPoint

Retrieves the vertices of a polygon as individual points. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object's type. GEOMETRY points inherit the SRID of the input object.

STV\_PolygonPoint is an analytic function. For more information, see [Analytic functions](#).

### Behavior type

[Immutable](#)

### Syntax

```
STV_PolygonPoint(g)
OVER([PARTITION NODES]) AS
```

### Arguments

**g**  
Polygon, value of type GEOMETRY or GEOGRAPHY

### Returns

GEOMETRY or GEOGRAPHY

### Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

## Examples

The following examples show how to use STV\_PolygonPoint.

Returns the vertices of the geometry polygon:

```
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeomFromText('POLYGON((1 2, 2 3, 3 1, 1 2)))')
 OVER (PARTITION NODES) AS g) AS poly_points;
 ST_AsText

POINT (1 2)
POINT (2 3)
POINT (3 1)
POINT (1 2)
(4 rows)
```

Returns the vertices of the geography polygon:

```
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeographyFromText('
 POLYGON((25.5 28.76, 28.83 29.13, 27.2 30.99, 25.5 28.76)))')
 OVER (PARTITION NODES) AS g) AS poly_points;
 ST_AsText

POINT (25.5 28.76)
POINT (28.83 29.13)
POINT (27.2 30.99)
POINT (25.5 28.76)
(4 rows)
```

See also

[STV\\_LineStringPoint](#)

[STV\\_Refresh\\_Index](#)

Appends newly added or updated polygons and removes deleted polygons from an existing spatial index.

The OVER() clause must be empty.

Behavior type

Mutable

Syntax

```

STV_Refresh_Index(gid, g
 USING PARAMETERS index='index_name'
 [, skip_nonindexable_polygons={ true | false }])

OVER()
 [AS (type, polygons, srid, min_x, min_y, max_x, max_y, info,
indexed, appended, updated, deleted)]

```

#### Arguments

##### ***gid***

Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.

##### ***g***

Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.

#### Parameters

##### **index = 'index\_name'**

Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.

##### **skip\_nonindexable\_polygons = { true | false }**

(Optional) BOOLEAN

In rare cases, intricate polygons (for instance, with too high resolution or anomalous spikes) cannot be indexed. These polygons are considered non-indexable. When set to False, non-indexable polygons cause the index creation to fail. When set to True, index creation can succeed by excluding non-indexable polygons from the index.

To review the polygons that were not able to be indexed, use STV\_Describe\_Index with the parameter list\_polygon.

Default: False

#### Returns

##### ***type***

Spatial object type of the index.

##### ***polygons***

Number of polygons indexed.

##### ***SRID***

Spatial reference system identifier.

##### ***min\_x*, *min\_y*, *max\_x*, *max\_y***

Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (*min\_x*, *min\_y*) are the south-west coordinates, and (*max\_x*, *max\_y*) are the north-east coordinates.

##### ***info***

Lists the number of excluded spatial objects as well as their type that were excluded from the index.

##### ***indexed***

Number of polygons indexed during the operation.

##### ***appended***

Number of appended polygons.

##### ***updated***

Number of updated polygons.

##### ***deleted***

Number of deleted polygons.

#### Supported data types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	No	No
Multipoint	No	No

Linestring	No	No
Multilinestring	No	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

### Privileges

Any user with access to the STV\_\*\_Index functions can describe, rename, or drop indexes created by any other user.

### Limitations

- In rare cases, intricate polygons (such as those with too-high a resolution or anomalous spikes) cannot be indexed. See the parameter [skip\\_nonindexable\\_polygons](#) .
- If you replace a valid polygon in the source table with an invalid polygon, STV\_Refresh\_Index ignores the invalid polygon. As a result, the polygon originally indexed persists in the index.
- The following geometries cannot be indexed:
  - Non-polygons
  - NULL gid
  - NULL (multi) polygon
  - EMPTY (multi) polygon
  - Invalid (multi) polygon
- The following geographies are excluded from the index:
  - Polygons with holes
  - Polygons crossing the International Date Line
  - Polygons covering the north or south pole
  - Antipodal polygons

### Usage tips

- To cancel an STV\_Refresh\_Index run, use **Ctrl + C** .
- If you use source data not previously associated with the index, then the index will be overwritten.
- If STV\_Refresh\_Index has insufficient memory to process the query, then rebuild the index using STV\_Create\_Index.
- If there are no valid polygons in the geom column, STV\_Refresh\_Index reports an error in vertica.log and stops the index refresh.
- Ensure that all of the polygons you plan to index are valid polygons. STV\_Create\_Index and STV\_Refresh\_Index do not check polygon validity when building an index.

For more information, see [Ensuring polygon validity before creating or refreshing an index](#) .

### Examples

The following examples show how to use STV\_Refresh\_Index.

Refresh an index with a single literal argument:

```
=> SELECT STV_Create_Index(1, ST_GeomFromText('POLYGON((0 0,0 15.2,3.9 15.2,3.9 0,0 0))')
 USING PARAMETERS index='my_polygon') OVER();
type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 1 | 0 | 0 | 0 | 3.9 | 15.2 |
(1 row)

=> SELECT STV_Refresh_Index(2, ST_GeomFromText('POLYGON((0 0,0 13.2,3.9 18.2,3.9 0,0 0))')
 USING PARAMETERS index='my_polygon') OVER();
type | polygons | SRID | min_x | min_y | max_x | max_y | info | indexed | appended | updated | deleted
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 1 | 0 | 0 | 0 | 3.9 | 18.2 | | 1 | 1 | 0 | 1
(1 row)
```

Refresh an index from a table:

```

=> CREATE TABLE pols (gid INT, geom GEOMETRY);
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((5 20,9 30,20 45,36 35,5 20))
>> 3|POLYGON((12 23,9 30,20 45,36 35,37 67,45 80,50 20,12 23))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true)
OVER() FROM pols;
type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 3 | 0 | -36 | 20 | 50 | 80 |
(1 row)

=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 6|POLYGON((-32 74,8 70,8 50,-36 53,-32 74))
>> \.
=> SELECT STV_Refresh_Index(gid, geom USING PARAMETERS index='my_polygons_1') OVER() FROM pols;
type | polygons | SRID | min_x | min_y | max_x | max_y | info | indexed | appended | updated | deleted
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY | 4 | 0 | -36 | 20 | 50 | 80 | | 1 | 1 | 0 | 0
(1 row)

```

See also

- [STV\\_Create\\_Index](#)

- [STV\\_Drop\\_Index](#)
- [STV\\_Rename\\_Index](#)
- [Ensuring polygon validity before creating or refreshing an index](#)

## STV\_Rename\_Index

Renames a spatial index. If the index format is out of date, you cannot rename the index.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

Behavior type

[Immutable](#)

Syntax

```

STV_Rename_Index(USING PARAMETERS
 source = 'old_index_name',
 dest = 'new_index_name',
 overwrite = ['true' | 'false']
)
OVER ()

```

Arguments

**source = ' old\_index\_name '**

Current name of the spatial index, type VARCHAR.

**dest = ' new\_index\_name '**

New name of the spatial index, type VARCHAR.

**overwrite = [ 'true' | 'false' ]**

Boolean, whether to overwrite the index, if an index exists. This parameter cannot be NULL.

**Default:** False

### Privileges

Any user with access to the STV\_\*\_Index functions can describe, rename, or drop indexes created by any other user.

### Limitations

- Index names cannot exceed 110 characters.
- The backslash or tab characters are not allowed in index names.

### Examples

The following example shows how to use STV\_Rename\_Index.

Rename an index:

```
=> SELECT STV_Rename_Index (
 USING PARAMETERS
 source = 'my_polygons',
 dest = 'US_states',
 overwrite = 'false'
)
 OVER ();
rename_index

Index renamed
(1 Row)
```

### STV\_Reverse

Reverses the order of the vertices of a spatial object.

### Behavior type

[Immutable](#)

### Syntax

```
STV_Reverse(g, [USING PARAMETERS skip_nonreorientable_polygons={true | false}])
```

### Arguments

**g**

Spatial object, type GEOGRAPHY.

**skip\_nonreorientable\_polygons = { true | false }**

(Optional) Boolean

When set to False, non-orientable polygons generate an error. For example, if you use STV\_ForceLHR or STV\_Reverse with [skip\\_nonorientable\\_polygons](#) set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.

This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.

Vertica Place considers these polygons non-orientable:

- Polygons with a hole
- Multipolygons
- Multipolygons with a hole

**Default value** : False

### Returns

GEOGRAPHY

### Supported data types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No

Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	Yes	Yes
Multipolygon	No	Yes	Yes
GeometryCollection	No	No	No

## Examples

The following examples show how you can use STV\_Reverse.

Reverse vertices of a geography polygon:

```
=> SELECT ST_AsText(STV_Reverse(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1)'))));
 ST_AsText

POLYGON ((1 1, 2 2, 3 1, 1 1))
(1 row)
```

Force the polygon to reverse orientation:

```
=> SELECT ST_AsText(STV_Reverse(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1)'))));
 ST_AsText

POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

See also

[STV\\_ForceLHR](#)

[STV\\_SetExportShapefileDirectory](#)

Specifies the directory to export GEOMETRY or GEOGRAPHY data to a shapefile. The validity of the path is not checked, and the path cannot be empty.

Behavior type

[Immutable](#)

Syntax

```
STV_SetExportShapefileDirectory(USING PARAMETERS path='path')
```

Parameters

**path**

Destination path for the exported shapefile. The path can be on any shared [file system or object store](#).

Returns

The path of the shapefile export directory.

Privileges

Only a [superuser](#) can use this function.

Examples

The following example shows how you can use STV\_SetExportShapefileDirectory to set the shapefile export directory to /home/user/temp:

```
=> SELECT STV_SetExportShapefileDirectory(USING PARAMETERS path = '/home/user/temp');
 STV_SetExportShapefileDirectory

SUCCESS. Set shapefile export directory: [/home/user/temp]
(1 row)
```

[STV\\_ShpCreateTable](#)

Returns a [CREATE TABLE](#) statement with the columns and types of the attributes found in the specified shapefile.

The column types are sized according to the shapefile metadata. The size of the column is based on the largest geometry found in the shapefile. The first column in the table is named `gid`, which is an [IDENTITY](#) primary key column. The cache value is set to 64 by default. The last column is a GEOMETRY data type for storing the actual geometry data.

Behavior type

[Immutable](#)

Syntax

```
STV_ShpCreateTable (USING PARAMETERS file='filename') OVER()
```

Parameters

**file**

Fully qualified path of the `.dbf`, `.shp`, or `.shx` file. The path can be on any shared [file system or object store](#).

Returns

CREATE TABLE statement that matches the specified shapefile

Usage tips

- STV\_ShpCreateTable returns a CREATE TABLE statement; but it does not create the table. Modify the CREATE TABLE statement as needed, and then create the table before loading the shapefile into the table.
- To create a table with characters other than alphanumeric and underscore (`_`) characters, you must specify the table name enclosed in double quotes, such as `"counties%NY"`.
- The name of the table is the same as the name of the shapefile, without the directory name or extension.
- The shapefile must be accessible from the initiator node.
- If the `.shp` and `.shx` files are corrupt, STV\_ShpCreateTable returns an error. If the `.shp` and `.shx` files are valid, but the `.dbf` file is corrupt, STV\_ShpCreateTable ignores the `.dbf` file and does not create columns for that data.
- All the mandatory files ( `.dbf`, `.shp`, `.shx` ) must be in the same directory. If not, STV\_ShpCreateTable returns an error.
- If the `.dbf` component of a shapefile contains a Numeric attribute, this field's values may lose precision when the Vertica shapefile loader loads it into a table. The target field is a 64-bit FLOAT column, which can only represent about 15 significant digits. In a `.dbf` file, numeric fields can be up to 30 digits.

Vertica records all instances of shapefile values that are too long in the `vertica.log` file.

Examples

The following example shows how to use STV\_ShpCreateTable.

Returns a CREATE TABLE statement:

```
=> SELECT STV_ShpCreateTable
 (USING PARAMETERS file='/shapefiles/tl_2010_us_state10.shp')
 OVER() as create_table_states;
 create_table_states
```

```

CREATE TABLE tl_2010_us_state10(
 gid IDENTITY(64) PRIMARY KEY,
 REGION10 VARCHAR(2),
 DIVISION10 VARCHAR(2),
 STATEFP10 VARCHAR(2),
 STATENS10 VARCHAR(8),
 GEOID10 VARCHAR(2),
 STUSPS10 VARCHAR(2),
 NAME10 VARCHAR(100),
 LSAD10 VARCHAR(2),
 MTFCC10 VARCHAR(5),
 FUNCSTAT10 VARCHAR(1),
 ALAND10 INT8,
 AWATER10 INT8,
 INTPTLAT10 VARCHAR(11),
 INTPTLON10 VARCHAR(12),
 geom GEOMETRY(940845)
);
(18 rows)
```

See also

- [STV\\_ShpSource and STV\\_ShpParser](#)

STV\_ShpSource and STV\_ShpParser

These two functions work with [COPY](#) to parse and load geometries and attributes from a shapefile into a Vertica table, and convert them to the appropriate GEOMETRY data type. You must use these two functions together.

The following restrictions apply:

- An empty multipoint or an invalid multipolygon can not be loaded from a shapefile.
- If the `.dbf` component of a shapefile contains a numeric attribute, this field's values might lose precision when the Vertica Place shapefile loader loads it into a table. The target field is a 64-bit FLOAT column, which can only represent about 15 significant digits; in a `.dbf` file, Numeric fields can be up to 30 digits.

Rejected records are saved to [CopyErrorLogs](#) subdirectory, under the Vertica catalog directory.

Behavior type

[Immutable](#)

Syntax

```
COPY table(columnlist)
 WITH SOURCE STV_ShpSource
 (file = 'path'[, SRID=spatial-reference-identifier] [, flatten_2d={true | false }])
 PARSER STV_ShpParser()
```

Arguments

***table***

Name of the table in which to load the geometry data.

***columnlist***

Comma-delimited list of column names in the table that match fields in the external file. Run the CREATE TABLE command that [STV\\_ShpCreateTable](#) creates. When you do so, these columns correspond to the second through the second-to-last columns.

Parameters

**file**

Fully qualified path of a `.dbf` , `.shp` , or `.shx` file. The path can be on any shared [file system or object store](#).

## SRID

Specifies an integer spatial reference identifier (SRID) associated with the shape file.

## flatten\_2d

Specifies a BOOLEAN argument that excludes 3D or 4D coordinates during COPY commands:

- **true** : Excludes geometries with 3D or 4D coordinates before a COPY command.
- **false** : Causes the load to fail if a geometry with 3D or 4D coordinate is found.

**Default:** false

## Privileges

- Source shapefile: Read
- Shapefile directory: Execute

## COPY errors

The COPY command fails under one of the following conditions:

- The shapefile cannot be located or opened.
- The number of columns or the data types of the columns that STV\_ShpParser creates do not match the columns in the destination table. Use [STV\\_ShpCreateTable](#) to generate the appropriate CREATE TABLE command.
- One of the mandatory files is missing or cannot be opened. When opening a shapefile, you must have three files: **.dbf** , **.shp** , and **.shx** .

## STV\_ShpSource file corruption handling

- If the **.shp** and **.shx** files are corrupt, STV\_ShpSource returns an error.
- If the **.shp** and **.shx** files are valid, but the **.dbf** file is corrupt, STV\_ShpSource ignores the **.dbf** file and does not create columns for that data.

## Examples

```
=> COPY tl_2010_us_state10 WITH SOURCE
STV_ShpSource(file='/shapefiles/tl_2010_us_state10.shp', SRID=4269) PARSER STV_ShpParser();
```

## Hadoop functions

This section contains functions to manage interactions with Hadoop.

### In this section

- [CLEAR\\_HDFS\\_CACHES](#)
- [EXTERNAL\\_CONFIG\\_CHECK](#)
- [GET\\_METADATA](#)
- [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#)
- [HASH\\_EXTERNAL\\_TOKEN](#)
- [HCATALOGCONNECTOR\\_CONFIG\\_CHECK](#)
- [HDFS\\_CLUSTER\\_CONFIG\\_CHECK](#)
- [KERBEROS\\_HDFS\\_CONFIG\\_CHECK](#)
- [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#)
- [SYNC\\_WITH\\_HCATALOG\\_SCHEMA\\_TABLE](#)
- [VERIFY\\_HADOOP\\_CONF\\_DIR](#)

## CLEAR\_HDFS\_CACHES

Clears the configuration information copied from HDFS and any cached connections.

This function affects reads using the **hdfs** scheme in the following ways:

- This function flushes information loaded from configuration files copied from Hadoop (such as core-site.xml). These files are found on the path set by the HadoopConfDir configuration parameter.
- This function flushes information about which NameNode is active in a High Availability (HA) Hadoop cluster. Therefore, the first request to Hadoop after calling this function is slower than expected.

Vertica maintains a cache of open connections to NameNodes to reduce latency. This function flushes that cache.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
CLEAR_HDFS_CACHES ()
```

Privileges

Superuser

Examples

The following example clears the Hadoop configuration information:

```
=> SELECT CLEAR_HDFS_CACHES();
CLEAR_HDFS_CACHES

Cleared
(1 row)
```

See also

[Hadoop parameters](#)

EXTERNAL\_CONFIG\_CHECK

Tests the Hadoop configuration of a Vertica cluster. This function tests HDFS configuration files, HCatalog Connector configuration, and Kerberos configuration.

This function calls the following functions:

- [KERBEROS\\_CONFIG\\_CHECK](#)
- [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#)
- [HDFS\\_CLUSTER\\_CONFIG\\_CHECK](#)
- [HCATALOGCONNECTOR\\_CONFIG\\_CHECK](#)

If you call this function with an argument, it passes the argument to functions it calls that also take an argument.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
EXTERNAL_CONFIG_CHECK([what_to_test])
```

Arguments

***what\_to\_test***

A string specifying the authorities, nameservices, and/or HCatalog schemas to test. The format is a comma-separated list of "key=value" pairs, where keys are "authority", "nameservice", and "schema". The value is passed to all of the sub-functions; see those reference pages for details on how values are interpreted.

Privileges

This function does not require privileges.

Examples

The following example tests the configuration of only the nameservice named "ns1". Output has been omitted due to length.

```
=> SELECT EXTERNAL_CONFIG_CHECK('nameservice=ns1');
```

GET\_METADATA

Returns the metadata of a Parquet file. Metadata includes the number and sizes of row groups, column names, and information about chunks and compression. Metadata is returned as JSON.

This function inspects one file. Parquet data usually spans many files in a single directory; choose one. The function does not accept a directory name as an argument.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

## Behavior type

[Volatile](#)

Syntax

```
GET_METADATA('filename')
```

## Arguments

### **filename**

The name of a Parquet file. Any path that is valid for COPY is valid for this function. This function does not operate on files in other formats.

## Privileges

Superuser, or non-superuser with READ privileges on the USER-accessible storage location (see [GRANT \(storage location\)](#)).

## Examples

You must call this function with a single file, not a directory or glob:

```
=> SELECT GET_METADATA('/data/emp-row.parquet');
 GET_METADATA

schema:
required group field_id=-1 spark_schema {
 optional int32 field_id=-1 employeeID;
 optional group field_id=-1 personal {
 optional binary field_id=-1 name (String);
 optional group field_id=-1 address {
 optional binary field_id=-1 street (String);
 optional binary field_id=-1 city (String);
 optional int32 field_id=-1 zipcode;
 }
 optional int32 field_id=-1 taxID;
 }
 optional binary field_id=-1 department (String);
}

## HADOOP\_IMPERSONATION\_CONFIG\_CHECK

Reports the delegation tokens Vertica will use when accessing Kerberized data in HDFS. The HadoopImpersonationConfig configuration parameter specifies one or more authorities, nameservices, and HCatalog schemas and their associated tokens. For each tested value, the function reports what doAs user or delegation token Vertica will use for access. Use this function to confirm that you have defined your delegation tokens as you intended.

You can call this function with an argument to specify the authority, nameservice, or HCatalog schema to test, or without arguments to test all configured values.

This function does not check that you can use these delegation tokens to access HDFS.

See [Proxy users and delegation tokens](#) for more about impersonation.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

### Behavior type

[Volatile](#)

### Syntax

```
HADOOP_IMPERSONATION_CONFIG_CHECK([what_to_test])
```

### Arguments

#### ***what\_to\_test***

A string specifying the authorities, nameservices, and/or HCatalog schemas to test. For example, a value of 'nameservice=ns1' means the function tests only access to the nameservice "ns1" and ignores any other authorities and schemas. A value of 'nameservice=ns1, schema=hcat1' means the function tests one nameservice and one HCatalog schema.

If you do not specify this argument, the function tests all authorities, nameservices, and schemas defined in HadoopImpersonationConfig.

### Privileges

This function does not require privileges.

### Examples

Consider the following definition of HadoopImpersonationConfig:

```
[{
 "nameservice": "ns1",
 "token": "RANDOM-TOKEN-STRING"
},
{
 "nameservice": "*",
 "doAs": "Paul"
},
{
 "schema": "hcat1",
 "doAs": "Fred"
}
]
```

The following query tests only the "ns1" name service:

```
=> SELECT HADOOP_IMPERSONATION_CONFIG_CHECK('nameservice=ns1');

-- hadoop_impersonation_config_check --
Connections to nameservice [ns1] will use a delegation token with hash [b3dd9e71cd695d91]
```

This function returns a hash of the token for security reasons. You can call [HASH\\_EXTERNAL\\_TOKEN](#) with the expected value and compare that hash to the one in this function's output.

A query with no argument tests all values:

```
=> SELECT HADOOP_IMPERSONATION_CONFIG_CHECK();

-- hadoop_impersonation_config_check --
Connections to nameservice [ns1] will use a delegation token with hash [b3dd9e71cd695d91]
JDBC connections for HCatalog schema [hcat1] will doAs [Fred]
[!] hadoop_impersonation_config_check : [PASS]
```

## HASH\_EXTERNAL\_TOKEN

Returns a hash of a string token, for use with [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#). Call [HASH\\_EXTERNAL\\_TOKEN](#) with the delegation token you expect Vertica to use and compare it to the hash in the output of [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
HASH_EXTERNAL_TOKEN('token')
```

Arguments

### **token**

A string specifying the token to hash. The token is configured in the HadoopImpersonationConfig parameter.

Privileges

This function does not require privileges.

Examples

The following query tests the expected value shown in the example on the [HADOOP\\_IMPERSONATION\\_CONFIG\\_CHECK](#) reference page.

```
=> SELECT HASH_EXTERNAL_TOKEN('RANDOM-TOKEN-STRING');
hash_external_token

b3dd9e71cd695d91
(1 row)
```

## HCATALOGCONNECTOR\_CONFIG\_CHECK

Tests the configuration of a Vertica cluster that uses the HCatalog Connector to access Hive data. The function first verifies that the HCatalog

Connector is properly installed and reports on the values of several related configuration parameters. It then tests the connection using HiveServer2. This function does not support the WebHCat server.

If you specify an HCatalog schema, and if you have defined a delegation token for that schema, this function uses the delegation token. Otherwise, the function uses the default endpoint without a delegation token.

See [Proxy users and delegation tokens](#) for more about delegation tokens.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
HCATALOGCONNECTOR_CONFIG_CHECK(['what_to_test'])
```

Arguments

**what\_to\_test**

A string specifying the HCatalog schemas to test. For example, a value of 'schema=hcat1' means the function tests only the "hcat1" schema and ignores any others that are found.

Privileges

This function does not require privileges.

Examples

The following query tests with the default endpoint and no delegation token.

```
=> SELECT HCATALOGCONNECTOR_CONFIG_CHECK();

-- hcatalogconnector_config_check --

HCatalogConnectorUseHiveServer2 : [1]
EnableHCatImpersonation : [1]
HCatalogConnectorUseORCReader : [1]
HCatalogConnectorUseParquetReader : [1]
HCatalogConnectorUseTxtReader : [0]
[INFO] Vertica is not configured to use its internal parsers for delimited files.
[INFO] This is off by default, but will be changed in a future release.
HCatalogConnectorUseLibHDFSPP : [1]

[OK] HCatalog connector library is properly installed.
[INFO] Creating JDBC connection as session user.
[OK] Successful JDBC connection to HiveServer2 as user [USER].

[!] hcatalogconnector_config_check : [PASS]
```

To test with the configured delegation token, pass the schema as an argument:

```
=> SELECT HCATALOGCONNECTOR_CONFIG_CHECK('schema=hcat1');
```

**HDFS\_CLUSTER\_CONFIG\_CHECK**

Tests the configuration of a Vertica cluster that uses HDFS. The function scans the Hadoop configuration files found in HadoopConfDir and performs configuration checks on each cluster it finds. If you have more than one cluster configured, you can specify which one to test instead of testing all of them.

For each Hadoop cluster, it reports properties including:

- Nameservice name and associated NameNodes
- High-availability status
- RPC encryption status
- Kerberos authentication status
- HTTP(S) status

It then tests connections using [http\(s\)](#), [hdfs](#), and [webhdfs](#) URL schemes. It tests the latter two using both the Vertica and session user.

See [Configuring HDFS access](#) for information about configuration files and HadoopConfDir.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
HDFS_CLUSTER_CONFIG_CHECK(['what_to_test'])
```

Arguments

**what\_to\_test**

A string specifying the authorities or nameservices to test. For example, a value of 'nameservice=ns1' means the function tests only "ns1" cluster. If you specify both an authority and a nameservice, the authority must be a NameNode in the specified nameservice for the check to pass.

If you do not specify this argument, the function tests all cluster configurations found in HadoopConfDir.

Privileges

This function does not require privileges.

Examples

The following example tests all clusters.

```
=> SELECT HDFS_CLUSTER_CONFIG_CHECK();

-- hdfs_cluster_config_check --

Hadoop Conf Path : [/conf/hadoop_conf]
[OK] HadoopConfDir verified on all nodes
Connection Timeout (seconds) : [60]
Token Refresh Frequency (seconds) : [0]
HadoopFSBlockSizeBytes (MiB) : [64]

[OK] Found [1] hadoop cluster configurations

----- Cluster 1 -----
Is DefaultFS : [true]
Nameservice : [vmns]
Namenodes : [node1.example.com:8020, node2.example.com:8020]
High Availability : [true]
RPC Encryption : [false]
Kerberos Authentication : [true]
HTTPS Only : [false]
[INFO] Checking connections to [hdfs://]
vertica : [OK]
dbuser : [OK]

[INFO] Checking connections to [http://node1.example.com:50070]
[INFO] Node is in standby
[INFO] Checking connections to [http://node2.example.com:50070]
[OK] Can make authenticated external curl connection
[INFO] Checking webhdfs
vertica : [OK]
USER : [OK]

[!] hdfs_cluster_config_check : [PASS]
```

KERBEROS\_HDFS\_CONFIG\_CHECK

### Deprecated

This function is deprecated and will be removed in a future release. Instead, use [EXTERNAL\\_CONFIG\\_CHECK](#).

Tests the Kerberos configuration of a Vertica cluster that uses HDFS. The function succeeds if it can use both the Vertica keytab file and the session user to access HDFS, and reports errors otherwise. This function is a more specific version of [KERBEROS\\_CONFIG\\_CHECK](#).

If the current session is not Kerberized, this function will not be able to use secured HDFS connections and will fail.

You can call this function with arguments to specify an HDFS configuration to test, or without arguments. If you call it with no arguments, this function reads the HDFS configuration files and fails if it does not find them. See [Configuring HDFS access](#). If it finds configuration files, it tests all configured nameservices.

The function performs the following tests, in order:

- Are Kerberos services available?
- Does a keytab file exist and are the Kerberos and HDFS configuration parameters set in the database?
- Can Vertica read and invoke kinit with the keys to authenticate to HDFS and obtain the database Kerberos ticket?
- Can Vertica perform `hdfs` and `webhdfs` operations using both the database Kerberos ticket and user-forwardable tickets for the current session?
- Can Vertica connect to HiveServer2? (This function does not support WebHCat.)

If any test fails, the function returns a descriptive error message.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
KERBEROS_HDFS_CONFIG_CHECK(['hdfsHost:hdfsPort',
'webhdfsHost:webhdfsPort', 'webhcatHost'])
```

Arguments

***hdfsHost , hdfsPort***

The hostname or IP address and port of the HDFS NameNode. Vertica uses this server to access data that is specified with `hdfs` URLs. If the value is `'`, the function skips this part of the check.

***webhdfsHost , webhdfsPort***

The hostname or IP address and port of the WebHDFS server. Vertica uses this server to access data that is specified with `webhdfs` URLs. If the value is `'`, the function skips this part of the check.

***webhcatHost***

Pass any value in this position. WebHCat is deprecated and this value is ignored but must be present.

Privileges

This function does not require privileges.

**SYNC\_WITH\_HCATALOG\_SCHEMA**

Copies the structure of a Hive database schema available through the HCatalog Connector to a Vertica schema. If the HCatalog schema and the target Vertica schema have matching table names, `SYNC_WITH_HCATALOG_SCHEMA` overwrites the Vertica tables.

This function can synchronize the HCatalog schema directly. In this case, call it with the same schema name for the `vertica_schema` and `hcatalog_schema` parameters. The function can also synchronize a different schema to the HCatalog schema.

If you change the settings of [HCatalog Connector configuration parameters](#), you must call this function again.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SYNC_WITH_HCATALOG_SCHEMA(vertica_schema, hcatalog_schema, [drop_non_existent])
```

Parameters

***vertica\_schema***

The target Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as `hcatalog_schema`, or it can be a separate one created with [CREATE SCHEMA](#).

### Caution

Do not use the Vertica schema to store other data.

### *hcatalog\_schema*

The HCatalog schema to copy, created with [CREATE HCATALOG SCHEMA](#)

### *drop\_non\_existent*

If `true`, drop any tables in *vertica\_schema* that do not correspond to a table in *hcatalog\_schema*

### Privileges

Non-superuser: CREATE privileges on *vertica\_schema*.

Users also require access to Hive data, one of the following:

- USAGE permissions on *hcat\_schema*, if Hive does not use an authorization service to manage access.
- Permission through an authorization service (Sentry or Ranger), and access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)
- dbadmin user privileges, with or without an authorization service.

### Data type matching

Hive STRING and BINARY data types are matched, in Vertica, to the VARCHAR(65000) and VARBINARY(65000) types. Adjust the data types with [ALTER TABLE](#) as needed after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can cause mismatches between the two. To avoid data truncation, set values in Vertica based on bytes, not characters.

If data size exceeds the column size, Vertica logs an event at read time in the QUERY\_EVENTS system table.

### Examples

The following example uses SYNC\_WITH\_HCATALOG\_SCHEMA to synchronize an HCatalog schema named hcat:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
 HCATALOG_USER='hcatuser';
```

```
CREATE SCHEMA
```

```
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
```

```
sync_with_hcatalog_schema
```

```

Schema hcat synchronized with hcat
```

```
tables in hcat = 56
```

```
tables altered in hcat = 0
```

```
tables created in hcat = 56
```

```
stale tables in hcat = 0
```

```
table changes erred in hcat = 0
```

```
(1 row)
```

```
=> -- Use vsq!s \d command to describe a table in the synced schema
```

```
=> \d hcat.messages
```

```
List of Fields by Tables
```

```
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
```

```
-----+-----+-----+-----+-----+-----+-----+-----+-----
hcat | messages | id | int | 8 | | f | f | |
hcat | messages | userid | varchar(65000) | 65000 | | f | f | |
hcat | messages | "time" | varchar(65000) | 65000 | | f | f | |
hcat | messages | message | varchar(65000) | 65000 | | f | f | |
```

```
(4 rows)
```

The following example uses SYNC\_WITH\_HCATALOG\_SCHEMA followed by ALTER TABLE to adjust a column value:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
...
=> ALTER TABLE hcat.t ALTER COLUMN a1 SET DATA TYPE long varchar(1000000);
=> ALTER TABLE hcat.t ALTER COLUMN a2 SET DATA TYPE long varbinary(1000000);
```

The following example uses SYNC\_WITH\_HCATALOG\_SCHEMA with a local (non-HCatalog) schema:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> CREATE SCHEMA hcat_local;
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');
```

## SYNC\_WITH\_HCATALOG\_SCHEMA\_TABLE

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a Vertica table.

This function can synchronize the HCatalog schema directly. In this case, call it with the same schema name for the *vertica\_schema* and *hcatalog\_schema* parameters. The function can also synchronize a different schema to the HCatalog schema.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SYNC_WITH_HCATALOG_SCHEMA_TABLE(vertica_schema, hcatalog_schema, table_name)
```

Parameters

### *vertica\_schema*

The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as *hcatalog\_schema*, or it can be a separate one created with [CREATE SCHEMA](#).

### *hcatalog\_schema*

The HCatalog schema to copy, created with [CREATE\\_HCATALOG\\_SCHEMA](#).

### *table\_name*

The table in *hcatalog\_schema* to copy. If *table\_name* already exists in *vertica\_schema*, the function overwrites it.

Privileges

Non-superuser: CREATE privileges on *vertica\_schema*.

Users also require access to Hive data, one of the following:

- USAGE permissions on *hcat\_schema*, if Hive does not use an authorization service to manage access.
- Permission through an authorization service (Sentry or Ranger), and access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)
- dbadmin user privileges, with or without an authorization service.

Data type matching

Hive STRING and BINARY data types are matched, in Vertica, to the VARCHAR(65000) and VARBINARY(65000) types. Adjust the data types with [ALTER TABLE](#) as needed after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can cause mismatches between the two. To avoid data truncation, set values in Vertica based on bytes, not characters.

If data size exceeds the column size, Vertica logs an event at read time in the QUERY\_EVENTS system table.

Examples

The following example uses SYNC\_WITH\_HCATALOG\_SCHEMA\_TABLE to synchronize the "nation" table:

```

=> CREATE SCHEMA 'hcat_local';
CREATE SCHEMA

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='hcat'
 HCATALOG_USER='hcatuser';
CREATE SCHEMA

=> SELECT sync_with_hcatalog_schema_table('hcat_local', 'hcat', 'nation');
sync_with_hcatalog_schema_table

Schema hcat_local synchronized with hcat for table nation
table nation is created in schema hcat_local
(1 row)

```

The following example shows the behavior if the "nation" table already exists in the local schema:

```

=> SELECT sync_with_hcatalog_schema_table('hcat_local', 'hcat', 'nation');
sync_with_hcatalog_schema_table

Schema hcat_local synchronized with hcat for table nation
table nation is altered in schema hcat_local
(1 row)

```

## VERIFY\_HADOOP\_CONF\_DIR

Verifies that the Hadoop configuration that is used to access HDFS is valid on all Vertica nodes. The configuration is valid if:

- all required configuration files are found on the path defined by the HadoopConfDir configuration parameter
- all properties needed by Vertica are set in those files

This function does not attempt to validate the settings of those properties; it only verifies that they have values.

It is possible for Hadoop configuration to be valid on some nodes and invalid on others. The function reports a validation failure if the value is invalid on any node; the rest of the output reports the details.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
VERIFY_HADOOP_CONF_DIR()
```

Parameters

This function has no parameters.

Privileges

This function does not require privileges.

Examples

The following example shows the results when the Hadoop configuration is valid.

```

=> SELECT VERIFY_HADOOP_CONF_DIR();
verify_hadoop_conf_dir

Validation Success
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0002: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0003: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0004: HadoopConfDir [PG_TESTOUT/config] is valid
(1 row)

```

In the following example, the Hadoop configuration is valid on one node, but on other nodes a needed value is missing.

```
=> SELECT VERIFY_HADOOP_CONF_DIR();
verify_hadoop_conf_dir
```

#### Validation Failure

```
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/test_configs/config] is valid
v_vmart_node0002: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0003: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0004: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
(1 row)
```

## Machine learning functions

Machine learning functions let you work with your data set in different stages of the data analysis process:

- Preparing models
- Training models
- Evaluating models
- Applying models
- Managing models

Some Vertica machine learning functions are implemented as Vertica UDX functions, while others are implemented as meta-functions:

- A UDX function accepts an input relation name from a **FROM** clause. The **SELECT** statement that calls the functions is composable—it can be used as a sub-query in another **SELECT** statement.
- A meta-function accepts the input relation name as a single-quoted string passed to it as an argument or a named parameter. The data that the **SELECT** statement returns cannot be used in a sub-query. Machine learning meta-functions do not support temporary tables.

All machine learning functions automatically cast NUMERIC arguments to FLOAT.

### Important

Before using a machine learning function, be aware that any open transaction on the current session might be committed.

In this section

- [Data preparation](#)
- [Machine learning algorithms](#)
- [Model evaluation](#)
- [Model management](#)
- [Transformation functions](#)

### Data preparation

Vertica supports machine learning functions that prepare data as needed before subjecting it to analysis.

In this section

- [BALANCE](#)
- [CHI\\_SQUARED](#)
- [CORR\\_MATRIX](#)
- [DETECT\\_OUTLIERS](#)
- [IFOREST](#)
- [IMPUTE](#)
- [NORMALIZE](#)
- [NORMALIZE\\_FIT](#)
- [ONE\\_HOT\\_ENCODER\\_FIT](#)
- [PCA](#)
- [SUMMARIZE\\_CATCOL](#)
- [SUMMARIZE\\_NUMCOL](#)
- [SVD](#)

### BALANCE

Returns a view with an equal distribution of the input data based on the response\_column.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
BALANCE ('output-view', 'input-relation', 'response-column', 'balance-method'
[USING PARAMETERS sampling_ratio=ratio])
```

Arguments

#### **output-view**

The name of the view where Vertica saves the balanced data from the input relation.

#### **Note**

**Note** : The view that results from this function employs a random function. Its content can differ each time it is used in a query. To make the operations on the view predictable, store it in a regular table.

#### **input-relation**

The table or view that contains the data the function uses to create a more balanced data set. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

#### **response-column**

Name of the input column that represents the dependent variable, of type VARCHAR or INTEGER.

#### **balance-method**

Specifies a method to select data from the minority and majority classes, one of the following.

- **hybrid\_sampling** : Performs over-sampling and under-sampling on different classes so each class is equally represented.
- **over\_sampling** : Over-samples on all classes, with the exception of the most majority class, towards the most majority class's cardinality.
- **under\_sampling** : Under-samples on all classes, with the exception of the most minority class, towards the most minority class's cardinality.
- **weighted\_sampling** : An alias of **under\_sampling** .

Parameters

#### **ratio**

The desired ratio between the majority class and the minority class. This value has no effect when used with balance method **hybrid\_sampling** .

**Default:** 1.0

Privileges

Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

```
=> CREATE TABLE backyard_bugs (id identity, bug_type int, finder varchar(20));
```

```
CREATE TABLE
```

```
=> COPY backyard_bugs FROM STDIN;
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> 1|Ants
>> 1|Beetles
>> 3|Ladybugs
>> 3|Ants
>> 3|Beetles
>> 3|Caterpillars
>> 2|Ladybugs
>> 3|Ants
>> 3|Beetles
>> 1|Ladybugs
>> 3|Ladybugs
>> \.
```

```
=> SELECT bug_type, COUNT(bug_type) FROM backyard_bugs GROUP BY bug_type;
```

```
bug_type | COUNT
```

```
-----+-----
 2 | 1
 1 | 3
 3 | 7
(3 rows)
```

```
=> SELECT BALANCE('backyard_bugs_balanced', 'backyard_bugs', 'bug_type', 'under_sampling');
 BALANCE
```

```
-----+-----
Finished in 1 iteration
```

```
(1 row)
```

```
=> SELECT bug_type, COUNT(bug_type) FROM backyard_bugs_balanced GROUP BY bug_type;
```

```
-----+-----
 2 | 1
 1 | 2
 3 | 1
(3 rows)
```

See also

- [Balancing imbalanced data](#)

## CHI\_SQUARED

Computes the conditional chi-square independence test on two categorical variables to find the likelihood that the two variables are independent. To condition the independence test on another set of variables, you can partition the data on these variables using a [PARTITION BY](#) clause.

### Tip

If a categorical column is not of a [numeric data type](#), you can use the [HASH](#) function to convert it into a column of type INT, where each category is mapped to a unique integer. However, note that NULL values are hashed to zero, so they will be included in the test instead of skipped by the function.

This function is a [multi-phase transform function](#).

Syntax

```
CHI_SQUARED('x-column', 'y-column'
 [USING PARAMETERS param=value[,...]])
```

## Arguments

### **x-column , y-column**

Columns in the input relation to be tested for dependency with each other. These columns must contain categorical data in numeric format.

## Parameters

### **x\_cardinality**

Integer in the range [1, 20], the cardinality of *x-column* . If the cardinality of *x-column* is less than the default value of 20, setting this parameter can decrease the amount memory used by the function.

**Default:** 20

### **y\_cardinality**

Integer in the range [1, 20], the cardinality of *y-column* . If the cardinality of *y-column* is less than the default value of 20, setting this parameter can decrease the amount memory used by the function.

**Default:** 20

### **alpha**

Float in the range (0.0, 1.0), the significance level. If the returned **pvalue** is less than this value, the null hypothesis, which assumes the variables are independent, is rejected.

**Default:** 0.05

## Returns

The function returns two values:

- **pvalue** (float): the confidence that the two variables are independent. If this value is greater than the **alpha** parameter value, the null hypothesis is accepted and the variables are considered independent.
- **independent** (boolean): true if the variables are independent; otherwise, false.

## Privileges

SELECT privileges on the input relation

## Examples

The following examples use the **titanic** dataset from the machine learning example data. If you have not downloaded these datasets, see [Download the machine learning example data](#) for instructions.

The **titanic\_training** table contains data related to passengers on the Titanic, including:

- **pclass** : the ticket class of the passenger, ranging from 1st class to 3rd class
- **survived** : whether the passenger survived, where 1 is yes and 0 is no
- **gender** : gender of the passenger
- **sibling\_and\_spouse\_count** : number of siblings aboard the Titanic
- **embarkation\_point** : port of embarkation

To test whether the survival of a passenger is dependent on their ticket class, run the following chi-square test:

```
=> SELECT CHI_SQUARED(pclass, survived USING PARAMETERS x_cardinality=3, y_cardinality=2, alpha=0.05) OVER() FROM titanic_training;
pvalue | independent

0 | f
(1 row)
```

With a returned **pvalue** of zero, the null hypothesis is rejected and you can conclude that the **survived** and **pclass** variables are dependent. To test whether this outcome is conditional on the gender of the passenger, partition by the **gender** column in the OVER clause:

```
=> SELECT CHI_SQUARED(pclass, survived USING PARAMETERS x_cardinality=3, y_cardinality=2) OVER(PARTITION BY gender) FROM titanic;
pvalue | independent

0 | f
(1 row)
```

As the **pvalue** is still zero, it is clear that the dependence of the **pclass** and **survived** variables is not conditional on the gender of the passenger.

If one of the categorical columns that you want to test is not a numeric type, use the **HASH** function to convert it into type INT:

```

-> SELECT CHI_SQUARED(sibling_and_spouse_count, HASH(embarkation_point) USING PARAMETERS alpha=0.05) OVER() FROM titanic_training;
 pvalue | independent
-----+-----
0.0753039994044853 | 1
(1 row)

```

The returned **pvalue** is greater than **alpha** , meaning the null hypothesis is accepted and the **sibling\_and\_spouse\_count** and **embarkation\_point** are independent.

## CORR\_MATRIX

Takes an input relation with numeric columns, and calculates the *Pearson Correlation Coefficient* between each pair of its input columns. The function is implemented as a Multi-Phase Transform function.

### Syntax

```
CORR_MATRIX (input-columns) OVER()
```

### Arguments

#### **input-columns**

A comma-separated list of the columns in the input table. The input columns can be of any numeric type or BOOL, but they will be converted internally to FLOAT. The number of input columns must be more than 1 and not more than 1600.

### Returns

CORR\_MATRIX returns the correlation matrix in triplet format. That is, each pair-wise correlation is identified by three returned columns: name of the first variable, name of the second variable, and the correlation value of the pair. The function also returns two extra columns: **number\_of\_ignored\_input\_rows** and **number\_of\_processed\_input\_rows** . The value of the fourth/fifth column indicates the number of rows from the input which are ignored/used to calculate the corresponding correlation value. Any input pair with NULL, Inf, or NaN is ignored.

The correlation matrix is symmetric with a value of 1 on all diagonal elements; therefore, it can return only the value of elements above the diagonals—that is, the upper triangle. Nevertheless, the function returns the entire matrix to simplify any later operations. Then, the number of output rows is:

```
(#input-columns)^2
```

The first two output columns are of type VARCHAR(128), the third one is of type FLOAT, and the last two are of type INT.

### Notes

- The contents of the OVER clause must be empty.
- The function returns no rows when the input table is empty.
- When any of  $X_i$  and  $Y_i$  is NULL, Inf, or NaN, the pair will not be included in the calculation of CORR(X, Y). That is, any input pair with NULL, Inf, or NaN is ignored.
- For the pair of (X,X), regardless of the contents of X: CORR(X,X) = 1, number\_of\_ignored\_input\_rows = 0, and number\_of\_processed\_input\_rows = #input\_rows.
- When  $(N \text{ SUMX}^2 == \text{SUMX} \text{ SUMX})$  or  $(N \text{ SUMY}^2 == \text{SUMY} \text{ SUMY})$  then value of CORR(X, Y) will be NULL. In theory it can happen in case of a column with constant values; nevertheless, it may not be always observed because of rounding error.
- In the special case where all pair values of  $(X_i, Y_i)$  contain NULL, inf, or NaN, and  $X \neq Y$ : CORR(X,Y)=NULL.

### Examples

The following example uses the [iris](#) dataset.\*

```

SELECT CORR_MATRIX("Sepal.Length", "Sepal.Width", "Petal.Length", "Petal.Width") OVER() FROM iris;
variable_name_1 | variable_name_2 | corr_value | number_of_ignored_input_rows | number_of_processed_input_rows
-----+-----+-----+-----+-----+
Sepal.Length | Sepal.Width | -0.117569784133002 | 0 | 150
Sepal.Width | Sepal.Length | -0.117569784133002 | 0 | 150
Sepal.Length | Petal.Length | 0.871753775886583 | 0 | 150
Petal.Length | Sepal.Length | 0.871753775886583 | 0 | 150
Sepal.Length | Petal.Width | 0.817941126271577 | 0 | 150
Petal.Width | Sepal.Length | 0.817941126271577 | 0 | 150
Sepal.Width | Petal.Length | -0.42844010433054 | 0 | 150
Petal.Length | Sepal.Width | -0.42844010433054 | 0 | 150
Sepal.Width | Petal.Width | -0.366125932536439 | 0 | 150
Petal.Width | Sepal.Width | -0.366125932536439 | 0 | 150
Petal.Length | Petal.Width | 0.962865431402796 | 0 | 150
Petal.Width | Petal.Length | 0.962865431402796 | 0 | 150
Sepal.Length | Sepal.Length | 1 | 0 | 150
Sepal.Width | Sepal.Width | 1 | 0 | 150
Petal.Length | Petal.Length | 1 | 0 | 150
Petal.Width | Petal.Width | 1 | 0 | 150
(16 rows)

```

## DETECT\_OUTLIERS

Returns the outliers in a data set based on the outlier threshold. The output is a table that contains the outliers. **DETECT\_OUTLIERS** uses the detection method **robust\_score** to normalize each input column. The function then identifies as outliers all rows that contain a normalized value greater than the default or specified threshold.

### Note

You can calculate normalized column values with Vertica functions [NORMALIZE](#) and [NORMALIZE\\_FIT](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```

DETECT_OUTLIERS ('output-table', 'input-relation', 'input-columns', 'detection-method'
 [USING PARAMETERS
 [outlier_threshold = threshold]
 [, exclude_columns = 'excluded-columns']
 [, partition_columns = 'partition-columns']])

```

Arguments

**output-table**

The name of the table where Vertica saves rows that are outliers along the chosen `input_columns` . All columns are present in this table.

#### ***input-relation***

The table or view that contains outlier data. If the input relation is defined in Hive, use `SYNC_WITH_HCATALOG_SCHEMA` to sync the `hcatalog` schema, and then run the machine learning function.

#### ***input-columns***

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. Input columns must be of type `numeric` .

#### ***detection-method***

The outlier detection method to use, set to `robust_zscore` .

#### Parameters

##### **outlier\_threshold**

The minimum normalized value in a row that is used to identify that row as an outlier.

**Default:** 3.0

##### **exclude\_columns**

Comma-separated list of column names from `input-columns` to exclude from processing.

##### **partition\_columns**

Comma-separated list of column names from the input table or view that defines the partitions. `DETECT_OUTLIERS` detects outliers among each partition separately.

**Default:** empty list

#### Privileges

##### Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output table

#### Examples

The following example shows how to use `DETECT_OUTLIERS` :

```
=> CREATE TABLE baseball_roster (id identity, last_name varchar(30), hr int, avg float);
```

```
CREATE TABLE
```

```
=> COPY baseball_roster FROM STDIN;
```

Enter data to be copied followed by a newline.

End with a backslash and a period on a line by itself.

```
>> Polo|7|.233
>> Gloss|45|.170
>> Gus|12|.345
>> Gee|1|.125
>> Laus|3|.095
>> Hilltop|16|.222
>> Wicker|78|.333
>> Scooter|0|.121
>> Hank|999999|.8888
>> Popup|35|.378
>> \.
```

```
=> SELECT * FROM baseball_roster;
```

```
id | last_name | hr | avg
-----+-----+-----
 3 | Gus | 12 | 0.345
 4 | Gee | 1 | 0.125
 6 | Hilltop | 16 | 0.222
10 | Popup | 35 | 0.378
 1 | Polo | 7 | 0.233
 7 | Wicker | 78 | 0.333
 9 | Hank |999999| 0.8888
 2 | Gloss | 45 | 0.17
 5 | Laus | 3 | 0.095
 8 | Scooter | 0 | 0.121
(10 rows)
```

```
=> SELECT DETECT_OUTLIERS('baseball_outliers', 'baseball_roster', 'id, hr, avg', 'robust_zscore' USING PARAMETERS
outlier_threshold=3.0);
```

```
DETECT_OUTLIERS
```

```

Detected 2 outliers
(1 row)
```

```
=> SELECT * FROM baseball_outliers;
```

```
id | last_name | hr | avg
-----+-----+-----
 7 | Wicker | 78 | 0.333
 9 | Hank |999999| 0.8888
(2 rows)
```

## IFOREST

Trains and returns an isolation forest (iForest) model. After you train the model, you can use the [APPLY\\_IFOREST](#) function to predict outliers in an input relation.

For more information about how the iForest algorithm works, see [Isolation Forest](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
IFOREST('model-name', 'input-relation', 'input-columns'[USING PARAMETERS param=value[...]])
```

## Arguments

### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

The table or view that contains the input data for IFOREST.

### **input-columns**

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. Columns must be of types CHAR, VARCHAR, BOOL, INT, or FLOAT.

Columns of types CHAR, VARCHAR, and BOOL are treated as categorical features; all others are treated as numeric features.

## Parameters

### **exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

**Default:** Empty string ("")

### **ntree**

Integer in the range [1, 1000], specifies the number of trees in the forest.

**Default:** 100

### **sampling\_size**

Float in the range (0.0, 1.0], specifies the portion of the input data set that is randomly picked, without replacement, for training each tree.

**Default:** 0.632

### **col\_sample\_by\_tree**

Float in the range (0.0, 1.0], specifies the fraction of columns that are randomly picked for training each tree.

**Default:** 1.0

### **max\_depth**

Integer in the range [1, 100], specifies the maximum depth for growing each tree.

**Default:** 10

### **nbins**

Integer in the range [2, 1000], specifies the number of bins used to discretize continuous features.

**Default:** 32

## Model Attributes

### **details**

Details about the function's predictor columns, including:

- **predictor** : Names of the predictors in the same order specified when training the model.
- **type** : Types of the predictors in the same order as their names in **predictor** .

### **tree\_count**

Number of trees in the model.

### **rejected\_row\_count**

Number of rows in *input-relation* that were skipped because they contained an invalid value.

### **accepted\_row\_count**

Total number of rows in *input-relation* minus **rejected\_row\_count** .

### **call\_string**

Value of all input arguments that were specified at the time the function was called.

## Privileges

### Non-superusers:

- CREATE privileges on the schema where the model is created

- SELECT privileges on the input relation

## Examples

In the following example, the input data to the function contains columns of type INT, VARCHAR, and FLOAT:

```
=> SELECT IFOREST('baseball_anomalies','baseball','team, hr, hits, avg, salary' USING PARAMETERS ntree=75, sampling_size=0.7,
max_depth=15);
IFOREST

Finished
(1 row)
```

You can verify that all the input columns were read in correctly by calling [GET\\_MODEL\\_SUMMARY](#) and checking the details section:

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='baseball_anomalies');
GET_MODEL_SUMMARY

=====
call_string
=====
SELECT iforest('public.baseball_anomalies', 'baseball', 'team, hr, hits, avg, salary' USING PARAMETERS exclude_columns="", ntree=75,
sampling_size=0.7, col_sample_by_tree=1, max_depth=15, nbins=32);

=====
details
=====
predictor| type
-----+-----
 team |char or varchar
 hr | int
 hits | int
 avg |float or numeric
 salary |float or numeric

=====
Additional Info
=====
 Name |Value
-----+-----
 tree_count | 75
rejected_row_count| 0
accepted_row_count|1000

(1 row)
```

See also

- [Detect outliers](#)
- [APPLY\\_IFOREST](#)
- [READ\\_TREE](#)

## IMPUTE

Imputes missing values in a data set with either the mean or the mode, based on observed values for a variable in each column. This function supports [numeric](#) and categorical data types.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
IMPUTE('output-view', 'input-relation', 'input-columns', 'method'
 [USING PARAMETERS [exclude_columns = 'excluded-columns'] [, partition_columns = 'partition-columns']])
```

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

## Arguments

### **output-view**

Name of the view that shows the input table with imputed values in place of missing values. In this view, rows without missing values are kept intact while the rows with missing values are modified according to the specified method.

### **input-relation**

The table or view that contains the data for missing-value imputation. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

### **input-columns**

Comma-separated list of input columns where missing values will be replaced, or asterisk (\*) to specify all columns. All columns must be of type [numeric](#) or BOOLEAN.

### **method**

The method to compute the missing value replacements, one of the following:

- **mean** : The missing values in each column will be replaced by the mean of that column. This method can be used for [numeric](#) data only.
- **mode** : The missing values in each column will be replaced by the most frequent value in that column. This method can be used for categorical data only.

## Parameters

### **exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

### **partition\_columns**

Comma-separated list of column names from the input relation that defines the partitions.

## Privileges

### Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output view schema

## Examples

Execute **IMPUTE** on the `small_input_impute` table, specifying the mean method:

```
=> SELECT impute('output_view','small_input_impute', 'pid, x1,x2,x3,x4','mean'
USING PARAMETERS exclude_columns='pid');
impute

Finished in 1 iteration
(1 row)
```

Execute **IMPUTE** , specifying the mode method:

```
=> SELECT impute('output_view3','small_input_impute', 'pid, x5,x6','mode' USING PARAMETERS exclude_columns='pid');
impute

Finished in 1 iteration
(1 row)
```

## See also

[Imputing missing values](#)

### NORMALIZE

Runs a normalization algorithm on an input relation. The output is a view with the normalized data.

### Note

**Note** : This function differs from `NORMALIZE_FIT`, which creates and stores a model rather than creating a view definition. This can lead to different performance characteristics between the two functions.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
NORMALIZE ('output-view', 'input-relation', 'input-columns', 'normalization-method'
 [USING PARAMETERS exclude_columns = 'excluded-columns'])
```

Arguments

**output-view**

The name of the view showing the input relation with normalized data replacing the specified input columns. .

**input-relation**

The table or view that contains the data to normalize. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

**input-columns**

Comma-separated list of [numeric](#) input columns that contain the values to normalize, or asterisk (\*) to select all columns.

**normalization-method**

The normalization method to use, one of the following:

- [minmax](#)
- [zscore](#)
- [robust\\_zscore](#)

If infinity values appear in the table, the method ignores those values.

Parameters

**exclude\_columns**

Comma-separated list of column names from [input-columns](#) to exclude from processing.

Privileges

Non-superusers:

- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

These examples show how you can use the NORMALIZE function on the `wt` and `hp` columns in the `mtcars` table.

Execute the NORMALIZE function, and specify the [minmax](#) method:

```
=> SELECT NORMALIZE('mtcars_norm', 'mtcars',
 'wt, hp', 'minmax');
 NORMALIZE

Finished in 1 iteration

(1 row)
```

Execute the NORMALIZE function, and specify the [zscore](#) method:

```
=> SELECT NORMALIZE('mtcars_normz', 'mtcars',
 'wt, hp', 'zscore');
 NORMALIZE

Finished in 1 iteration

(1 row)
```

Execute the NORMALIZE function, and specify the [robust\\_zscore](#) method:

```
=> SELECT NORMALIZE('mtcars_normz', 'mtcars',
 'wt, hp', 'robust_zscore');
NORMALIZE
```

Finished in 1 iteration

(1 row)

See also

[Normalizing data](#)

NORMALIZE\_FIT

#### Note

This function differs from [NORMALIZE](#), which directly outputs a view with normalized results, rather than storing normalization parameters into a model for later operation.

**NORMALIZE\_FIT** computes normalization parameters for each of the specified columns in an input relation. The resulting model stores the normalization parameters. For example, for **MinMax** normalization, the minimum and maximum value of each column are stored in the model. The generated model serves as input to functions [APPLY\\_NORMALIZE](#) and [REVERSE\\_NORMALIZE](#).

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
NORMALIZE_FIT ('model-name', 'input-relation', 'input-columns', 'normalization-method'
 [USING PARAMETERS [exclude_columns = 'excluded-columns'] [, output_view = 'output-view']])
```

Arguments

#### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

#### **input-relation**

The table or view that contains the data to normalize. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

#### **input-columns**

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. Input columns must be of data type [numeric](#).

#### **normalization-method**

The normalization method to use, one of the following:

- **minmax**
- **zscore**
- **robust\_zscore**

If you specify **robust\_zscore**, **NORMALIZE\_FIT** uses the function [APPROXIMATE\\_MEDIAN \[aggregate\]](#).

All normalization methods ignore infinity, negative infinity, or NULL values in the input relation.

Parameters

#### **exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

#### **output\_view**

Name of the view that contains all columns from the input relation, with the specified input columns normalized.

Model attributes

#### **data**

Normalization method set to **minmax** :

- **colNames** : Model column names

- **mins** : Minimum value of each column
- **maxes** : Maximum value of each column

## Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation
- CREATE privileges on the output view schema

## Examples

The following example creates a model with **NORMALIZE\_FIT** using the **wt** and **hp** columns in table **mtcars**, and then uses this model in successive calls to **APPLY\_NORMALIZE** and **REVERSE\_NORMALIZE**.

```
=> SELECT NORMALIZE_FIT('mtcars_normfit', 'mtcars', 'wt, hp', 'minmax');
NORMALIZE_FIT

Success
(1 row)
```

The following call to **APPLY\_NORMALIZE** specifies the **hp** and **cyl** columns in table **mtcars**, where **hp** is in the normalization model and **cyl** is not in the normalization model:

```
=> CREATE TABLE mtcars_normalized AS SELECT APPLY_NORMALIZE (hp, cyl USING PARAMETERS model_name = 'mtcars_normfit') FROM mtcars;
CREATE TABLE
=> SELECT * FROM mtcars_normalized;
 hp | cyl

[Normalizing data](#)

ONE\_HOT\_ENCODER\_FIT

Generates a sorted list of each of the category levels for each feature to be encoded, and stores the model.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
ONE_HOT_ENCODER_FIT ('model-name', 'input-relation', 'input-columns'
 [USING PARAMETERS
 [exclude_columns = 'excluded-columns']
 [, output_view = 'output-view']
 [, extra_levels = 'category-levels']])
```

Arguments

**model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

**input-relation**

The table or view that contains the data for one hot encoding. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

### **input-columns**

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. Input columns must be INTEGER, BOOLEAN, VARCHAR, or dates.

Parameters

### **exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

### **output\_view**

The name of the view that stores the input relation and the one hot encodings. Columns are returned in the order they appear in the input relation, with the one-hot encoded columns appended after the original columns.

### **extra\_levels**

Additional levels in each category that are not in the input relation. This parameter should be passed as a string that conforms with the JSON standard, with category names as keys, and lists of extra levels in each category as values.

Model attributes

### **call\_string**

The value of all input arguments that were specified at the time the function was called.

### **varchar\_categories integer\_categories boolean\_categories date\_categories**

Settings for all:

- **category\_name** : Column name
- **category\_level** : Levels of the category, sorted for each category
- **category\_level\_index** : Index of this categorical level in the sorted list of levels for the category.

Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation
- CREATE privileges on the output view schema

Examples

```
=> SELECT ONE_HOT_ENCODER_FIT ('one_hot_encoder_model','mtcars','*'
USING PARAMETERS exclude_columns='mpg,disp,drat,wt,qsec,vs,am');
ONE_HOT_ENCODER_FIT

Success
(1 row)
```

- [APPLY\\_ONE\\_HOT\\_ENCODER](#)
- [Encoding categorical columns](#)

PCA

Computes principal components from the input table/view. The results are saved in a PCA model. Internally, PCA finds the components by using SVD on the co-variance matrix built from the input data. The singular values of this decomposition are also saved as part of the PCA model. The signs of all elements of a principal component could be flipped all together on different runs.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
PCA ('model-name', 'input-relation', 'input-columns'
[USING PARAMETERS
 [exclude_columns = 'excluded-columns']
 [, num_components = num-components]
 [, scale = is-scaled]
 [, method = 'method']])
```

## Arguments

### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

The table or view that contains the input data for PCA.

### **input-columns**

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. All input columns must be a [numeric](#) data type.

## Parameters

### **exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

### **num\_components**

The number of components to keep in the model. If this value is not provided, all components are kept. The maximum number of components is the number of non-zero singular values returned by the internal call to SVD. This number is less than or equal to SVD (number of columns, number of rows).

### **scale**

A Boolean value that specifies whether to standardize the columns during the preparation step:

- **True** : Use a correlation matrix instead of a covariance matrix.
- **False** (default)

### **method**

The method used to calculate PCA, can be set to **LAPACK**.

## Model attributes

### **columns**

The information about columns from the input relation used for creating the PCA model:

- index
- name

### **singular\_values**

The information about singular values found. They are sorted in descending order:

- index
- value
- explained\_variance : percentage of the variance in data that can be attributed to this singular value
- accumulated\_explained\_variance : percentage of the variance in data that can be retained if we drop all singular values after this current one

### **principal\_components**

The principal components corresponding to the singular values mentioned above:

- index: indices of the elements in each component
- PC1
- PC2
- ...

### **counters**

The information collected during training the model, stored as name-value pairs:

- counter\_name
  - accepted\_row\_count: number of valid rows in the data
  - rejected\_row\_count: number of invalid rows (having NULL, INF or NaN) in the data
  - iteration\_count: number of iterations, always 1 for the current implementation of PCA
- counter\_value

### **call\_string**

The function call that created the model.

## Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation

Examples

```
=> SELECT PCA ('pcamodel', 'world','country,HDI,em1970,em1971,em1972,em1973,em1974,em1975,em1976,em1977,em1978,em1979,em1980,em1981,em1982,em1983,em1984 ,em1985,em1986,em1987,em1988,em1989,em1990,em1991,em1992,em1993,em1994,em1995,em1996,em1997,em1998,em1999,em2000,em2001,em2002,em2003,em2004,em2005,em2006,em2007,em2008,em2009,em2010,gdp1970,gdp1971,gdp1972,gdp1973,gdp1974,gdp1975,gdp1976,gdp1977,gdp1978,gdp1979,gdp1980,gdp1981,gdp1982,gdp1983,gdp1984,gdp1985,gdp1986,gdp1987,gdp1988,gdp1989,gdp1990,gdp1991,gdp1992,gdp1993,gdp1994,gdp1995,gdp1996,gdp1997,gdp1998,gdp1999,gdp2000,gdp2001,gdp2002,gdp2003,gdp2004,gdp2005,gdp2006,gdp2007,gdp2008,gdp2009,gdp2010' USING PARAMETERS exclude_columns='HDI,country');
```

SUMMARIZE\_CATCOL

Returns a statistical summary of categorical data input, in three columns:

- CATEGORY: Categorical levels, of the same SQL data type as the summarized column
- COUNT: The number of category levels, of type INTEGER
- PERCENT: Represents category percentage, of type FLOAT

Syntax

```
SUMMARIZE_CATCOL (target-column
 [USING PARAMETERS TOPK = topk-value [, WITH_TOTALCOUNT = show-total]])
OVER()
```

Arguments

*target-column*

The name of the input column to summarize, one of the following data types:

- BOOLEAN
- FLOAT
- INTEGER
- DATE
- CHAR/VARCHAR

Parameters

TOPK

Integer, specifies how many of the most frequent rows to include in the output.

### WITH\_TOTALCOUNT

A Boolean value that specifies whether the table contains a heading row that displays the total number of rows displayed in the target column, and a percent equal to 100.

**Default:** `true`

### Examples

This example shows the categorical summary for the `current_salary` column in the `salary_data` table. The output of the query shows the column category, count, and percent. The first column gives the categorical levels, with the same SQL data type as the input column, the second column gives a count of that value, and the third column gives a percentage.

```
=> SELECT SUMMARIZE_CATCOL (current_salary USING PARAMETERS TOPK = 5) OVER() FROM salary_data;
CATEGORY | COUNT | PERCENT
-----+-----+-----
 | 1000 | 100
39004 | 2 | 0.2
35321 | 1 | 0.1
36313 | 1 | 0.1
36538 | 1 | 0.1
36562 | 1 | 0.1
(6 rows)
```

### SUMMARIZE\_NUMCOL

Returns a statistical summary of columns in a Vertica table:

- Count
- Mean
- Standard deviation
- Min/max values
- Approximate percentile
- Median

All summary values are FLOAT data types, except INTEGER for count.

### Syntax

```
SUMMARIZE_NUMCOL (input-columns [USING PARAMETERS exclude_columns = 'excluded-columns']) OVER()
```

### Arguments

#### *input-columns*

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. All columns must be a [numeric](#) data type. If you select all columns, `SUMMARIZE_NUMCOL` normalizes all columns in the model

### Parameters

#### `exclude_columns`

Comma-separated list of column names from *input-columns* to exclude from processing.

### Examples

Show the statistical summary for the `age` and `salary` columns in the `employee` table:

```
=> SELECT SUMMARIZE_NUMCOL(* USING PARAMETERS exclude_columns='id,name,gender,title') OVER() FROM employee;
COLUMN | COUNT | MEAN | STDDEV | MIN | PERC25 | MEDIAN | PERC75 | MAX
-----+-----+-----+-----+-----+-----+-----+-----+-----
age | 5 | 63.4 | 19.3209730603818 | 44 | 45 | 67 | 71 | 90
salary | 5 | 3456.76 | 1756.78754300285 | 1234.56 | 2345.67 | 3456.78 | 4567.89 | 5678.9
(2 rows)
```

### SVD

Computes singular values (the diagonal of the S matrix) and right singular vectors (the V matrix) of an SVD decomposition of the input relation. The results are saved as an SVD model. The signs of all elements of a singular vector in SVD could be flipped all together on different runs.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
SVD ('model-name', 'input-relation', 'input-columns'
 [USING PARAMETERS
 [exclude_columns = 'excluded-columns']
 [, num_components = num-components]
 [, method = 'method']])
```

Arguments

**model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

**input-relation**

The table or view that contains the input data for SVD.

**input-columns**

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. Input columns must be a [numeric](#) data type.

Parameters

**exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

**num\_components**

The number of components to keep in the model. The maximum number of components is the number of non-zero singular values computed, which is less than or equal to min (number of columns, number of rows). If you omit this parameter, all components are kept.

**method**

The method used to calculate SVD, can be set to [LAPACK](#) .

Model attributes

**columns**

The information about columns from the input relation used for creating the SVD model:

- index
- name

**singular\_values**

The information about singular values found. They are sorted in descending order:

- index
- value
- explained\_variance : percentage of the variance in data that can be attributed to this singular value
- accumulated\_explained\_variance : percentage of the variance in data that can be retained if we drop all singular values after this current one

**right\_singular\_vectors**

The right singular vectors corresponding to the singular values mentioned above:

- index: indices of the elements in each vector
- vector1
- vector2
- ...

**counters**

The information collected during training the model, stored as name-value pairs:

- counter\_name
  - accepted\_row\_count: number of valid rows in the data
  - rejected\_row\_count: number of invalid rows (having NULL, INF or NaN) in the data
  - iteration\_count: number of iterations, always 1 for the current implementation of SVD
- counter\_value

## call\_string

The function call that created the model.

### Privileges

Non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation

### Examples

```
=> SELECT SVD ('svdmodel', 'small_svd', 'x1,x2,x3,x4');
SVD

Finished in 1 iterations.
Accepted Rows: 8 Rejected Rows: 0
(1 row)

=> CREATE TABLE transform_svd AS SELECT
 APPLY_SVD (id, x1, x2, x3, x4 USING PARAMETERS model_name='svdmodel', exclude_columns='id', key_columns='id')

### Machine learning algorithms

Vertica supports a full range of machine learning functions that train a model on a set of data, and return a model that can be saved for later execution.

These functions require the following privileges for non-superusers:

- CREATE privileges on the schema where the model is created
- SELECT privileges on the input relation

## Note

Machine learning algorithms contain a subset of four [classification](#) functions:

- [LOGISTIC\\_REG](#)
- [NAIVE\\_BAYES](#)
- [RF\\_CLASSIFIER](#)
- [SVM\\_CLASSIFIER](#)

In this section

- [ARIMA](#)
- [AUTOREGRESSOR](#)
- [BISECTING\\_KMEANS](#)
- [KMEANS](#)
- [KPROTOTYPES](#)
- [LINEAR\\_REG](#)
- [LOGISTIC\\_REG](#)
- [MOVING\\_AVERAGE](#)
- [NAIVE\\_BAYES](#)
- [PLS\\_REG](#)
- [POISSON\\_REG](#)
- [RF\\_CLASSIFIER](#)
- [RF\\_REGRESSOR](#)
- [SVM\\_CLASSIFIER](#)
- [SVM\\_REGRESSOR](#)
- [XGB\\_CLASSIFIER](#)
- [XGB\\_REGRESSOR](#)

## ARIMA

Creates and trains an autoregressive integrated moving average (ARIMA) model from a time series with consistent timesteps. ARIMA models combine the abilities of [AUTOREGRESSOR](#) and [MOVING\\_AVERAGE](#) models by making future predictions based on both preceding time series values and errors of previous predictions. ARIMA models also provide the option to apply a differencing operation to the input data, which can turn a non-stationary time series into a stationary time series. After the model is trained, you can make predictions with the [PREDICT\\_ARIMA](#) function.

In Vertica, ARIMA is implemented using a Kalman Filter state-space approach, similar to [Gardner, G., et al.](#) This approach updates the state-space model with each element in the training data in order to calculate a loss score over the training data. A [BFGS optimizer](#) is then used to adjust the coefficients, and the state-space estimation is rerun until convergence. Because of this repeated estimation process, ARIMA consumes large amounts of memory when called with high values of  $p$  and  $q$ .

Given that the input data must be sorted by timestamp, this algorithm is single-threaded.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Immutable](#)

Syntax

```
ARIMA('model-name', 'input-relation', 'timeseries-column', 'timestamp-column'
 USING PARAMETERS param=value[,...])
```

Arguments

### **model-name**

Model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

Name of the table or view containing *timeseries-column* and *timestamp-column*.

### **timeseries-column**

Name of a NUMERIC column in *input-relation* that contains the dependent variable or outcome.

### **timestamp-column**

Name of an INTEGER, FLOAT, or TIMESTAMP column in *input-relation* that represents the timestamp variable. The timestep between consecutive entries should be consistent throughout the *timestamp-column*.

#### Tip

If your *timestamp-column* has varying timesteps, consider standardizing the step size with the [TIME\\_SLICE](#) function.

#### Parameters

##### p

Integer in the range [0, 1000], the number of lags to include in the autoregressive component of the computation. If *q* is unspecified or set to zero, *p* must be set to a nonzero value. In some cases, using a large *p* value can result in a memory overload error.

#### Note

The [AUTOREGRESSOR](#) and [ARIMA](#) models use different training techniques that produce distinct models when trained with matching parameter values on the same data. For example, if you train an autoregressor model using the same data and *p* value as an ARIMA model trained with *d* and *q* parameters set to zero, those two models will not be identical.

**Default:** 0

##### d

Integer in the range [0, 10], the difference order of the model.

If the *timeseries-column* is a non-stationary time series, whose statistical properties change over time, you can specify a non-zero *d* value to difference the input data. This operation can remove or reduce trends in the time series data.

Differencing computes the differences between consecutive time series values and then trains the model on these values. The difference order *d*, where 0 implies no differencing, determines how many times to repeat the differencing operation. For example, second-order differencing takes the results of the first-order operation and differences these values again to obtain the second-order values. For an example that trains an ARIMA model that uses differencing, see [ARIMA model example](#).

**Default:** 0

##### q

Integer in the range [0, 1000], the number of lags to include in the moving average component of the computation. If *p* is unspecified or set to zero, *q* must be set to a nonzero value. In some cases, using a large *q* value can result in a memory overload error.

#### Note

The [MOVING\\_AVERAGE](#) and [ARIMA](#) models use different training techniques that produce distinct models when trained with matching parameter values on the same data. For example, if you train a moving-average model using the same data and *q* value as an ARIMA model trained with *p* and *d* parameters set to zero, those two models will not be identical.

**Default:** 0

#### missing

Method for handling missing values, one of the following strings:

- 'drop': Missing values are ignored.
- 'raise': Missing values raise an error.
- 'zero': Missing values are set to zero.
- 'linear\_interpolation': Missing values are replaced by a linearly interpolated value based on the nearest valid entries before and after the missing value. In cases where the first or last values in a dataset are missing, the function errors.

**Default:** 'linear\_interpolation'

#### init\_method

Initialization method, one of the following strings:

- 'Zero': Coefficients are initialized to zero.
- 'Hannan-Rissanen' or 'HR': Coefficients are initialized using the Hannan-Rissanen algorithm.

**Default:** 'Zero'

**epsilon**

Float in the range (0.0, 1.0), controls the convergence criteria of the optimization algorithm.

**Default:** 1e-6

**max\_iterations**

Integer in the range [1, 1000000), the maximum number of training iterations. If you set this value too low, the algorithm might not converge.

**Default:** 100

Model attributes

**coefficients**

Coefficients of the model:

- **phi** : parameters for the autoregressive component of the computation. The number of returned **phi** values is equal to the value of **p** .
- **theta** : parameters for the moving average component of the computation. The number of returned **theta** values is equal to the value of **q** .

**p, q, d**

ARIMA component values:

- **p** : number of lags included in the autoregressive component of the computation
- **d** : difference order of the model
- **q** : number of lags included in the moving average component of the computation

**mean**

The model mean, average of the accepted sample values from *timeseries-column*

**regularization**

Type of regularization used when training the model

**lambda**

Regularization parameter. Higher values indicates stronger regularization.

**mean\_squared\_error**

Mean squared error of the model on the training set

**rejected\_row\_count**

Number of samples rejected during training

**accepted\_row\_count**

Number of samples accepted for training from the data set

**timeseries\_name**

Name of the *timeseries-column* used to train the model

**timestamp\_name**

Name of the *timestamp-column* used to train the model

**missing\_method**

Method used for handling missing values

**call\_string**

SQL statement used to train the model

Examples

The function requires that at least one of the **p** and **q** parameters be a positive, nonzero integer. The following example trains a model where both of these parameters are set to two:

```
=> SELECT ARIMA('arima_temp', 'temp_data', 'temperature', 'time' USING PARAMETERS p=2, q=2);
 ARIMA

Finished in 24 iterations.
3650 elements accepted, 0 elements rejected.
(1 row)
```

To see a summary of the model, including all model coefficients and parameter values, call [GET\\_MODEL\\_SUMMARY](#) :

```
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='arima_temp');
 GET_MODEL_SUMMARY

## AUTOREGRESSOR

Creates and trains an autoregression (AR) or vector autoregression (VAR) model, depending on the number of provided value columns:

- One value column: the function executes autoregression and returns a trained AR model. AR is a univariate autoregressive time series algorithm that predicts a variable's future values based on its preceding values. The user specifies the number of lagged timesteps taken into account during computation, and the model then predicts future values as a linear combination of the values at each lag.
- Multiple value columns: the function executes vector autoregression and returns a trained VAR model. VAR is a multivariate autoregressive time series algorithm that captures the relationship between multiple time series variables over time. Unlike AR, which only considers a single variable, VAR models incorporate feedback between different variables in the model, enabling the model to analyze how variables interact across lagged time steps. For example, with two variables—atmospheric pressure and rain accumulation—a VAR model could determine whether a drop in pressure tends to result in rain at a future date.

To make predictions with a VAR or AR model, use the [PREDICT\\_AUTOREGRESSOR](#) function.

Because the input data must be sorted by timestamp, this function is single-threaded.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
AUTOREGRESSOR ('model-name', 'input-relation', 'value-columns', 'timestamp-column'
 [USING PARAMETERS param=value[...]])
```

Arguments

### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

The table or view containing *timestamp-column* and *value-columns*.

This algorithm expects a stationary time series as input; using a time series with a mean that shifts over time may lead to weaker results.

### **value-columns**

Comma-separated list of one or more NUMERIC input columns that contain the dependent variables or outcomes.

The number of value columns determines whether the function performs the autoregression (AR) or vector autoregression (VAR) algorithm. If only one input column is provided, the function executes autoregression. For multiple input columns, the function performs the VAR algorithm.

### **timestamp-column**

Name of an INTEGER, FLOAT, or TIMESTAMP column in *input-relation* that represents the timestamp variable. The timestep between consecutive entries must be consistent throughout the *timestamp-column*.

#### Tip

If your *timestamp-column* has varying timesteps, consider standardizing the step size with the [TIME\\_SLICE](#) function.

Parameters

**p**

INTEGER in the range [1, 1999], the number of lags to consider in the computation. Larger values for **p** weaken the correlation.

#### Note

The [AUTOREGRESSOR](#) and [ARIMA](#) models use different training techniques that produce distinct models when trained with matching parameter values on the same data. For example, if you train an autoregressor model using the same data and **p** value as an ARIMA model trained with **d** and **q** parameters set to zero, those two models will not be identical.

**Default:** 3

**method**

One of the following algorithms for training the model:

- 'OLS' (Ordinary Least Squares)
- 'Yule-Walker'

**Default:** 'OLS'

### missing

One of the following methods for handling missing values:

- 'drop': Missing values are ignored.
- 'error': Missing values raise an error.
- 'zero': Missing values are replaced with 0.
- 'linear\_interpolation': Missing values are replaced by linearly-interpolated values based on the nearest valid entries before and after the missing value. This means that in cases where the first or last values in a dataset are missing, they will simply be dropped. The VAR algorithm does not support linear interpolation.

The default method depends on the model type:

- AR: 'linear\_interpolation'
- VAR: 'error'

### regularization

For the OLS training method only, one of the following regularization methods used when fitting the data:

- None
- 'L2': Weight regularization term which penalizes the squared weight value

**Default:** None

### lambda

For the OLS training method only, FLOAT in the range [0, 100000], the regularization value, lambda.

**Default:** 1.0

### compute\_mse

BOOLEAN, whether to calculate and output the mean squared error (MSE).

**Default:** False

### subtract\_mean

BOOLEAN, whether the mean of each column in *value-columns* is subtracted from its column values before calculating the model coefficients. This parameter only applies if *method* is set to 'Yule-Walker'. If set to False, the model saves the column means as zero.

**Default:** False

### Examples

The following example creates and trains an autoregression model using the Yule-Walker training algorithm and a lag of 3:

```
=> SELECT AUTOREGRESSOR('AR_temperature_yw', 'temp_data', 'Temperature', 'time' USING PARAMETERS p=3, method='yule-walker');
 AUTOREGRESSOR

Finished. 3650 elements accepted, 0 elements rejected.

(1 row)
```

The following example creates and trains a VAR model with a lag of 2:

```
=> SELECT AUTOREGRESSOR('VAR_temperature', 'temp_data_VAR', 'temp_location1', 'temp_location2', 'time' USING PARAMETERS p=2);
WARNING 0: Only the Yule Walker method is currently supported for Vector Autoregression, setting method to Yule Walker
 AUTOREGRESSOR

Finished. 3650 elements accepted, 0 elements rejected.

(1 row)
```

See [Autoregressive model example](#) and [VAR model example](#) for extended examples that train and make predictions with AR and VAR models.

## BISECTING\_KMEANS

Executes the bisecting k-means algorithm on an input relation. The result is a trained model with a hierarchy of cluster centers, with a range of  $k$  values, each of which can be used for prediction.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
BISECTING_KMEANS('model-name', 'input-relation', 'input-columns', 'num-clusters'
 [USING PARAMETERS
 [exclude_columns = 'exclude-columns']
 [, bisection_iterations = bisection-iterations]
 [, split_method = 'split-method']
 [, min_divisible_cluster_size = min-cluster-size]
 [, kmeans_max_iterations = kmeans-max-iterations]
 [, kmeans_epsilon = kmeans-epsilon]
 [, kmeans_center_init_method = 'kmeans-init-method']
 [, distance_method = 'distance-method']
 [, output_view = 'output-view']
 [, key_columns = 'key-columns']])
```

Arguments

### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

Table or view that contains the input data for k-means. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

### **input-columns**

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. Input columns must be of data type [numeric](#).

### **num-clusters**

Number of clusters to create, an integer  $\leq 10,000$ . This argument represents the  $k$  in k-means.

Parameters

### **exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

### **bisection\_iterations**

Integer between 1 - 1MM inclusive, specifies number of iterations the bisecting k-means algorithm performs for each bisection step. This corresponds to how many times a standalone k-means algorithm runs in each bisection step.

A setting  $>1$  allows the algorithm to run and choose the best k-means run within each bisection step. If you use `kmeanspp`, the value of `bisection_iterations` is always 1, because `kmeanspp` is more costly to run but also better than the alternatives, so it does not require multiple runs.

**Default:** 1

### **split\_method**

The method used to choose a cluster to bisect/split, one of:

- `size` : Choose the largest cluster to bisect.
- `sum_squares` : Choose the cluster with the largest within-cluster sum of squares to bisect.

**Default:** `sum_squares`

### **min\_divisible\_cluster\_size**

Integer  $\geq 2$ , specifies minimum number of points of a divisible cluster.

**Default:** 2

## **kmeans\_max\_iterations**

Integer between 1 and 1MM inclusive, specifies the maximum number of iterations the k-means algorithm performs. If you set this value to a number lower than the number of iterations needed for convergence, the algorithm might not converge.

**Default:** 10

## **kmeans\_epsilon**

Integer between 1 and 1MM inclusive, determines whether the k-means algorithm has converged. The algorithm is considered converged after no center has moved more than a distance of *epsilon* from the previous iteration.

**Default:** 1e-4

## **kmeans\_center\_init\_method**

The method used to find the initial cluster centers in k-means, one of:

- **kmeanspp** (default): kmeans++ algorithm
- **pseudo** : Uses "pseudo center" approach used by Spark, bisects given center without iterating over points

## **distance\_method**

The measure for distance between two data points. Only Euclidean distance is supported at this time.

**Default:** **euclidean**

## **output\_view**

Name of the view where you save the assignment of each point to its cluster. You must have CREATE privileges on the view schema.

## **key\_columns**

Comma-separated list of column names that identify the output rows. Columns must be in the *input-columns* argument list. To exclude these and other input columns from being used by the algorithm, list them in parameter *exclude\_columns* .

Model attributes

## **centers**

A list of centers of the K centroids.

## **hierarchy**

The hierarchy of K clusters, including:

- ParentCluster: Parent cluster centroid of each centroid—that is, the centroid of the cluster from which a cluster is obtained by bisection.
- LeftChildCluster: Left child cluster centroid of each centroid—that is, the centroid of the first sub-cluster obtained by bisecting a cluster.
- RightChildCluster: the right child cluster centroid of each centroid—that is, the centroid of the second sub-cluster obtained by bisecting a cluster.
- BisectionLevel: Specifies which bisection step a cluster is obtained from.
- WithinSS: Within-cluster sum of squares for the current cluster
- TotalWithinSS: Total within-cluster sum of squares of leaf clusters thus far obtained.

## **metrics**

Several metrics related to the quality of the clustering, including

- Total sum of squares
- Total within-cluster sum of squares
- Between-cluster sum of squares
- Between-cluster sum of squares / Total sum of squares
- Sum of squares for cluster *x*, center\_id *y* [...]

Examples

```
SELECT BISECTING_KMEANS('myModel', 'iris1', '*', '5'
 USING PARAMETERS exclude_columns = 'Species,id', split_method = 'sum_squares', output_view = 'myBKmeansView');
```

See also

- [Clustering data hierarchically using bisecting k-means](#)
- [APPLY\\_BISECTING\\_KMEANS](#)

## KMEANS

Executes the k-means algorithm on an input relation. The result is a model with a list of cluster centers.

You can export the resulting k-means model in VERTICA\_MODELS or PMML format to apply it on data outside Vertica. You can also train a k-means model elsewhere, then import it to Vertica in PMML format to predict on data in Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
KMEANS ('model-name', 'input-relation', 'input-columns', 'num-clusters'
 [USING PARAMETERS
 [exclude_columns = 'excluded-columns']
 [, max_iterations = max-iterations]
 [, epsilon = epsilon-value]
 [, { init_method = 'init-method' } | { initial_centers_table = 'init-table' }]
 [, output_view = 'output-view']
 [, key_columns = 'key-columns']])
```

Arguments

#### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

#### **input-relation**

The table or view that contains the input data for k-means. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

#### **input-columns**

Comma-separated list of columns to use from the input relation, or asterisk (\*) to select all columns. Input columns must be of data type [numeric](#).

#### **num-clusters**

The number of clusters to create, an integer  $\leq 10,000$ . This argument represents the *k* in k-means.

Parameters

Important

Parameters *init\_method* and *initial\_centers\_table* are mutually exclusive. If you set both, the function returns an error.

#### **exclude\_columns**

Comma-separated list of column names from *input-columns* to exclude from processing.

#### **max\_iterations**

The maximum number of iterations the algorithm performs. If you set this value to a number lower than the number of iterations needed for convergence, the algorithm may not converge.

**Default:** 10

#### **epsilon**

Determines whether the algorithm has converged. The algorithm is considered converged after no center has moved more than a distance of 'epsilon' from the previous iteration.

**Default:** 1e-4

#### **init\_method**

The method used to find the initial cluster centers, one of the following:

- *random*
- *kmeanspp* (default): kmeans++ algorithm

This value can be memory intensive for high *k*. If the function returns an error that not enough memory is available, decrease the value of *k* or use the *random* method.

#### **initial\_centers\_table**

The table with the initial cluster centers to use. Supply this value if you know the initial centers to use and do not want Vertica to find the initial cluster centers for you.

#### **output\_view**

The name of the view where you save the assignments of each point to its cluster. You must have CREATE privileges on the schema where the view is saved.

#### **key\_columns**

Comma-separated list of column names from *input-columns* that will appear as the columns of *output\_view* . These columns should be picked such that their contents identify each input data point. This parameter is only used if *output\_view* is specified. Columns listed in *input-columns* that are only meant to be used as *key\_columns* and not for training should be listed in *exclude\_columns* .

Model attributes

#### **centers**

A list that contains the center of each cluster.

#### **metrics**

A string summary of several metrics related to the quality of the clustering.

Examples

The following example creates k-means model *myKmeansModel* and applies it to input table *iris1* . The call to *APPLY\_KMEANS* mixes column names and constants. When a constant is passed in place of a column name, the constant is substituted for the value of the column in all rows:

```
=> SELECT KMEANS('myKmeansModel', 'iris1', '*', 5
USING PARAMETERS max_iterations=20, output_view='myKmeansView', key_columns='id', exclude_columns='Species, id');
 KMEANS
```

```

Finished in 12 iterations
```

(1 row)

```
=> SELECT id, APPLY_KMEANS(Sepal_Length, 2.2, 1.3, Petal_Width
USING PARAMETERS model_name='myKmeansModel', match_by_pos='true') FROM iris2;
```

```
id | APPLY_KMEANS
```

```
-----+-----
```

```
5 | 1
10 | 1
14 | 1
15 | 1
21 | 1
22 | 1
24 | 1
25 | 1
32 | 1
33 | 1
34 | 1
35 | 1
38 | 1
39 | 1
42 | 1
```

```
...
```

(60 rows)

KPROTOTYPES

Executes the k-prototypes algorithm on an input relation. The result is a model with a list of cluster centers.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Syntax

```
SELECT KPROTOTYPES ('*'`model-name`*', '*'`input-relation`*', '*'`input-columns`*', '*'`num-clusters`*'
 [USING PARAMETERS [exclude_columns = '*'`exclude-columns`*']
 [, max_iterations = '*'`max-iterations`*']
 [, epsilon = '*'`epsilon`*']
 [, {[init_method = '*'`init-method`*'} | { initial_centers_table = '*'`init-table`*'}]
 [, gamma = '*'`gamma`*']
 [, output_view = '*'`output-view`*']
 [, key_columns = '*'`key-columns`*']);
```

Behavior type

[Volatile](#)

Arguments

**model-name**

Name of the model resulting from the training.

**input-relation**

Name of the table or view containing the training samples.

**input-columns**

String containing a comma-separated list of columns to use from the input-relation, or asterisk (\*) to select all columns.

**num-clusters**

Integer  $\leq 10,000$  representing the number of clusters to create. This argument represents the k in k-prototypes.

Parameters

**exclude-columns**

String containing a comma-separated list of column names from input-columns to exclude from processing.

**Default:** (empty)

**max\_iterations**

Integer  $\leq 1M$  representing the maximum number of iterations the algorithm performs.

**Default:** Integer  $\leq 1M$

**epsilon**

Integer which determines whether the algorithm has converged.

**Default:** 1e-4

**init\_method**

String specifying the method used to find the initial k-prototypes cluster centers.

**Default:** "random"

**initial\_centers\_table**

The table with the initial cluster centers to use.

**gamma**

Float between 0 and 10000 specifying the weighing factor for categorical columns. It can determine relative importance of numerical and categorical attributes

**Default:** Inferred from data.

**output\_view**

The name of the view where you save the assignments of each point to its cluster

**key\_columns**

Comma-separated list of column names that identify the output rows. Columns must be in the input-columns argument list

Examples

The following example creates k-prototypes model `small_model` and applies it to input table `small_test_mixed` :

```
=> SELECT KPROTOTYPES('small_model_initcenters', 'small_test_mixed', 'x0, country', 3 USING PARAMETERS
initial_centers_table='small_test_mixed_centers', key_columns='pid');
KPROTOTYPES

Finished in 2 iterations

(1 row)

=> SELECT country, x0, APPLY_KPROTOTYPES(country, x0
USING PARAMETERS model_name='small_model')
FROM small_test_mixed;
country | x0 | apply_kprototypes

## LINEAR\_REG

Executes linear regression on an input relation, and returns a linear regression model.

You can export the resulting linear regression model in VERTICA\_MODELS or PMML format to apply it on data outside Vertica. You can also train a linear regression model elsewhere, then import it to Vertica in PMML format to model on data inside Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
LINEAR_REG ('model-name', 'input-relation', 'response-column', 'predictor-columns'
[USING PARAMETERS
 [exclude_columns = 'excluded-columns']
 [, optimizer = 'optimizer-method']
 [, regularization = 'regularization-method']
 [, epsilon = epsilon-value]
 [, max_iterations = iterations]
 [, lambda = lamda-value]
 [, alpha = alpha-value]
 [, fit_intercept = boolean-value]])
```

Arguments

### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

Table or view that contains the training data for building the model. If the input relation is defined in Hive, use

[SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the `hcatalog` schema, and then run the machine learning function.

### **response-column**

Name of the input column that represents the dependent variable or outcome. All values in this column must be [numeric](#), otherwise the model is invalid.

### **predictor-columns**

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (\*) to select all columns. If you select all columns, the argument list for parameter `exclude_columns` must include `response-column`, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or `BOOLEAN`; otherwise the model is invalid.

#### **Note**

All `BOOLEAN` predictor values are converted to `FLOAT` values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a `BOOLEAN` predictor column in training, and during prediction provide a `FLOAT` column of the same name. In this case, all `FLOAT` values must be either 0 or 1.

### Parameters

#### **exclude\_columns**

Comma-separated list of columns from `predictor-columns` to exclude from processing.

#### **optimizer**

Optimizer method used to train the model, one of the following:

- [Newton](#)
- [BFGS](#)
- [CGD](#)

Important

If you select `CGD`, `regularization-method` must be set to `L1` or `ENet`, otherwise the function returns an error.

**Default:** `CGD` if `regularization-method` is set to `L1` or `ENet`, otherwise `Newton`.

#### **regularization**

Method of regularization, one of the following:

- `None` (default)
- `L1`
- `L2`
- `ENet`

#### **epsilon**

`FLOAT` in the range (0.0, 1.0), the error value at which to stop training. Training stops if either the difference between the actual and predicted values is less than or equal to `epsilon` or if the number of iterations exceeds `max_iterations`.

**Default:** 1e-6

#### **max\_iterations**

`INTEGER` in the range (0, 1000000), the maximum number of training iterations. Training stops if either the number of iterations exceeds `max_iterations` or if the difference between the actual and predicted values is less than or equal to `epsilon`.

**Default:** 100

#### **lambda**

Integer  $\geq 0$ , specifies the value of the `regularization` parameter.

**Default:** 1

#### **alpha**

Integer  $\geq 0$ , specifies the value of the `ENET regularization` parameter, which defines how much `L1` versus `L2` regularization to provide. A value of 1 is equivalent to `L1` and a value of 0 is equivalent to `L2`.

**Value range:** [0,1]

**Default:** 0.5

## fit\_intercept

Boolean, specifies whether the model includes an intercept. By setting to false, no intercept will be used in training the model. Note that setting `fit_intercept` to false does not work well with the BFGS optimizer.

**Default:** True

Model attributes

## data

The data for the function, including:

- `coeffNames` : Name of the coefficients. This starts with intercept and then follows with the names of the predictors in the same order specified in the call.
- `coeff` : Vector of estimated coefficients, with the same order as `coeffNames`
- `stdErr` : Vector of the standard error of the coefficients, with the same order as `coeffNames`
- `zValue` (for logistic regression): Vector of z-values of the coefficients, in the same order as `coeffNames`
- `tValue` (for linear regression): Vector of t-values of the coefficients, in the same order as `coeffNames`
- `pValue` : Vector of p-values of the coefficients, in the same order as `coeffNames`

## regularization

Type of regularization to use when training the model.

## lambda

Regularization parameter. Higher values enforce stronger regularization. This value must be nonnegative.

## alpha

Elastic net mixture parameter.

## iterations

Number of iterations that actually occur for the convergence before exceeding `max_iterations` .

## skippedRows

Number of rows of the input relation that were skipped because they contained an invalid value.

## processedRows

Total number of input relation rows minus `skippedRows` .

## callStr

Value of all input arguments specified when the function was called.

Examples

```
=> SELECT LINEAR_REG('myLinearRegModel', 'faithful', 'eruptions', 'waiting'
 USING PARAMETERS optimizer='BFGS', fit_intercept=true);
 LINEAR_REG

Finished in 10 iterations

(1 row)
```

## LOGISTIC\_REG

Executes logistic regression on an input relation. The result is a logistic regression model.

You can export the resulting logistic regression model in VERTICA\_MODELS or PMML format to apply it on data outside Vertica. You can also train a logistic regression model elsewhere, then import it to Vertica in PMML format to predict on data in Vertica.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

## Syntax

```
LOGISTIC_REG ('model-name', 'input-relation', 'response-column', 'predictor-columns'
 [USING PARAMETERS [exclude_columns = 'excluded-columns']
 [, optimizer = 'optimizer-method']
 [, regularization = 'regularization-method']
 [, epsilon = epsilon-value]
 [, max_iterations = iterations]
 [, lambda = lamda-value]
 [, alpha = alpha-value]
 [, fit_intercept = boolean-value]])
```

## Arguments

### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

The table or view that contains the training data for building the model. If the input relation is defined in Hive, use [SYNC\\_WITH\\_HCATALOG\\_SCHEMA](#) to sync the *hcatalog* schema, and then run the machine learning function.

### **response-column**

The input column that represents the dependent variable or outcome. The column value must be 0 or 1, and of type [numeric](#) or BOOLEAN. The function automatically skips all other values.

### **predictor-columns**

Comma-separated list of columns in the input relation that represent independent variables for the model, or asterisk (\*) to select all columns. If you select all columns, the argument list for parameter *exclude\_columns* must include *response-column*, and any columns that are invalid as predictor columns.

All predictor columns must be of type [numeric](#) or BOOLEAN; otherwise the model is invalid.

#### Note

All BOOLEAN predictor values are converted to FLOAT values before training: 0 for false, 1 for true. No type checking occurs during prediction, so you can use a BOOLEAN predictor column in training, and during prediction provide a FLOAT column of the same name. In this case, all FLOAT values must be either 0 or 1.

## Parameters

### **exclude\_columns**

Comma-separated list of columns from *predictor-columns* to exclude from processing.

### **optimizer**

The optimizer method used to train the model, one of the following:

- [Newton](#)
- [BFGS](#)
- [CGD](#)

Important

If you select *CGD*, *regularization-method* must be set to *L1* or *ENet*, otherwise the function returns an error.

**Default:** *CGD* if *regularization-method* is set to *L1* or *ENet*, otherwise *Newton*.

### **regularization**

The method of regularization, one of the following:

- *None* (default)
- *L1*
- *L2*
- *ENet*

### **epsilon**

FLOAT in the range (0.0, 1.0), the error value at which to stop training. Training stops if either the difference between the actual and predicted values is less than or equal to *epsilon* or if the number of iterations exceeds *max\_iterations*.

**Default:** 1e-6

### **max\_iterations**

INTEGER in the range (0, 1000000), the maximum number of training iterations. Training stops if either the number of iterations exceeds **max\_iterations** or if the difference between the actual and predicted values is less than or equal to **epsilon** .

**Default:** 100

### **lambda**

Integer  $\geq 0$ , specifies the value of the **regularization** parameter.

**Default:** 1

### **alpha**

Integer  $\geq 0$ , specifies the value of the ENET **regularization** parameter, which defines how much L1 versus L2 regularization to provide. A value of 1 is equivalent to L1 and a value of 0 is equivalent to L2.

**Value range:** [0,1]

**Default:** 0.5

### **fit\_intercept**

Boolean, specifies whether the model includes an intercept. By setting to false, no intercept will be used in training the model. Note that setting **fit\_intercept** to false does not work well with the BFGS optimizer.

**Default:** True

Model attributes

### **data**

The data for the function, including:

- **coeffNames** : Name of the coefficients. This starts with intercept and then follows with the names of the predictors in the same order specified in the call.
- **coeff** : Vector of estimated coefficients, with the same order as **coeffNames**
- **stdErr** : Vector of the standard error of the coefficients, with the same order as **coeffNames**
- **zValue** (for logistic regression): Vector of z-values of the coefficients, in the same order as **coeffNames**
- **tValue** (for linear regression): Vector of t-values of the coefficients, in the same order as **coeffNames**
- **pValue** : Vector of p-values of the coefficients, in the same order as **coeffNames**

### **regularization**

Type of regularization to use when training the model.

### **lambda**

Regularization parameter. Higher values enforce stronger regularization. This value must be nonnegative.

### **alpha**

Elastic net mixture parameter.

### **iterations**

Number of iterations that actually occur for the convergence before exceeding **max\_iterations** .

### **skippedRows**

Number of rows of the input relation that were skipped because they contained an invalid value.

### **processedRows**

Total number of input relation rows minus **skippedRows** .

### **callStr**

Value of all input arguments specified when the function was called.

Privileges

Superuser, or SELECT privileges on the input relation

Examples

```
=> SELECT LOGISTIC_REG('myLogisticRegModel', 'mtcars', 'am',
 'mpg, cyl, disp, hp, drat, wt, qsec, vs, gear, carb'
 USING PARAMETERS exclude_columns='hp', optimizer='BFGS', fit_intercept=true);
LOGISTIC_REG
```

Finished in 20 iterations

## MOVING\_AVERAGE

Creates a moving-average (MA) model from a stationary time series with consistent timesteps that can then be used for prediction via [PREDICT\\_MOVING\\_AVERAGE](#).

Moving average models use the errors of previous predictions to make future predictions. More specifically, the user-specified *lag* determines how many previous predictions and errors it takes into account during computation.

Since its input data must be sorted by timestamp, this algorithm is single-threaded.

This is a meta-function. You must call meta-functions in a top-level [SELECT](#) statement.

Behavior type

[Volatile](#)

Syntax

```
MOVING_AVERAGE ('model-name', 'input-relation', 'data-column', 'timestamp-column'
 [USING PARAMETERS
 [q = lags]
 [, missing = "imputation-method"]
 [, regularization = "regularization-method"]
 [, lambda = regularization-value]
 [, compute_mse = boolean]
])
```

Arguments

### **model-name**

Identifies the model to create, where *model-name* conforms to conventions described in [Identifiers](#). It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.

### **input-relation**

The table or view containing the *timestamp-column*.

This algorithm expects a stationary time series as input; using a time series with a mean that shifts over time may lead to weaker results.

### **data-column**

An input column of type NUMERIC that contains the dependent variables or outcomes.

### **timestamp-column**
